6.17.17 HuberRegressor vs Ridge on dataset with strong outliers

Fit Ridge and HuberRegressor on a dataset with outliers.

The example shows that the predictions in ridge are strongly influenced by the outliers present in the dataset. The
Huber regressor is less influenced by the outliers since the model uses the linear loss for these. As the parameter
epsilon is increased for the Huber regressor, the decision function approaches that of the ridge.
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_regression
from sklearn.linear_model import HuberRegressor, Ridge

# Generate toy data.
rng = np.random.RandomState(0)
X, y = make_regression(n_samples=20, n_features=1, random_state=0, noise=4.0,
                       bias=100.0)

# Add four strong outliers to the dataset.
X_outliers = rng.normal(0, 0.5, size=(4, 1))
y_outliers = rng.normal(0, 2.0, size=4)
X_outliers[:, 0] += X.max() + X.mean() / 4.
X_outliers[:, 0] += X.min() - X.mean() / 4.
y_outliers[:, 0] += y.min() - y.mean() / 4.
y_outliers[:, 0] += y.max() + y.mean() / 4.
X = np.vstack((X, X_outliers))
y = np.concatenate((y, y_outliers))

6.17.20 Joint feature selection with multi-task Lasso

The multi-task lasso allows to fit multiple regression problems jointly enforcing the selected features to be the same across tasks. This example simulates sequential measurements, each task is a time instant, and the relevant features vary in amplitude over time while being the same. The multi-task lasso imposes that features that are selected at one time point are select for all time point. This makes feature selection by the Lasso more stable.
import matplotlib.pyplot as plt
import numpy as np
from sklearn.linear_model import MultiTaskLasso, Lasso

rng = np.random.RandomState(42)

# Generate some 2D coefficients with sine waves with random frequency and phase

### 6.17.21 MNIST classification using multinomial logistic + L1

Here we fit a multinomial logistic regression with L1 penalty on a subset of the MNIST digits classification task. We use the SAGA algorithm for this purpose: this a solver that is fast when the number of samples is significantly larger than the number of features and is able to finely optimize non-smooth objective functions which is the case with the L1-penalty. Test accuracy reaches > 0.8, while weight vectors remains sparse and therefore more easily interpretable.

Note that this accuracy of this L1-penalized linear model is significantly below what can be reached by an L2-penalized linear model or a non-linear multi-layer perceptron model on this dataset.
Classification vector for...

Out:
Sparsity with L1 penalty: 79.95%
Test score with L1 penalty: 0.8322
Example run in 18.771 s

6.17.25 Curve Fitting with Bayesian Ridge Regression

Computes a Bayesian Ridge Regression of Sinusoids.

See Bayesian Ridge Regression for more information on the regressor.

In general, when fitting a curve with a polynomial by Bayesian ridge regression, the selection of initial values of the regularization parameters (alpha, lambda) may be important. This is because the regularization parameters are determined by an iterative procedure that depends on initial values.

In this example, the sinusoid is approximated by a polynomial using different pairs of initial values.

When starting from the default values (alpha_init = 1.90, lambda_init = 1.), the bias of the resulting curve is large, and the variance is small. So, lambda_init should be relatively small (1.e-3) so as to reduce the bias.

Also, by evaluating log marginal likelihood (L) of these models, we can determine which one is better. It can be concluded that the model with larger L is more likely.

6.17.26 Theil-Sen Regression

Computes a Theil-Sen Regression on a synthetic dataset.

See Theil-Sen estimator: generalized-median-based estimator for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the Theil-Sen estimator is robust against outliers. It has a breakdown point of about 29.3% in case of a simple linear regression which means that it can tolerate arbitrary corrupted data (outliers) of up to 29.3% in the two-dimensional case.

The estimation of the model is done by calculating the slopes and intercepts of a subpopulation of all possible combinations of \( p \) subsample points. If an intercept is fitted, \( p \) must be greater than or equal to \( n\_features + 1 \). The final slope and intercept is then defined as the spatial median of these slopes and intercepts.

In certain cases Theil-Sen performs better than RANSAC which is also a robust method. This is illustrated in the second example below where outliers with respect to the x-axis perturb RANSAC. Tuning the residual_threshold parameter of RANSAC remedies this but in general a priori knowledge about the data and the nature of the outliers is needed. Due to the computational complexity of Theil-Sen it is recommended to use it only for small problems in terms of number of samples and features. For larger problems the max_subpopulation parameter restricts the magnitude of all possible combinations of \( p \) subsample points to a randomly chosen subset and therefore also limits the runtime. Therefore, Theil-Sen is applicable to larger problems with the drawback of losing some of its mathematical properties since it then works on a random subset.

6.17.28 Robust linear estimator fitting

Here a sine function is fit with a polynomial of order 3, for values close to zero.

Robust fitting is demoed in different situations:

- No measurement errors, only modelling errors (fitting a sine with a polynomial)
- Measurement errors in X
- Measurement errors in y

The median absolute deviation to non corrupt new data is used to judge the quality of the prediction.

What we can see that:

- RANSAC is good for strong outliers in the y direction
- TheilSen is good for small outliers, both in direction X and y, but has a break point above which it performs worse than OLS.
- The scores of HuberRegressor may not be compared directly to both TheilSen and RANSAC because it does not attempt to completely filter the outliers but lessen their effect.

6.17.29 L1 Penalty and Sparsity in Logistic Regression

Comparison of the sparsity (percentage of zero coefficients) of solutions when L1, L2 and Elastic-Net penalty are used for different values of C. We can see that large values of C give more freedom to the model. Conversely, smaller values of C constrain the model more. In the L1 penalty case, this leads to sparser solutions. As expected, the Elastic-Net penalty sparsity is between that of L1 and L2.

We classify 8x8 images of digits into two classes: 0-4 against 5-9. The visualization shows coefficients of the models for varying C.

6.17.31 Automatic Relevance Determination Regression (ARD)

Fit regression model with Bayesian Ridge Regression.

See Bayesian Ridge Regression for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the coefficient weights are slightly shifted toward zeros, which stabilises them.

The histogram of the estimated weights is very peaked, as a sparsity-inducing prior is implied on the weights.

The estimation of the model is done by iteratively maximizing the marginal log-likelihood of the observations.

We also plot predictions and uncertainties for ARD for one dimensional regression using polynomial feature expansion. Note the uncertainty starts going up on the right side of the plot. This is because these test samples are outside of the range of the training samples.

6.17.33 Lasso model selection: Cross-Validation / AIC / BIC

Use the Akaike information criterion (AIC), the Bayes Information criterion (BIC) and cross-validation to select an optimal value of the regularization parameter alpha of the Lasso estimator.

Results obtained with LassoLarsIC are based on AIC/BIC criteria.

Information-criterion based model selection is very fast, but it relies on a proper estimation of degrees of freedom, are derived for large samples (asymptotic results) and assume the model is correct, i.e. that the data are actually generated by this model. They also tend to break when the problem is badly conditioned (more features than samples).

For cross-validation, we use 20-fold with 2 algorithms to compute the Lasso path: coordinate descent, as implemented by the LassoCV class, and Lars (least angle regression) as implemented by the LassoLarsCV class. Both algorithms give roughly the same results. They differ with regards to their execution speed and sources of numerical errors.

Lars computes a path solution only for each kink in the path. As a result, it is very efficient when there are only of few kinks, which is the case if there are few features or samples. Also, it is able to compute the full path without setting any meta parameter. On the opposite, coordinate descent compute the path points on a pre-specified grid (here we use the default). Thus it is more efficient if the number of grid points is smaller than the number of kinks in the path. Such a strategy can be interesting if the number of features is really large and there are enough samples to select a large amount. In terms of numerical errors, for heavily correlated variables, Lars will accumulate more errors, while the coordinate descent algorithm will only sample the path on a grid.

Note how the optimal value of alpha varies for each fold. This illustrates why nested-cross validation is necessary when trying to evaluate the performance of a method for which a parameter is chosen by cross-validation: this choice of parameter may not be optimal for unseen data.
Mean square error on each fold: coordinate descent (train time: 0.23s)

- **Average across the folds**
- **alpha: CV estimate**

```
import matplotlib.pyplot as plt
import numpy as np
import scikit_learn

# Data for the example
x = np.arange(10)
y = np.array([1, 2, 3, 4, 5, 6, 7, 8, 9, 10])

# Computing the mean square error for each fold
mse = np.mean((y - x) ** 2, axis=1)

# Plotting the results
plt.figure()
plt.plot(x, mse, label='Average across the folds')
plt.plot(x, mse[-1], label='alpha: CV estimate')
plt.xlabel(r'$\alpha$')
plt.ylabel('Mean square error')

6.17.34 Multiclass sparse logistic regression on 20newsgroups

Comparison of multinomial logistic L1 vs one-versus-rest L1 logistic regression to classify documents from the newsgroups20 dataset. Multinomial logistic regression yields more accurate results and is faster to train on the larger scale dataset.

Here we use the L1 sparsity that trims the weights of not informative features to zero. This is good if the goal is to extract the strongly discriminative vocabulary of each class. If the goal is to get the best predictive accuracy, it is better to use the non sparsity-inducing L2 penalty instead.

A more traditional (and possibly better) way to predict on a sparse subset of input features would be to use univariate feature selection followed by a traditional (L2-penalised) logistic regression model.

6.17.35 Early stopping of Stochastic Gradient Descent

Stochastic Gradient Descent is an optimization technique which minimizes a loss function in a stochastic fashion, performing a gradient descent step sample by sample. In particular, it is a very efficient method to fit linear models.

As a stochastic method, the loss function is not necessarily decreasing at each iteration, and convergence is only guaranteed in expectation. For this reason, monitoring the convergence on the loss function can be difficult.

Another approach is to monitor convergence on a validation score. In this case, the input data is split into a training set and a validation set. The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set. This enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data and reduces the chance of over-fitting the training data.

This early stopping strategy is activated if `early_stopping=True`; otherwise the stopping criterion only uses the training loss on the entire input data. To better control the early stopping strategy, we can specify a parameter `validation_fraction` which set the fraction of the input dataset that we keep aside to compute the validation score. The optimization will continue until the validation score did not improve by at least `tol` during the last `n_iter_no_change` iterations. The actual number of iterations is available at the attribute `n_iter_`.

This example illustrates how the early stopping can be used in the `SGDClassifier` model to achieve almost the same accuracy as compared to a model built without early stopping. This can significantly reduce training time. Note that scores differ between the stopping criteria even from early iterations because some of the training data is held out with the validation stopping criterion.

6.17.36 Poisson regression and non-normal loss

This example illustrates the use of log-linear Poisson regression on the French Motor Third-Party Liability Claims dataset from¹ and compares it with a linear model fitted with the usual least squared error and a non-linear GBRT model fitted with the Poisson loss (and a log-link).

A few definitions:

- A **policy** is a contract between an insurance company and an individual: the **policyholder**, that is, the vehicle driver in this case.
- A **claim** is the request made by a policyholder to the insurer to compensate for a loss covered by the insurance.
- The **exposure** is the duration of the insurance coverage of a given policy, in years.
- The **claim frequency** is the number of claims divided by the exposure, typically measured in number of claims per year.

In this dataset, each sample corresponds to an insurance policy. Available features include driver age, vehicle age, vehicle power, etc.

Our goal is to predict the expected frequency of claims following car accidents for a new policyholder given the historical data over a population of policyholders.

---

The number of claims (ClaimNb) is a positive integer that can be modeled as a Poisson distribution. It is then assumed to be the number of discrete events occurring with a constant rate in a given time interval (Exposure, in units of years).

Here we want to model the frequency $y = \text{ClaimNb} / \text{Exposure}$ conditionally on $X$ via a (scaled) Poisson distribution, and use Exposure as sample_weight.

```python
df["Frequency"] = df["ClaimNb"] / df["Exposure"]

print("Average Frequency = {}\n   .format(np.average(df["Frequency"], weights=df["Exposure"])))

print("Fraction of exposure with zero claims = {}\n   .format(df.loc[df["ClaimNb"] == 0, "Exposure"].sum() /
   df["Exposure"].sum()))
```

```
fig, (ax0, ax1, ax2) = plt.subplots(ncols=3, figsize=(16, 4))
ax0.set_title("Number of claims")
_ = df["ClaimNb"].hist(bins=30, log=True, ax=ax0)
ax1.set_title("Exposure in years")
_ = df["Exposure"].hist(bins=30, log=True, ax=ax1)
ax2.set_title("Frequency (number of claims per year)")
_ = df["Frequency"].hist(bins=30, log=True, ax=ax2)
```

```
Out:
Average Frequency = 0.10070308464041304
Fraction of exposure with zero claims = 93.9%
```

The remaining columns can be used to predict the frequency of claim events. Those columns are very heterogeneous with a mix of categorical and numeric variables with different scales, possibly very unevenly distributed.

In order to fit linear models with those predictors it is therefore necessary to perform standard feature transformations as follows:

```python
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import FunctionTransformer, OneHotEncoder
from sklearn.preprocessing import StandardScaler, KBinsDiscretizer
from sklearn.compose import ColumnTransformer

log_scale_transformer = make_pipeline(
    FunctionTransformer(np.log, validate=False),
    StandardScaler()
)

linear_model_preprocessor = ColumnTransformer(
```

(continues on next page)
A constant prediction baseline

It is worth noting that more than 93% of policyholders have zero claims. If we were to convert this problem into a binary classification task, it would be significantly imbalanced, and even a simplistic model that would only predict mean can achieve an accuracy of 93%.

To evaluate the pertinence of the used metrics, we will consider as a baseline a “dummy” estimator that constantly predicts the mean frequency of the training sample.

```python
from sklearn.dummy import DummyRegressor
from sklearn.pipeline import Pipeline
from sklearn.model_selection import train_test_split

df_train, df_test = train_test_split(df, test_size=0.33, random_state=0)

dummy = Pipeline([  
    ("preprocessor", linear_model_preprocessor),
    ("regressor", DummyRegressor(strategy='mean')),
]).fit(df_train, df_train["Frequency"], regressor__sample_weight=df_train["Exposure"])
```

Let’s compute the performance of this constant prediction baseline with 3 different regression metrics:

```python
from sklearn.metrics import mean_squared_error
from sklearn.metrics import mean_absolute_error
from sklearn.metrics import mean_poisson_deviance

def score_estimator(estimator, df_test):
    
    y_pred = estimator.predict(df_test)
    
    print("MSE: 
        mean_squared_error(df_test["Frequency"], y_pred, 
                        sample_weight=df_test["Exposure"]))

    print("MAE: 
        mean_absolute_error(df_test["Frequency"], y_pred, 
                        sample_weight=df_test["Exposure"]))

    # Ignore non-positive predictions, as they are invalid for 
    # the Poisson deviance.
    mask = y_pred > 0
```

(continues on next page)
if (~mask).any():
    n_masked, n_samples = (~mask).sum(), mask.shape[0]
    print(f"WARNING: Estimator yields invalid, non-positive predictions "
          f"for {n_masked} samples out of {n_samples}. These predictions "
          f"are ignored when computing the Poisson deviance."
    
    print("mean Poisson deviance: %.3f" %
          mean_poisson_deviance(df_test["Frequency"][mask],
                                y_pred[mask],
                                sample_weight=df_test["Exposure"][mask]))

print("Constant mean frequency evaluation:")
score_estimator(dummy, df_test)

Out:

Constant mean frequency evaluation:
MSE: 0.564
MAE: 0.189
mean Poisson deviance: 0.625

(Generalized) linear models

We start by modeling the target variable with the (l2 penalized) least squares linear regression model, more commonly known as Ridge regression. We use a low penalization alpha, as we expect such a linear model to under-fit on such a large dataset.

from sklearn.linear_model import Ridge

ridge_glm = Pipeline([
    ("preprocessor", linear_model_preprocessor),
    ("regressor", Ridge(alpha=1e-6)),
]).fit(df_train, df_train["Frequency"],
      regressor__sample_weight=df_train["Exposure"]
)

The Poisson deviance cannot be computed on non-positive values predicted by the model. For models that do return a few non-positive predictions (e.g. Ridge) we ignore the corresponding samples, meaning that the obtained Poisson deviance is approximate. An alternative approach could be to use TransformedTargetRegressor meta-estimator to map y_pred to a strictly positive domain.

print("Ridge evaluation:")
score_estimator(ridge_glm, df_test)

Out:

Ridge evaluation:
MSE: 0.560
MAE: 0.177
WARNING: Estimator yields invalid, non-positive predictions for 1315 samples out of 223745. These predictions are ignored when computing the Poisson deviance.
mean Poisson deviance: 0.601
Next we fit the Poisson regressor on the target variable. We set the regularization strength $\alpha$ to approximately $1e-6$ over number of samples (i.e. $1e-12$) in order to mimic the Ridge regressor whose L2 penalty term scales differently with the number of samples.

Since the Poisson regressor internally models the log of the expected target value instead of the expected value directly (log vs identity link function), the relationship between $X$ and $y$ is not exactly linear anymore. Therefore the Poisson regressor is called a Generalized Linear Model (GLM) rather than a vanilla linear model as is the case for Ridge regression.

```python
from sklearn.linear_model import PoissonRegressor

n_samples = df_train.shape[0]

poisson_glm = Pipeline([  
    ("preprocessor", linear_model_preprocessor),  
    ("regressor", PoissonRegressor(alpha=1e-12, max_iter=300))  
])

poisson_glm.fit(df_train, df_train["Frequency"],  
                 regressor__sample_weight=df_train["Exposure"])

print("PoissonRegressor evaluation:")
score_estimator(poisson_glm, df_test)
```

Out:
```
PoissonRegressor evaluation:  
MSE: 0.560  
MAE: 0.186  
mean Poisson deviance: 0.594
```

### Gradient Boosting Regression Trees for Poisson regression

Finally, we will consider a non-linear model, namely Gradient Boosting Regression Trees. Tree-based models do not require the categorical data to be one-hot encoded: instead, we can encode each category label with an arbitrary integer using `OrdinalEncoder`. With this encoding, the trees will treat the categorical features as ordered features, which might not be always a desired behavior. However this effect is limited for deep enough trees which are able to recover the categorical nature of the features. The main advantage of the `OrdinalEncoder` over the `OneHotEncoder` is that it will make training faster.

Gradient Boosting also gives the possibility to fit the trees with a Poisson loss (with an implicit log-link function) instead of the default least-squares loss. Here we only fit trees with the Poisson loss to keep this example concise.

```python
from sklearn.experimental import enable_hist_gradient_boosting  
# noqa
from sklearn.ensemble import HistGradientBoostingRegressor
from sklearn.preprocessing import OrdinalEncoder

tree_preprocessor = ColumnTransformer(  
    [  
      ("categorical", OrdinalEncoder(),  
       ["VehBrand", "VehPower", "VehGas", "Region", "Area"]),  
      ("numeric", "passthrough",  
       ["VehAge", "DrivAge", "BonusMalus", "Density"]),  
    ],  
    remainder="drop",  
)
```

(continues on next page)
poisson_gbrt = Pipeline([  
    ("preprocessor", tree_preprocessor),  
    ("regressor", HistGradientBoostingRegressor(loss="poisson",  
        max_leaf_nodes=128)),  
])
poisson_gbrt.fit(df_train, df_train["Frequency"],  
    regressor__sample_weight=df_train["Exposure"])

print("Poisson Gradient Boosted Trees evaluation:")
score_estimator(poisson_gbrt, df_test)

Out:

Poisson Gradient Boosted Trees evaluation:
MSE: 0.560
MAE: 0.184
mean Poisson deviance: 0.575

Like the Poisson GLM above, the gradient boosted trees model minimizes the Poisson deviance. However, because of  
a higher predictive power, it reaches lower values of Poisson deviance.

Evaluating models with a single train / test split is prone to random fluctuations. If computing resources allow, it  
should be verified that cross-validated performance metrics would lead to similar conclusions.

The qualitative difference between these models can also be visualized by comparing the histogram of observed target  
values with that of predicted values:

```python
fig, axes = plt.subplots(nrows=2, ncols=4, figsize=(16, 6), sharey=True)
fig.subplots_adjust(bottom=0.2)
n_bins = 20
for row_idx, label, df in zip(range(2),  
    ["train", "test"],  
    [df_train, df_test]):  
    df["Frequency"].hist(bins=np.linspace(-1, 30, n_bins),  
        ax=axes[row_idx, 0])
    axes[row_idx, 0].set_title("Data")
    axes[row_idx, 0].set_yscale('log')
    axes[row_idx, 0].set_xlabel("y (observed Frequency)")
    axes[row_idx, 0].set_ylabel(label + " samples")

for idx, model in enumerate([ridge_glm, poisson_glm, poisson_gbrt]):  
    y_pred = model.predict(df)
    pd.Series(y_pred).hist(bins=np.linspace(-1, 4, n_bins),  
        ax=axes[row_idx, idx+1])
    axes[row_idx, idx+1].set(  
        title=model[-1].__class__.__name__,  
        yscale='log',  
        xlabel="y_pred (predicted expected Frequency)"
)
plt.tight_layout()
```
The experimental data presents a long tail distribution for \( y \). In all models, we predict the expected frequency of a random variable, so we will have necessarily fewer extreme values than for the observed realizations of that random variable. This explains that the mode of the histograms of model predictions doesn’t necessarily correspond to the smallest value. Additionally, the normal distribution used in Ridge has a constant variance, while for the Poisson distribution used in PoissonRegressor and HistGradientBoostingRegressor, the variance is proportional to the predicted expected value.

Thus, among the considered estimators, PoissonRegressor and HistGradientBoostingRegressor are a-priori better suited for modeling the long tail distribution of the non-negative data as compared to the Ridge model which makes a wrong assumption on the distribution of the target variable.

The HistGradientBoostingRegressor estimator has the most flexibility and is able to predict higher expected values.

Note that we could have used the least squares loss for the HistGradientBoostingRegressor model. This would wrongly assume a normal distributed response variable as does the Ridge model, and possibly also lead to slightly negative predictions. However the gradient boosted trees would still perform relatively well and in particular better than PoissonRegressor thanks to the flexibility of the trees combined with the large number of training samples.

**Evaluation of the calibration of predictions**

To ensure that estimators yield reasonable predictions for different policyholder types, we can bin test samples according to \( y_{\text{pred}} \) returned by each model. Then for each bin, we compare the mean predicted \( y_{\text{pred}} \), with the mean observed target:

```python
from sklearn.utils import gen_even_slices

def _mean_frequency_by_risk_group(y_true, y_pred, sample_weight=None, n_bins=100):
    """Compare predictions and observations for bins ordered by y_pred.

    We order the samples by `y_pred` and split it in bins.
    In each bin the observed mean is compared with the predicted mean.

    Parameters
    ----------
    y_true: array-like of shape (n_samples,)
        Ground truth (correct) target values.
    y_pred: array-like of shape (n_samples,)
        Predicted target values.
    sample_weight: array-like of shape (n_samples,)
        Sample weights.
    n_bins: int
        Number of bins.
    """
    # (Continues on next page)
```
y_pred: array-like of shape (n_samples,)
   Estimated target values.
sample_weight: array-like of shape (n_samples,)
   Sample weights.
n_bins: int
   Number of bins to use.

Returns
-------
bin_centers: ndarray of shape (n_bins,)
   bin centers
y_true_bin: ndarray of shape (n_bins,)
   average y_true for each bin
y_pred_bin: ndarray of shape (n_bins,)
   average y_pred for each bin

idx_sort = np.argsort(y_pred)
bin_centers = np.arange(0, 1, 1/n_bins) + 0.5/n_bins
y_pred_bin = np.zeros(n_bins)
y_true_bin = np.zeros(n_bins)

for n, sl in enumerate(gen_even_slices(len(y_true), n_bins)):
    weights = sample_weight[idx_sort][sl]
    y_pred_bin[n] = np.average(y_pred[idx_sort][sl], weights=weights)
    y_true_bin[n] = np.average(y_true[idx_sort][sl], weights=weights)
return bin_centers, y_true_bin, y_pred_bin

print(f"Actual number of claims: {df_test['ClaimNb'].sum()}")
fig, ax = plt.subplots(nrows=2, ncols=2, figsize=(12, 8))
plt.subplots_adjust(wspace=0.3)
for axi, model in zip(ax.ravel(), [ridge_glm, poisson_glm, poisson_gbrt, dummy]):
    y_pred = model.predict(df_test)
y_true = df_test['Frequency'].values
exposure = df_test['Exposure'].values
q, y_true_seg, y_pred_seg = _mean_frequency_by_risk_group(
    y_true, y_pred, sample_weight=exposure, n_bins=10)

# Name of the model after the estimator used in the last step of the # pipeline.
print(f"Predicted number of claims by {model[-1]}: ",
    f"{np.sum(y_pred * exposure):.1f}" )
axi.plot(q, y_pred_seg, marker='x', linestyle='--', label="predictions")
axi.plot(q, y_true_seg, marker='o', linestyle='--', label="observations")
axi.set_xlim(0, 1.0)
axi.set_ylim(0, 0.5)
axi.set(
    title=model[-1],
xlabel='Fraction of samples sorted by y_pred',
(continues on next page)
ylabel='Mean Frequency (y_pred)'
)
axi.legend()
plt.tight_layout()

Out:

Actual number of claims: 11935.0
Predicted number of claims by Ridge(alpha=1e-06): 10692.9
Predicted number of claims by PoissonRegressor(alpha=1e-12, max_iter=300): 11932.0
Predicted number of claims by HistGradientBoostingRegressor(loss='poisson', max_leaf_nodes=128): 12109.6
Predicted number of claims by DummyRegressor(): 11931.2

The dummy regression model predicts a constant frequency. This model does not attribute the same tied rank to all samples but is none-the-less globally well calibrated (to estimate the mean frequency of the entire population).

The Ridge regression model can predict very low expected frequencies that do not match the data. It can therefore severely under-estimate the risk for some policyholders.

PoissonRegressor and HistGradientBoostingRegressor show better consistency between predicted and observed targets, especially for low predicted target values.

The sum of all predictions also confirms the calibration issue of the Ridge model: it under-estimates by more than 3% the total number of claims in the test set while the other three models can approximately recover the total number of claims of the test portfolio.
Evaluation of the ranking power

For some business applications, we are interested in the ability of the model to rank the riskiest from the safest policyholders, irrespective of the absolute value of the prediction. In this case, the model evaluation would cast the problem as a ranking problem rather than a regression problem.

To compare the 3 models from this perspective, one can plot the cumulative proportion of claims vs the cumulative proportion of exposure for the test samples order by the model predictions, from safest to riskiest according to each model.

This plot is called a Lorenz curve and can be summarized by the Gini index:

```python
from sklearn.metrics import auc

def lorenz_curve(y_true, y_pred, exposure):
    y_true, y_pred = np.asarray(y_true), np.asarray(y_pred)
    exposure = np.asarray(exposure)

    # order samples by increasing predicted risk:
    ranking = np.argsort(y_pred)
    ranked_frequencies = y_true[ranking]
    ranked_exposure = exposure[ranking]
    cumulated_claims = np.cumsum(ranked_frequencies * ranked_exposure)
    cumulated_claims /= cumulated_claims[-1]
    cumulated_exposure = np.cumsum(ranked_exposure)
    cumulated_exposure /= cumulated_exposure[-1]

    return cumulated_exposure, cumulated_claims

fig, ax = plt.subplots(figsize=(8, 8))

for model in [dummy, ridge_glm, poisson_glm, poisson_gbrt]:
    y_pred = model.predict(df_test)
    cum_exposure, cum_claims = lorenz_curve(df_test["Frequency"], y_pred,
                                            df_test["Exposure"])
    gini = 1 - 2 * auc(cum_exposure, cum_claims)
    label = "{} (Gini: {:.2f})".format(model[-1], gini)
    ax.plot(cum_exposure, cum_claims, linestyle="-", label=label)

# Oracle model: y_pred == y_test
cum_exposure, cum_claims = lorenz_curve(df_test["Frequency"],
                                        df_test["Exposure"],
                                        df_test["Exposure"])
    gini = 1 - 2 * auc(cum_exposure, cum_claims)
    label = "Oracle (Gini: {:.2f})".format(gini)
    ax.plot(cum_exposure, cum_claims, linestyle="-.", color="gray", label=label)

# Random Baseline
ax.plot([0, 1], [0, 1], linestyle="--", color="black",
        label="Random baseline")
ax.set(
    title="Lorenz curves by model",
    xlabel='Cumulative proportion of exposure (from safest to riskiest)',
    ylabel='Cumulative proportion of claims')
ax.legend(loc="upper left")
```
As expected, the dummy regressor is unable to correctly rank the samples and therefore performs the worst on this plot.

The tree-based model is significantly better at ranking policyholders by risk while the two linear models perform similarly.

All three models are significantly better than chance but also very far from making perfect predictions.

This last point is expected due to the nature of the problem: the occurrence of accidents is mostly dominated by circumstantial causes that are not captured in the columns of the dataset and can indeed be considered as purely random.
The linear models assume no interactions between the input variables which likely causes under-fitting. Inserting a polynomial feature extractor (`PolynomialFeatures`) indeed increases their discriminative power by 2 points of Gini index. In particular it improves the ability of the models to identify the top 5% riskiest profiles.

**Main takeaways**

- The performance of the models can be evaluated by their ability to yield well-calibrated predictions and a good ranking.
- The calibration of the model can be assessed by plotting the mean observed value vs the mean predicted value on groups of test samples binned by predicted risk.
- The least squares loss (along with the implicit use of the identity link function) of the Ridge regression model seems to cause this model to be badly calibrated. In particular, it tends to underestimate the risk and can even predict invalid negative frequencies.
- Using the Poisson loss with a log-link can correct these problems and lead to a well-calibrated linear model.
- The Gini index reflects the ability of a model to rank predictions irrespective of their absolute values, and therefore only assess their ranking power.
- Despite the improvement in calibration, the ranking power of both linear models are comparable and well below the ranking power of the Gradient Boosting Regression Trees.
- The Poisson deviance computed as an evaluation metric reflects both the calibration and the ranking power of the model. It also makes a linear assumption on the ideal relationship between the expected value and the variance of the response variable. For the sake of conciseness we did not check whether this assumption holds.
- Traditional regression metrics such as Mean Squared Error and Mean Absolute Error are hard to meaningfully interpret on count values with many zeros.

```python
plt.show()
```

### 6.17.37 Tweedie regression on insurance claims

This example illustrates the use of Poisson, Gamma and Tweedie regression on the French Motor Third-Party Liability Claims dataset, and is inspired by an R tutorial\(^1\).

In this dataset, each sample corresponds to an insurance policy, i.e. a contract within an insurance company and an individual (policyholder). Available features include driver age, vehicle age, vehicle power, etc.

A few definitions: a *claim* is the request made by a policyholder to the insurer to compensate for a loss covered by the insurance. The *claim amount* is the amount of money that the insurer must pay. The *exposure* is the duration of the insurance coverage of a given policy, in years.

Here our goal is to predict the expected value, i.e. the mean, of the total claim amount per exposure unit also referred to as the pure premium.

There are several possibilities to do that, two of which are:

1. Model the number of claims with a Poisson distribution, and the average claim amount per claim, also known as severity, as a Gamma distribution and multiply the predictions of both in order to get the total claim amount.
2. Model the total claim amount per exposure directly, typically with a Tweedie distribution of Tweedie power \(p \in (1, 2)\).

In this example we will illustrate both approaches. We start by defining a few helper functions for loading the data and visualizing results.

```python
from sklearn.datasets import fetch_openml
from sklearn.preprocessing import FunctionTransformer
from sklearn.metrics import mean_absolute_error, mean_squared_error

def load_mtpl2(n_samples=100000):
    """Fetch the French Motor Third-Party Liability Claims dataset."
    df_freq = fetch_openml(data_id=41214, as_frame=True)['data']
    df_freq['IDpol'] = df_freq['IDpol'].astype(int)
    df_freq.set_index('IDpol', inplace=True)
    df_sev = fetch_openml(data_id=41215, as_frame=True)['data']
    df_sev = df_sev.groupby('IDpol').sum()
    df = df_freq.join(df_sev, how="left")
    df['ClaimAmount'].fillna(0, inplace=True)
    for column_name in df.columns[df.dtypes.values == object]:
        df[column_name] = df[column_name].str.strip('"
    return df.iloc[:n_samples]
```

```python
def plot_obs_pred(df, feature, weight, observed, predicted, y_label=None):
    """Plot observed and predicted values for a feature."
    plt.plot(df[feature], df[observed], label='Observed')
    plt.plot(df[feature], df[predicted], label='Predicted')
    plt.xlabel('Feature')
    plt.ylabel(y_label or 'Value')
    plt.legend()
```

(continues on next page)

Frequency model – Poisson distribution

The number of claims (ClaimNb) is a positive integer (0 included). Thus, this target can be modelled by a Poisson distribution. It is then assumed to be the number of discrete events occurring with a constant rate in a given time interval (Exposure, in units of years). Here we model the frequency \( y = \frac{\text{ClaimNb}}{\text{Exposure}} \), which is still a (scaled) Poisson distribution, and use Exposure as sample_weight.

```python
df_train, df_test, X_train, X_test = train_test_split(df, X, random_state=0)

# The parameters of the model are estimated by minimizing the Poisson deviance # on the training set via a quasi-Newton solver: l-BFGS. Some of the features # are collinear, we use a weak penalization to avoid numerical issues.
glm_freq = PoissonRegressor(alpha=1e-3, max_iter=400)
glm_freq.fit(X_train, df_train["Frequency"],
             sample_weight=df_train["Exposure"])

scores = score_estimator(
    glm_freq,
    X_train,
    X_test,
    df_train,
    df_test,
    target="Frequency",
    weights="Exposure",
)

print("Evaluation of PoissonRegressor on target Frequency")
print(scores)
```

Out:

```
Evaluation of PoissonRegressor on target Frequency
subset train test
metric             D^2 explained  mean abs. error  mean squared error
                   0.0590    0.1706       0.3041
```

6.17. Generalized Linear Models
We can visually compare observed and predicted values, aggregated by the drivers age (DrivAge), vehicle age (VehAge) and the insurance bonus/malus (BonusMalus).

```python
fig, ax = plt.subplots(ncols=2, nrows=2, figsize=(16, 8))
fig.subplots_adjust(hspace=0.3, wspace=0.2)
plot_obs_pred(
    df=df_train,
    feature="DrivAge",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_train),
    y_label="Claim Frequency",
    title="train data",
    ax=ax[0, 0],
)
plot_obs_pred(
    df=df_test,
    feature="DrivAge",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_test),
    y_label="Claim Frequency",
    title="test data",
    ax=ax[0, 1],
    fill_legend=True
)
plot_obs_pred(
    df=df_test,
    feature="VehAge",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_test),
    y_label="Claim Frequency",
    title="test data",
    ax=ax[1, 0],
    fill_legend=True
)
plot_obs_pred(
    df=df_test,
    feature="BonusMalus",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_test),
    y_label="Claim Frequency",
    title="test data",
    ax=ax[1, 1],
    fill_legend=True
)
```
According to the observed data, the frequency of accidents is higher for drivers younger than 30 years old, and is positively correlated with the `BonusMalus` variable. Our model is able to mostly correctly model this behaviour.

### Severity Model - Gamma distribution

The mean claim amount or severity (`AvgClaimAmount`) can be empirically shown to follow approximately a Gamma distribution. We fit a GLM model for the severity with the same features as the frequency model.

**Note:**
- We filter out `ClaimAmount == 0` as the Gamma distribution has support on $(0, \infty)$, not $[0, \infty)$.
- We use `ClaimNb` as `sample_weight` to account for policies that contain more than one claim.

```python
mask_train = df_train["ClaimAmount"] > 0
mask_test = df_test["ClaimAmount"] > 0

glm_sev = GammaRegressor(alpha=10., max_iter=10000)

glm_sev.fit(
    X_train[mask_train.values],
    df_train.loc[mask_train, "AvgClaimAmount"],
    sample_weight=df_train.loc[mask_train, "ClaimNb"],
)

scores = score_estimator(
    glm_sev,
    X_train[mask_train.values],
    X_test[mask_test.values],
    df_train[mask_train],
    df_test[mask_test],
    target="AvgClaimAmount",
    weights="ClaimNb",
)

print("Evaluation of GammaRegressor on target AvgClaimAmount")
print(scores)
```
Evaluation of GammaRegressor on target AvgClaimAmount subset train test

<table>
<thead>
<tr>
<th>metric</th>
<th>train</th>
<th>test</th>
</tr>
</thead>
<tbody>
<tr>
<td>D^2 explained</td>
<td>4.300000e-03</td>
<td>-1.380000e-02</td>
</tr>
<tr>
<td>mean abs. error</td>
<td>1.699197e+03</td>
<td>2.027923e+03</td>
</tr>
<tr>
<td>mean squared error</td>
<td>4.548147e+07</td>
<td>6.094863e+07</td>
</tr>
</tbody>
</table>

Here, the scores for the test data call for caution as they are significantly worse than for the training data indicating an overfit despite the strong regularization.

Note that the resulting model is the average claim amount per claim. As such, it is conditional on having at least one claim, and cannot be used to predict the average claim amount per policy in general.

```python
print("Mean AvgClaim Amount per policy: %.2f " % df_train["AvgClaimAmount"].mean())
print("Mean AvgClaim Amount | NbClaim > 0: %.2f" % df_train["AvgClaimAmount"]\[df_train["AvgClaimAmount"] > 0].mean())
print("Predicted Mean AvgClaim Amount | NbClaim > 0: %.2f" % glm_sev.predict(X_train).mean())
```

Out:

| Mean AvgClaim Amount per policy: | 97.89 |
| Mean AvgClaim Amount | NbClaim > 0: | 1899.60 |
| Predicted Mean AvgClaim Amount | NbClaim > 0: | 1884.40 |

We can visually compare observed and predicted values, aggregated for the drivers age (DrivAge).

```python
fig, ax = plt.subplots(ncols=1, nrows=2, figsize=(16, 6))
plot_obs_pred(df=df_train.loc[mask_train], feature="DrivAge", weight="Exposure", observed="AvgClaimAmount", predicted=glm_sev.predict(X_train[mask_train.values]), y_label="Average Claim Severity", title="train data", ax=ax[0],)
plot_obs_pred(df=df_test.loc[mask_test], feature="DrivAge", weight="Exposure", observed="AvgClaimAmount", predicted=glm_sev.predict(X_test[mask_test.values]), y_label="Average Claim Severity", title="test data", ax=ax[1], fill_legend=True)
plt.tight_layout()
```

1248 Chapter 6. Examples
Overall, the drivers age (DrivAge) has a weak impact on the claim severity, both in observed and predicted data.

**Pure Premium Modeling via a Product Model vs single TweedieRegressor**

As mentioned in the introduction, the total claim amount per unit of exposure can be modeled as the product of the prediction of the frequency model by the prediction of the severity model. Alternatively, one can directly model the total loss with a unique Compound Poisson Gamma generalized linear model (with a log link function). This model is a special case of the Tweedie GLM with a “power” parameter $p \in (1, 2)$. Here, we fix a priori the power parameter of the Tweedie model to some arbitrary value (1.9) in the valid range. Ideally one would select this value via grid-search by minimizing the negative log-likelihood of the Tweedie model, but unfortunately the current implementation does not allow for this (yet).

We will compare the performance of both approaches. To quantify the performance of both models, one can compute the mean deviance of the train and test data assuming a Compound Poisson-Gamma distribution of the total claim amount. This is equivalent to a Tweedie distribution with a power parameter between 1 and 2.

The `sklearn.metrics.mean_tweedie_deviance` depends on a power parameter. As we do not know the true value of the power parameter, we here compute the mean deviances for a grid of possible values, and compare the models side by side, i.e. we compare them at identical values of power. Ideally, we hope that one model will be consistently better than the other, regardless of power.

```python
glm_pure_premium = TweedieRegressor(power=1.9, alpha=.1, max_iter=10000)
glm_pure_premium.fit(X_train, df_train["PurePremium"],
    sample_weight=df_train["Exposure"])

tweedie_powers = [1.5, 1.7, 1.8, 1.9, 1.99, 1.999, 1.9999]

scores_product_model = score_estimator(
    glm_freq, glm_sev),
    X_train,
    X_test,
    df_train,
    df_test,
    target="PurePremium",
    weights="Exposure",
    tweedie_powers=tweedie_powers,
)

scores_glm_pure_premium = score_estimator(
    (continues on next page)
)```
In this example, both modeling approaches yield comparable performance metrics. For implementation reasons, the percentage of explained variance $D^2$ is not available for the product model.

We can additionally validate these models by comparing observed and predicted total claim amount over the test and train subsets. We see that, on average, both model tend to underestimate the total claim (but this behavior depends on the amount of regularization).

```python
res = []
for subset_label, X, df in [  
    ("train", X_train, df_train),  
    ("test", X_test, df_test),  
]:
    exposure = df["Exposure"].values
    res.append(
        {
            "subset": subset_label,
            "observed": df["ClaimAmount"].values.sum(),
            "predicted, frequency*severity model": np.sum(
                exposure * glm_freq.predict(X) * glm_sev.predict(X)
            ),
            "predicted, tweedie, power=%.2f" % glm_pure_premium.power: np.sum(
                exposure * glm_pure_premium.predict(X)
            ),
        }
    )
```

Out:

```

In this example, both modeling approaches yield comparable performance metrics. For implementation reasons, the percentage of explained variance $D^2$ is not available for the product model.

We can additionally validate these models by comparing observed and predicted total claim amount over the test and train subsets. We see that, on average, both model tend to underestimate the total claim (but this behavior depends on the amount of regularization).

```python
res = []
for subset_label, X, df in [  
    ("train", X_train, df_train),  
    ("test", X_test, df_test),  
]:
    exposure = df["Exposure"].values
    res.append(
        {
            "subset": subset_label,
            "observed": df["ClaimAmount"].values.sum(),
            "predicted, frequency*severity model": np.sum(
                exposure * glm_freq.predict(X) * glm_sev.predict(X)
            ),
            "predicted, tweedie, power=%.2f" % glm_pure_premium.power: np.sum(
                exposure * glm_pure_premium.predict(X)
            ),
        }
    )
```

(continues on next page)
Finally, we can compare the two models using a plot of cumulated claims: for each model, the policyholders are ranked from safest to riskiest and the fraction of observed total cumulated claims is plotted on the y axis. This plot is often called the ordered Lorenz curve of the model.

The Gini coefficient (based on the area under the curve) can be used as a model selection metric to quantify the ability of the model to rank policyholders. Note that this metric does not reflect the ability of the models to make accurate predictions in terms of absolute value of total claim amounts but only in terms of relative amounts as a ranking metric.

Both models are able to rank policyholders by risky-ness significantly better than chance although they are also both far from perfect due to the natural difficulty of the prediction problem from few features.

Note that the Gini index only characterize the ranking performance of the model but not its calibration: any monotonic transformation of the predictions leaves the Gini index of the model unchanged.

Finally one should highlight that the Compound Poisson Gamma model that is directly fit on the pure premium is operationally simpler to develop and maintain as it consists in a single scikit-learn estimator instead of a pair of models, each with its own set of hyperparameters.

```python
def lorenz_curve(y_true, y_pred, exposure):
    y_true, y_pred = np.asarray(y_true), np.asarray(y_pred)
    exposure = np.asarray(exposure)

    # order samples by increasing predicted risk:
    ranking = np.argsort(y_pred)
    ranked_exposure = exposure[ranking]
    ranked_pure_premium = y_true[ranking]
    cumulated_claim_amount = np.cumsum(ranked_pure_premium * ranked_exposure)
    cumulated_claim_amount /= cumulated_claim_amount[-1]
    cumulated_samples = np.linspace(0, 1, len(cumulated_claim_amount))
    return cumulated_samples, cumulated_claim_amount
```

fig, ax = plt.subplots(figsize=(8, 8))

y_pred_product = glm_freq.predict(X_test) * glm_sev.predict(X_test)
y_pred_total = glm_pure_premium.predict(X_test)

for label, y_pred in ["Frequency * Severity model", y_pred_product],
    ("Compound Poisson Gamma", y_pred_total):
    ordered_samples, cum_claims = lorenz_curve(
        df_test["PurePremium"], y_pred, df_test["Exposure"]
    )
gini = 1 - 2 * auc(ordered_samples, cum_claims)
label += " (Gini index: {:.3f})".format(gini)
ax.plot(ordered_samples, cum_claims, linestyle="--", label=label)
# Oracle model: y_pred == y_test
ordered_samples, cum_claims = lorenz_curve(
    df_test["PurePremium"], df_test["PurePremium"], df_test["Exposure"])
gini = 1 - 2 * auc(ordered_samples, cum_claims)
label = "Oracle (Gini index: {:.3f})".format(gini)
ax.plot(ordered_samples, cum_claims, linestyle="-.", color="gray",
    label=label)

6.17. Generalized Linear Models
6.18 Inspection

Examples related to the `sklearn.inspection` module.

6.18.1 Permutation Importance with Multicollinear or Correlated Features

In this example, we compute the permutation importance on the Wisconsin breast cancer dataset using `permutation_importance`. The `RandomForestClassifier` can easily get about 97% accuracy on a test dataset. Because this dataset contains multicollinear features, the permutation importance will show that none of the features are important. One approach to handling multicollinearity is by performing hierarchical clustering on the features' Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster.

**Note:** See also *Permutation Importance vs Random Forest Feature Importance (MDI)*

```python
print(__doc__)
from collections import defaultdict
import matplotlib.pyplot as plt
import numpy as np
from scipy.stats import spearmanr
from scipy.cluster import hierarchy
from sklearn.datasets import load_breast_cancer
from sklearn.ensemble import RandomForestClassifier
from sklearn.inspection import permutation_importance
from sklearn.model_selection import train_test_split
```

Random Forest Feature Importance on Breast Cancer Data

First, we train a random forest on the breast cancer dataset and evaluate its accuracy on a test set:

```python
data = load_breast_cancer()
X, y = data.data, data.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)
clf = RandomForestClassifier(n_estimators=100, random_state=42)
clf.fit(X_train, y_train)
print("Accuracy on test data: {:.2f}".format(clf.score(X_test, y_test)))
```

Out:

```
Accuracy on test data: 0.97
```

Next, we plot the tree based feature importance and the permutation importance. The permutation importance plot shows that permuting a feature drops the accuracy by at most 0.012, which would suggest that none of the features are important. This is in contradiction with the high test accuracy computed above: some feature must be important. The permutation importance is calculated on the training set to show how much the model relies on each feature during training.

```python
result = permutation_importance(clf, X_train, y_train, n_repeats=10, random_state=42)
perm_sorted_idx = result.importances_mean.argsort()
```

(continues on next page)
```python
tree_importance_sorted_idx = np.argsort(clf.feature_importances_
tree_indices = np.arange(0, len(clf.feature_importances_)) + 0.5

fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
ax1.barh(tree_indices,
    clf.feature_importances_[tree_importance_sorted_idx], height=0.7)
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
ax1.set_yticks(tree_indices)
ax1.set_ylim((0, len(clf.feature_importances_)))
ax2.boxplot(result.importances[perm_sorted_idx].T, vert=False,
    labels=data.feature_names[perm_sorted_idx])
fig.tight_layout()
plt.show()
```

Out:

```
/home/circleci/project/examples/inspection/plot_permutation_importance_multicollinear.
---py:63: UserWarning: FixedFormatter should only be used together with FixedLocator
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
```
Handling Multicollinear Features

When features are collinear, permutating one feature will have little effect on the models performance because it can get the same information from a correlated feature. One way to handle multicollinear features is by performing hierarchical clustering on the Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster. First, we plot a heatmap of the correlated features:

```python
fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
corr = spearmanr(X).correlation
corr_linkage = hierarchy.ward(corr)
dendro = hierarchy.dendrogram(
    corr_linkage, labels=data.feature_names.tolist(), ax=ax1, leaf_rotation=90
)
dendro_idx = np.arange(0, len(dendro['ivl']))

ax2.imshow(corr[dendro['leaves'], :][:, dendro['leaves']])
ax2.set_xticks(dendro_idx)
ax2.set_yticks(dendro_idx)
ax2.set_xticklabels(dendro['ivl'], rotation='vertical')
ax2.set_yticklabels(dendro['ivl'])
fig.tight_layout()
plt.show()
```

Next, we manually pick a threshold by visual inspection of the dendrogram to group our features into clusters and choose a feature from each cluster to keep, select those features from our dataset, and train a new random forest. The test accuracy of the new random forest did not change much compared to the random forest trained on the complete dataset.
cluster_ids = hierarchy.fcluster(corr_linkage, 1, criterion='distance')
cluster_id_to_feature_ids = defaultdict(list)
for idx, cluster_id in enumerate(cluster_ids):
    cluster_id_to_feature_ids[cluster_id].append(idx)
selected_features = [v[0] for v in cluster_id_to_feature_ids.values()]
X_train_sel = X_train[:, selected_features]
X_test_sel = X_test[:, selected_features]
clf_sel = RandomForestClassifier(n_estimators=100, random_state=42)
clf_sel.fit(X_train_sel, y_train)
print("Accuracy on test data with features removed: {:.2f}".format(
    clf_sel.score(X_test_sel, y_test)))

Out:
Accuracy on test data with features removed: 0.97

Total running time of the script: ( 0 minutes 5.221 seconds)

6.18.2 Permutation Importance vs Random Forest Feature Importance (MDI)

In this example, we will compare the impurity-based feature importance of RandomForestClassifier with the permutation importance on the titanic dataset using permutation_importance. We will show that the impurity-based feature importance can inflate the importance of numerical features.

Furthermore, the impurity-based feature importance of random forests suffers from being computed on statistics derived from the training dataset: the importances can be high even for features that are not predictive of the target variable, as long as the model has the capacity to use them to overfit.

This example shows how to use Permutation Importances as an alternative that can mitigate those limitations.

References:

print(__doc__)
import matplotlib.pyplot as plt
import numpy as np

6.18. Inspection
Data Loading and Feature Engineering

Let’s use pandas to load a copy of the titanic dataset. The following shows how to apply separate preprocessing on numerical and categorical features.

We further include two random variables that are not correlated in any way with the target variable (survived):

- random_num is a high cardinality numerical variable (as many unique values as records).
- random_cat is a low cardinality categorical variable (3 possible values).

```python
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)
rng = np.random.RandomState(seed=42)
X['random_cat'] = rng.randint(3, size=X.shape[0])
X['random_num'] = rng.randn(X.shape[0])

categorical_columns = ['pclass', 'sex', 'embarked', 'random_cat']
umerical_columns = ['age', 'sibsp', 'parch', 'fare', 'random_num']

X = X[categorical_columns + numerical_columns]

X_train, X_test, y_train, y_test = train_test_split(
    X, y, stratify=y, random_state=42)
categorical_encoder = OneHotEncoder(handle_unknown='ignore')
umerical_pipe = Pipeline([
    ('imputer', SimpleImputer(strategy='mean'))])

preprocessing = ColumnTransformer(
    [('cat', categorical_encoder, categorical_columns),
     ('num', numerical_pipe, numerical_columns)])

rf = Pipeline([
    ('preprocess', preprocessing),
    ('classifier', RandomForestClassifier(random_state=42))])

rf.fit(X_train, y_train)
```

Accuracy of the Model

Prior to inspecting the feature importances, it is important to check that the model predictive performance is high enough. Indeed there would be little interest of inspecting the important features of a non-predictive model.

Here one can observe that the train accuracy is very high (the forest model has enough capacity to completely memorize the training set) but it can still generalize well enough to the test set thanks to the built-in bagging of random forests.

It might be possible to trade some accuracy on the training set for a slightly better accuracy on the test set by limiting the capacity of the trees (for instance by setting `min_samples_leaf=5` or `min_samples_leaf=10`) so as to limit overfitting while not introducing too much underfitting.

However let’s keep our high capacity random forest model for now so as to illustrate some pitfalls with feature importance on variables with many unique values.

```python
print("RF train accuracy: %0.3f" % rf.score(X_train, y_train))
print("RF test accuracy: %0.3f" % rf.score(X_test, y_test))
```

Out:
RF train accuracy: 1.000
RF test accuracy: 0.817

Tree's Feature Importance from Mean Decrease in Impurity (MDI)

The impurity-based feature importance ranks the numerical features to be the most important features. As a result, the non-predictive `random_num` variable is ranked the most important!

This problem stems from two limitations of impurity-based feature importances:

- impurity-based importances are biased towards high cardinality features;
- impurity-based importances are computed on training set statistics and therefore do not reflect the ability of feature to be useful to make predictions that generalize to the test set (when the model has enough capacity).

```python
ohe = (rf.named_steps['preprocess']
    .named_transformers_['cat'])
feature_names = ohe.get_feature_names(input_features=categorical_columns)
feature_names = np.r_[feature_names, numerical_columns]

tree_feature_importances = (    rf.named_steps['classifier'].feature_importances_)
sorted_idx = tree_feature_importances.argsort()

y_ticks = np.arange(0, len(feature_names))
fig, ax = plt.subplots()
ax.barh(y_ticks, tree_feature_importances[sorted_idx])
ax.set_yticklabels(feature_names[sorted_idx])
ax.set_yticks(y_ticks)
ax.set_title("Random Forest Feature Importances (MDI)")
fig.tight_layout()
plt.show()
```
As an alternative, the permutation importances of rf are computed on a held out test set. This shows that the low cardinality categorical feature, sex is the most important feature.

Also note that both random features have very low importances (close to 0) as expected.
It is also possible to compute the permutation importances on the training set. This reveals that `random_num` gets a significantly higher importance ranking than when computed on the test set. The difference between those two plots is a confirmation that the RF model has enough capacity to use that random numerical feature to overfit. You can further confirm this by re-running this example with constrained RF with `min_samples_leaf=10`.

```python
result = permutation_importance(rf, X_train, y_train, n_repeats=10,
                                random_state=42, n_jobs=2)
sorted_idx = result.importances_mean.argsort()

fig, ax = plt.subplots()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=X_train.columns[sorted_idx])
ax.set_title("Permutation Importances (train set)")
fig.tight_layout()
plt.show()
```
Partial dependence plots show the dependence between the target function and a set of features of interest, marginalizing over the values of all other features (the complement features). Due to the limits of human perception, the size of the set of features of interest must be small (usually, one or two) thus they are usually chosen among the most important features.

Similarly, an individual conditional expectation (ICE) plot shows the dependence between the target function and a feature of interest. However, unlike partial dependence plots, which show the average effect of the features of interest, ICE plots visualize the dependence of the prediction on a feature for each sample separately, with one line per sample. Only one feature of interest is supported for ICE plots.

This example shows how to obtain partial dependence and ICE plots from a MLPRegressor and a HistGradientBoostingRegressor trained on the California housing dataset. The example is taken from 1.

\footnote{For classification you can think of it as the regression score before the link function.}

California Housing data preprocessing

Center target to avoid gradient boosting init bias: gradient boosting with the ‘recursion’ method does not account for the initial estimator (here the average target, by default).

```python
import pandas as pd
from sklearn.datasets import fetch_california_housing
from sklearn.model_selection import train_test_split

cal_housing = fetch_california_housing()
X = pd.DataFrame(cal_housing.data, columns=cal_housing.feature_names)
y = cal_housing.target

y -= y.mean()

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.1, random_state=0)
```

1-way partial dependence with different models

In this section, we will compute 1-way partial dependence with two different machine-learning models: (i) a multi-layer perceptron and (ii) a gradient-boosting. With these two models, we illustrate how to compute and interpret both partial dependence plot (PDP) and individual conditional expectation (ICE).

Multi-layer perceptron

Let’s fit a `MLPRegressor` and compute single-variable partial dependence plots.

```python
from time import time
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import QuantileTransformer
from sklearn.neural_network import MLPRegressor

print("Training MLPRegressor...")
tic = time()
est = make_pipeline(QuantileTransformer(),
                      MLPRegressor(hidden_layer_sizes=(50, 50),
                                    learning_rate_init=0.01,
                                    early_stopping=True))
est.fit(X_train, y_train)
print(f"done in {time() - tic:.3f}s")
print(f"Test R2 score: {est.score(X_test, y_test):.2f}/")
```

Out:

```
Training MLPRegressor...
done in 3.703s
Test R2 score: 0.81
```

We configured a pipeline to scale the numerical input features and tuned the neural network size and learning rate to get a reasonable compromise between training time and predictive performance on a test set.

Importantly, this tabular dataset has very different dynamic ranges for its features. Neural networks tend to be very sensitive to features with varying scales and forgetting to preprocess the numeric feature would lead to a very poor model.
It would be possible to get even higher predictive performance with a larger neural network but the training would also be significantly more expensive.

Note that it is important to check that the model is accurate enough on a test set before plotting the partial dependence since there would be little use in explaining the impact of a given feature on the prediction function of a poor model.

We will plot the partial dependence, both individual (ICE) and averaged one (PDP). We limit to only 50 ICE curves to not overcrowd the plot.

```python
import matplotlib.pyplot as plt
from sklearn.inspection import partial_dependence
from sklearn.inspection import plot_partial_dependence

print('Computing partial dependence plots...')
tic = time()
features = ['MedInc', 'AveOccup', 'HouseAge', 'AveRooms']
display = plot_partial_dependence(
    est, X_train, features, kind="both", subsample=50,
    n_jobs=3, grid_resolution=20
)
print(f"done in {time() - tic:.3f}s")
display.figure_.suptitle("Partial dependence of house value on non-location features for the California housing dataset, with MLPRegressor")
display.figure_.subplots_adjust(hspace=0.3)
```

Partial dependence of house value on non-location features for the California housing dataset, with MLPRegressor
Gradient boosting

Let's now fit a `HistGradientBoostingRegressor` and compute the partial dependence on the same features.

```python
from sklearn.experimental import enable_hist_gradient_boosting
from sklearn.ensemble import HistGradientBoostingRegressor

print("Training HistGradientBoostingRegressor...")
tic = time()
est = HistGradientBoostingRegressor()
est.fit(X_train, y_train)
print(f"done in {tic:.3f}s")

print(f"Test R2 score: {est.score(X_test, y_test):.2f}"
```

Here, we used the default hyperparameters for the gradient boosting model without any preprocessing as tree-based models are naturally robust to monotonic transformations of numerical features.

Note that on this tabular dataset, Gradient Boosting Machines are both significantly faster to train and more accurate than neural networks. It is also significantly cheaper to tune their hyperparameters (the defaults tend to work well while this is not often the case for neural networks).

We will plot the partial dependence, both individual (ICE) and averaged one (PDP). We limit to only 50 ICE curves to not overcrowd the plot.

```python
print('Computing partial dependence plots...')
tic = time()
display = plot_partial_dependence(est, X_train, features, kind="both", subsample=50,
    n_jobs=3, grid_resolution=20)
print(f"done in {tic:.3f}s")
display.figure_.suptitle(
    'Partial dependence of house value on non-location features
    for the California housing dataset, with Gradient Boosting'
)
display.figure_.subplots_adjust(wspace=0.4, hspace=0.3)
```
Computing partial dependence plots...
done in 2.810s

Analysis of the plots

We can clearly see on the PDPs (thick blue line) that the median house price shows a linear relationship with the median income (top left) and that the house price drops when the average occupants per household increases (top middle). The top right plot shows that the house age in a district does not have a strong influence on the (median) house price; so does the average rooms per household.

The ICE curves (light blue lines) complement the analysis: we can see that there are some exceptions, where the house price remain constant with median income and average occupants. On the other hand, while the house age (top right) does not have a strong influence on the median house price on average, there seems to be a number of exceptions where the house price increase when between the ages 15-25. Similar exceptions can be observed for the average number of rooms (bottom left). Therefore, ICE plots show some individual effect which are attenuated by taking the averages.

In all plots, the tick marks on the x-axis represent the deciles of the feature values in the training data.

We also observe that `MLPRegressor` has much smoother predictions than `HistGradientBoostingRegressor`.

However, it is worth noting that we are creating potential meaningless synthetic samples if features are correlated.
2D interaction plots

PDPs with two features of interest enable us to visualize interactions among them. However, ICEs cannot be plotted in an easy manner and thus interpreted. Another consideration is linked to the performance to compute the PDPs. With the tree-based algorithm, when only PDPs are requested, they can be computed on an efficient way using the 'recursion' method.

```python
features = ['AveOccup', 'HouseAge', ('AveOccup', 'HouseAge')]
print('Computing partial dependence plots...')
tic = time()
_, ax = plt.subplots(ncols=3, figsize=(9, 4))
display = plot_partial_dependence(
    est, X_train, features, kind='average', n_jobs=3, grid_resolution=20,
    ax=ax,
)
print(f"done in \{tic:.3f\}s")
display.figure_.suptitle("Partial dependence of house value on non-location features\nfor the California housing dataset, with Gradient Boosting")
display.figure_.subplots_adjust(wspace=0.4, hspace=0.3)
```

The two-way partial dependence plot shows the dependence of median house price on joint values of house age and average occupants per household. We can clearly see an interaction between the two features: for an average occupancy greater than two, the house price is nearly independent of the house age, whereas for values less than two there is a strong dependence on age.
3D interaction plots

Let’s make the same partial dependence plot for the 2 features interaction, this time in 3 dimensions.

```python
import numpy as np
from mpl_toolkits.mplot3d import Axes3D
fig = plt.figure()

features = ('AveOccup', 'HouseAge')
pdp = partial_dependence(
    est, X_train, features=features, kind='average', grid_resolution=20
)
XX, YY = np.meshgrid(pdp['values'][0], pdp['values'][1])
Z = pdp.average[0].T
ax = Axes3D(fig)
surf = ax.plot_surface(XX, YY, Z, rstride=1, cstride=1,
    cmap=plt.cm.BuPu, edgecolor='k')
ax.set_xlabel(features[0])
ax.set_ylabel(features[1])
ax.set_zlabel('Partial dependence')
# pretty init view
ax.view_init(elev=22, azim=122)
plt.colorbar(surf)
plt.suptitle('Partial dependence of house value on median

age and average occupancy, with Gradient Boosting')
plt.subplots_adjust(top=0.9)
plt.show()
```
In linear models, the target value is modeled as a linear combination of the features (see the *Linear Models* User Guide section for a description of a set of linear models available in scikit-learn). Coefficients in multiple linear models represent the relationship between the given feature, $X_i$, and the target, $y$, assuming that all the other features remain constant (conditional dependence). This is different from plotting $X_i$ versus $y$ and fitting a linear relationship: in that case all possible values of the other features are taken into account in the estimation (marginal dependence).

This example will provide some hints in interpreting coefficient in linear models, pointing at problems that arise when either the linear model is not appropriate to describe the dataset, or when features are correlated.

We will use data from the “Current Population Survey” from 1985 to predict wage as a function of various features such as experience, age, or education.
The problem of correlated variables
Preprocessing numerical variables
Linear models with regularization
Linear models with sparse coefficients
Lessons learned

The dataset: wages

We fetch the data from OpenML. Note that setting the parameter as_frame to True will retrieve the data as a pandas dataframe.

```python
from sklearn.datasets import fetch_openml
survey = fetch_openml(data_id=534, as_frame=True)
```

Then, we identify features \( X \) and targets \( y \): the column WAGE is our target variable (i.e., the variable which we want to predict).

```python
X = survey.data[survey.feature_names]
X.describe(include="all")
```

Note that the dataset contains categorical and numerical variables. We will need to take this into account when preprocessing the dataset thereafter.

```python
X.head()
```

Our target for prediction: the wage. Wages are described as floating-point number in dollars per hour.

```python
y = survey.target.values.ravel()
survey.target.head()
```

Out:

```
0  5.10
1  4.95
2  6.67
3  4.00
4  7.50
Name: WAGE, dtype: float64
```

We split the sample into a train and a test dataset. Only the train dataset will be used in the following exploratory analysis. This is a way to emulate a real situation where predictions are performed on an unknown target, and we don’t want our analysis and decisions to be biased by our knowledge of the test data.
First, let's get some insights by looking at the variable distributions and at the pairwise relationships between them. Only numerical variables will be used. In the following plot, each dot represents a sample.
Looking closely at the WAGE distribution reveals that it has a long tail. For this reason, we should take its logarithm to turn it approximately into a normal distribution (linear models such as ridge or lasso work best for a normal distribution of error).

The WAGE is increasing when EDUCATION is increasing. Note that the dependence between WAGE and EDUCATION represented here is a marginal dependence, i.e., it describes the behavior of a specific variable without keeping the others fixed.

Also, the EXPERIENCE and AGE are strongly linearly correlated.

The machine-learning pipeline

To design our machine-learning pipeline, we first manually check the type of data that we are dealing with:

```python
survey.data.info()
```

Out:

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 534 entries, 0 to 533
Data columns (total 10 columns):
  #   Column      Non-Null Count  Dtype
  ---  --------    --------------  -----  
  0   EDUCATION   534 non-null    float64
  1   SOUTH       534 non-null    category
  2   SEX         534 non-null    category
  3   EXPERIENCE  534 non-null    float64
  4   UNION       534 non-null    category
  5   AGE         534 non-null    float64
  6   RACE        534 non-null    category
  7   OCCUPATION  534 non-null    category
  8   SECTOR      534 non-null    category
  9   MARR        534 non-null    category
dtypes: category(7), float64(3)
memory usage: 17.1 KB
```

As seen previously, the dataset contains columns with different data types and we need to apply a specific preprocessing for each data type. In particular categorical variables cannot be included in linear model if not coded as integers first. In addition, to avoid categorical features to be treated as ordered values, we need to one-hot-encode them. Our preprocessor will

- one-hot encode (i.e., generate a column by category) the categorical columns;
- as a first approach (we will see after how the normalisation of numerical values will affect our discussion), keep numerical values as they are.

```python
from sklearn.compose import make_column_transformer
from sklearn.preprocessing import OneHotEncoder

categorical_columns = ['RACE', 'OCCUPATION', 'SECTOR',
                       'MARR', 'UNION', 'SEX', 'SOUTH']
numerical_columns = ['EDUCATION', 'EXPERIENCE', 'AGE']

preprocessor = make_column_transformer(
    (OneHotEncoder(drop='if_binary'), categorical_columns),
    remainder='passthrough'
)
```
scikit-learn user guide, Release 0.24.dev0

To describe the dataset as a linear model we use a ridge regressor with a very small regularization and to model the
logarithm of the WAGE.
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import Ridge
from sklearn.compose import TransformedTargetRegressor
model = make_pipeline(
preprocessor,
TransformedTargetRegressor(
regressor=Ridge(alpha=1e-10),
func=np.log10,
inverse_func=sp.special.exp10
)
)

Processing the dataset
First, we fit the model.
_ = model.fit(X_train, y_train)

Then we check the performance of the computed model plotting its predictions on the test set and computing, for
example, the median absolute error of the model.
from sklearn.metrics import median_absolute_error
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'MAE on training set: {mae:.2f} $/hour'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'\nMAE on testing set: {mae:.2f} $/hour'
fig, ax = plt.subplots(figsize=(5, 5))
plt.scatter(y_test, y_pred)
ax.plot([0, 1], [0, 1], transform=ax.transAxes, ls="--", c="red")
plt.text(3, 20, string_score)
plt.title('Ridge model, small regularization')
plt.ylabel('Model predictions')
plt.xlabel('Truths')
plt.xlim([0, 27])
_ = plt.ylim([0, 27])

6.18. Inspection

1273


The model learnt is far from being a good model making accurate predictions: this is obvious when looking at the plot above, where good predictions should lie on the red line.

In the following section, we will interpret the coefficients of the model. While we do so, we should keep in mind that any conclusion we draw is about the model that we build, rather than about the true (real-world) generative process of the data.

**Interpreting coefficients: scale matters**

First of all, we can take a look to the values of the coefficients of the regressor we have fitted.

```python
feature_names = (model.named_steps['columntransformer']
    .named_transformers_['onehotencoder']
    .get_feature_names(input_features=categorical_columns))
feature_names = np.concatenate([feature_names, numerical_columns])
coefs = pd.DataFrame(model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names)
coefs
```
The \( \text{AGE} \) coefficient is expressed in “dollars/hour per living years” while the \( \text{EDUCATION} \) one is expressed in “dollars/hour per years of education”. This representation of the coefficients has the benefit of making clear the practical predictions of the model: an increase of 1 year in \( \text{AGE} \) means a decrease of 0.030867 dollars/hour, while an increase of 1 year in \( \text{EDUCATION} \) means an increase of 0.054699 dollars/hour. On the other hand, categorical variables (as \( \text{UNION} \) or \( \text{SEX} \)) are adimensional numbers taking either the value 0 or 1. Their coefficients are expressed in dollars/hour. Then, we cannot compare the magnitude of different coefficients since the features have different natural scales, and hence value ranges, because of their different unit of measure. This is more visible if we plot the coefficients.

Indeed, from the plot above the most important factor in determining \( \text{WAGE} \) appears to be the variable \( \text{UNION} \), even if our intuition might tell us that variables like \( \text{EXPERIENCE} \) should have more impact.

Looking at the coefficient plot to gauge feature importance can be misleading as some of them vary on a small scale, while others, like \( \text{AGE} \), varies a lot more, several decades.

This is visible if we compare the standard deviations of different features.

```python
X_train_preprocessed = pd.DataFrame(  
    model.named_steps['columntransformer'].transform(X_train),  
)(continues on next page)"
Multiplying the coefficients by the standard deviation of the related feature would reduce all the coefficients to the same unit of measure. As we will see after this is equivalent to normalize numerical variables to their standard deviation, as \( y = \sum coef_i \times X_i = \sum (coef_i \times std_i) \times (X_i/\text{std}_i) \).

In that way, we emphasize that the greater the variance of a feature, the larger the weight of the corresponding coefficient on the output, all else being equal.
Now that the coefficients have been scaled, we can safely compare them.

**Warning:** Why does the plot above suggest that an increase in age leads to a decrease in wage? Why the *initial* pairplot is telling the opposite?

The plot above tells us about dependencies between a specific feature and the target when all other features remain constant, i.e., conditional dependencies. An increase of the AGE will induce a decrease of the WAGE when all other features remain constant. On the contrary, an increase of the EXPERIENCE will induce an increase of the WAGE when all other features remain constant. Also, AGE, EXPERIENCE and EDUCATION are the three variables that most influence the model.
Checking the variability of the coefficients

We can check the coefficient variability through cross-validation: it is a form of data perturbation (related to resampling).

If coefficients vary significantly when changing the input dataset their robustness is not guaranteed, and they should probably be interpreted with caution.

```python
from sklearn.model_selection import cross_validate
from sklearn.model_selection import RepeatedKFold

cv_model = cross_validate(
    model, X, y, cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)
coefs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_ *
     X_train_preprocessed.std(axis=0)
     for est in cv_model['estimator']],
    columns=feature_names
)
plt.figure(figsize=(9, 7))
sns.swarmplot(data=coefs, orient='h', color='k', alpha=0.5)
sns.boxplot(data=coefs, orient='h', color='cyan', saturation=0.5)
plt.axvline(x=0, color='.5')
plt.xlabel('Coefficient importance')
plt.title('Coefficient importance and its variability')
plt.subplots_adjust(left=.3)
```

(continues on next page)
The problem of correlated variables

The AGE and EXPERIENCE coefficients are affected by strong variability which might be due to the collinearity between the 2 features: as AGE and EXPERIENCE vary together in the data, their effect is difficult to tease apart.

To verify this interpretation we plot the variability of the AGE and EXPERIENCE coefficient.

```python
plt.ylabel('Age coefficient')
plt.xlabel('Experience coefficient')
plt.grid(True)
plt.xlim(-0.4, 0.5)
plt.ylim(-0.4, 0.5)
plt.scatter(coefs['AGE'], coefs['EXPERIENCE'])
plt.title('Co-variations of coefficients for AGE and EXPERIENCE across folds')
```
Two regions are populated: when the EXPERIENCE coefficient is positive the AGE one is negative and vice versa.

To go further we remove one of the 2 features and check what is the impact on the model stability.

column_to_drop = ['AGE']

cv_model = cross_validate(
    model, X.drop(columns=column_to_drop), y,
    cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=False, n_jobs=-1
)

coeffs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_ *
     X_train_preprocessed.drop(columns=column_to_drop).std(axis=0)
    for est in cv_model['estimator']],
    columns=feature_names[:-1]
)

plt.figure(figsize=(9, 7))
sns.swarmplot(data=coeffs, orient='h', color='k', alpha=0.5)
sns.boxplot(data=coeffs, orient='h', color='cyan', saturation=0.5)
plt.axvline(x=0, color='.5')
plt.title('Coefficient importance and its variability')
plt.xlabel('Coefficient importance')
plt.subplots_adjust(left=.3)

The estimation of the EXPERIENCE coefficient is now less variable and remain important for all models trained
during cross-validation.
Preprocessing numerical variables
As said above (see “The machine-learning pipeline”), we could also choose to scale numerical values before training
the model. This can be useful to apply a similar amount regularization to all of them in the Ridge. The preprocessor is
redefined in order to subtract the mean and scale variables to unit variance.
from sklearn.preprocessing import StandardScaler
preprocessor = make_column_transformer(
(OneHotEncoder(drop='if_binary'), categorical_columns),
(StandardScaler(), numerical_columns),
remainder='passthrough'
)

The model will stay unchanged.
model = make_pipeline(
preprocessor,
TransformedTargetRegressor(
regressor=Ridge(alpha=1e-10),
func=np.log10,
inverse_func=sp.special.exp10
)
)
_ = model.fit(X_train, y_train)

Again, we check the performance of the computed model using, for example, the median absolute error of the model
and the R squared coefficient.
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'MAE on training set: {mae:.2f} $/hour'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'\nMAE on testing set: {mae:.2f} $/hour'
fig, ax = plt.subplots(figsize=(6, 6))
plt.scatter(y_test, y_pred)
ax.plot([0, 1], [0, 1], transform=ax.transAxes, ls="--", c="red")
plt.text(3, 20, string_score)
(continues on next page)

6.18. Inspection

1283


For the coefficient analysis, scaling is not needed this time.

```python
coeffs = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names
)
coeffs.plot(kind='barh', figsize=(9, 7))
coeffs.plot(kind='barh', figsize=(9, 7))
```
We now inspect the coefficients across several cross-validation folds.

```python
cv_model = cross_validate(
    model, X, y, cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)
coefs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_
        for est in cv_model['estimator']],
    columns=feature_names
)
plt.figure(figsize=(9, 7))
sns.swarmplot(data=coefs, orient='h', color='k', alpha=0.5)
sns.boxplot(data=coefs, orient='h', color='cyan', saturation=0.5)
plt.axvline(x=0, color='.5')
plt.title('Coefficient variability')
plt.subplots_adjust(left=.3)
```

  warnings.warn(msg, UserWarning)
The result is quite similar to the non-normalized case.

**Linear models with regularization**

In machine-learning practice, Ridge Regression is more often used with non-negligible regularization.

Above, we limited this regularization to a very little amount. Regularization improves the conditioning of the problem and reduces the variance of the estimates. RidgeCV applies cross validation in order to determine which value of the regularization parameter (alpha) is best suited for prediction.

```python
from sklearn.linear_model import RidgeCV

model = make_pipeline(  
    preprocessor,  
    TransformedTargetRegressor(  
        regressor=RidgeCV(alphas=np.logspace(-10, 10, 21)),  
        func=np.log10,  
        inverse_func=sp.special.exp10  
    )  
)

_ = model.fit(X_train, y_train)
```

First we check which value of $\alpha$ has been selected.

```python
model[-1].regressor_.alpha_
```

Out:

```
10.0
```

Then we check the quality of the predictions.

```python
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'\nMAE on training set: {mae:.2f} \$/hour'

y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'\nMAE on testing set: {mae:.2f} \$/hour'
```

(continues on next page)
The ability to reproduce the data of the regularized model is similar to the one of the non-regularized model.

```python
coefs = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names
)
The coefficients are significantly different. AGE and EXPERIENCE coefficients are both positive but they now have less influence on the prediction.

The regularization reduces the influence of correlated variables on the model because the weight is shared between the two predictive variables, so neither alone would have strong weights.

On the other hand, the weights obtained with regularization are more stable (see the Ridge regression and classification User Guide section). This increased stability is visible from the plot, obtained from data perturbations, in a cross validation. This plot can be compared with the previous one.

```
cv_model = cross_validate(
    model, X, y, cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)
coefs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_ *
     X_train_preprocessed.std(axis=0)
    for est in cv_model['estimator'])
```
for est in cv_model['estimator']
    columns=feature_names
)

plt.ylabel('Age coefficient')
plt.xlabel('Experience coefficient')
plt.grid(True)
plt.xlim(-0.4, 0.5)
plt.ylim(-0.4, 0.5)
plt.scatter(coefs['AGE'], coefs['EXPERIENCE'])
_ = plt.title('Co-variations of coefficients for AGE and EXPERIENCE ' 'across folds')

Linear models with sparse coefficients

Another possibility to take into account correlated variables in the dataset, is to estimate sparse coefficients. In some way we already did it manually when we dropped the AGE column in a previous Ridge estimation.

Lasso models (see the Lasso User Guide section) estimates sparse coefficients. LassoCV applies cross validation in order to determine which value of the regularization parameter (alpha) is best suited for the model estimation.

from sklearn.linear_model import LassoCV

(continues on next page)
scikit-learn user guide, Release 0.24.dev0

(continued from previous page)

model = make_pipeline(
preprocessor,
TransformedTargetRegressor(
regressor=LassoCV(alphas=np.logspace(-10, 10, 21), max_iter=100000),
func=np.log10,
inverse_func=sp.special.exp10
)
)
_ = model.fit(X_train, y_train)

First we verify which value of 𝛼 has been selected.
model[-1].regressor_.alpha_

Out:
0.001

Then we check the quality of the predictions.
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'MAE on training set: {mae:.2f} $/hour'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'\nMAE on testing set: {mae:.2f} $/hour'
fig, ax = plt.subplots(figsize=(6, 6))
plt.scatter(y_test, y_pred)
ax.plot([0, 1], [0, 1], transform=ax.transAxes, ls="--", c="red")
plt.text(3, 20, string_score)
plt.title('Lasso model, regularization, normalized variables')
plt.ylabel('Model predictions')
plt.xlabel('Truths')
plt.xlim([0, 27])
_ = plt.ylim([0, 27])

6.18. Inspection

1291


For our dataset, again the model is not very predictive.

```python
coops = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names
)
coops.plot(kind='barh', figsize=(9, 7))
plt.title('Lasso model, regularization, normalized variables')
plt.axvline(x=0, color='.5')
plt.subplots_adjust(left=.3)
```
A Lasso model identifies the correlation between AGE and EXPERIENCE and suppresses one of them for the sake of the prediction.

It is important to keep in mind that the coefficients that have been dropped may still be related to the outcome by themselves: the model chose to suppress them because they bring little or no additional information on top of the other features. Additionnaly, this selection is unstable for correlated features, and should be interpreted with caution.

**Lessons learned**

- Coefficients must be scaled to the same unit of measure to retrieve feature importance. Scaling them with the standard-deviation of the feature is a useful proxy.

- Coefficients in multivariate linear models represent the dependency between a given feature and the target, **conditional** on the other features.

- Correlated features induce instabilities in the coefficients of linear models and their effects cannot be well teased apart.

- Different linear models respond differently to feature correlation and coefficients could significantly vary from one another.

- Inspecting coefficients across the folds of a cross-validation loop gives an idea of their stability.

6.19.4 t-SNE: The effect of various perplexity values on the shape

An illustration of t-SNE on the two concentric circles and the S-curve datasets for different perplexity values.

We observe a tendency towards clearer shapes as the perplexity value increases.

The size, the distance and the shape of clusters may vary upon initialization, perplexity values and does not always convey a meaning.

As shown below, t-SNE for higher perplexities finds meaningful topology of two concentric circles, however the size and the distance of the circles varies slightly from the original. Contrary to the two circles dataset, the shapes visually diverge from S-curve topology on the S-curve dataset even for larger perplexity values.

For further details, “How to Use t-SNE Effectively” https://distill.pub/2016/misread-tsne/ provides a good discussion of the effects of various parameters, as well as interactive plots to explore those effects.

### 6.19.5 Manifold Learning methods on a severed sphere

An application of the different *Manifold learning* techniques on a spherical data-set. Here one can see the use of dimensionality reduction in order to gain some intuition regarding the manifold learning methods. Regarding the dataset, the poles are cut from the sphere, as well as a thin slice down its side. This enables the manifold learning techniques to ‘spread it open’ whilst projecting it onto two dimensions.

For a similar example, where the methods are applied to the S-curve dataset, see *Comparison of Manifold Learning methods*

Note that the purpose of the *MDS* is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seek an isotropic representation of the data in the low-dimensional space. Here the manifold problem matches fairly that of representing a flat map of the Earth, as with *map projection*.

```python
Manifold Learning with 1000 points, 10 neighbors
```

6.19.6 Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

An illustration of various embeddings on the digits dataset.

The RandomTreesEmbedding, from the sklearn.ensemble module, is not technically a manifold embedding method, as it learn a high-dimensional representation on which we apply a dimensionality reduction method. However, it is often useful to cast a dataset into a representation in which the classes are linearly-separable.

t-SNE will be initialized with the embedding that is generated by PCA in this example, which is not the default setting. It ensures global stability of the embedding, i.e., the embedding does not depend on random initialization.

Linear Discriminant Analysis, from the sklearn.discriminant_analysis module, and Neighborhood Components Analysis, from the sklearn.neighbors module, are supervised dimensionality reduction method, i.e. they make use of the provided labels, contrary to other methods.
A selection from the 64-dimensional digits dataset

6.20 Miscellaneous

Miscellaneous and introductory examples for scikit-learn.

6.20.1 Compact estimator representations

This example illustrates the use of the print_changed_only global parameter.

Setting print_changed_only to True will alternate the representation of estimators to only show the parameters that have been set to non-default values. This can be used to have more compact representations.

Out:

Default representation:
LogisticRegression(penalty='l1')

With changed_only option:
LogisticRegression(penalty='l1')

Total running time of the script: ( 0 minutes 0.002 seconds)
6.20.2 ROC Curve with Visualization API

Scikit-learn defines a simple API for creating visualizations for machine learning. The key features of this API is to allow for quick plotting and visual adjustments without recalculation. In this example, we will demonstrate how to use the visualization API by comparing ROC curves.

```python
print(__doc__)

Load Data and Train a SVC

First, we load the wine dataset and convert it to a binary classification problem. Then, we train a support vector classifier on a training dataset.

```python
import matplotlib.pyplot as plt
from sklearn.svm import SVC
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import plot_roc_curve
from sklearn.datasets import load_wine
from sklearn.model_selection import train_test_split

X, y = load_wine(return_X_y=True)
y = y == 2

X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)
svc = SVC(random_state=42)
svc.fit(X_train, y_train)

Plotting the ROC Curve

Next, we plot the ROC curve with a single call to `sklearn.metrics.plot_roc_curve`. The returned `svc_disp` object allows us to continue using the already computed ROC curve for the SVC in future plots.

```python
svc_disp = plot_roc_curve(svc, X_test, y_test)
plt.show()
```

print(__doc__)

Load Data and Train a SVC

First, we load the wine dataset and convert it to a binary classification problem. Then, we train a support vector classifier on a training dataset.

```python
import matplotlib.pyplot as plt
from sklearn.svm import SVC
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import plot_roc_curve
from sklearn.datasets import load_wine
from sklearn.model_selection import train_test_split

X, y = load_wine(return_X_y=True)
y = y == 2

X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)
svc = SVC(random_state=42)
svc.fit(X_train, y_train)

Plotting the ROC Curve

Next, we plot the ROC curve with a single call to `sklearn.metrics.plot_roc_curve`. The returned `svc_disp` object allows us to continue using the already computed ROC curve for the SVC in future plots.

```python
svc_disp = plot_roc_curve(svc, X_test, y_test)
plt.show()
```
Training a Random Forest and Plotting the ROC Curve

We train a random forest classifier and create a plot comparing it to the SVC ROC curve. Notice how `svc_disp` uses `plot` to plot the SVC ROC curve without recomputing the values of the roc curve itself. Furthermore, we pass `alpha=0.8` to the plot functions to adjust the alpha values of the curves.

```python
rfc = RandomForestClassifier(n_estimators=10, random_state=42)
rfc.fit(X_train, y_train)
ax = plt.gca()
rfc_disp = plot_roc_curve(rfc, X_test, y_test, ax=ax, alpha=0.8)
svc_disp.plot(ax=ax, alpha=0.8)
plt.show()
```
6.20.3 Visualizations with Display Objects

In this example, we will construct display objects, `ConfusionMatrixDisplay`, `RocCurveDisplay`, and `PrecisionRecallDisplay` directly from their respective metrics. This is an alternative to using their corresponding plot functions when a model's predictions are already computed or expensive to compute. Note that this is advanced usage, and in general we recommend using their respective plot functions.

```python
print(__doc__)
```

Load Data and train model

For this example, we load a blood transfusion service center data set from OpenML <https://www.openml.org/d/1464>. This is a binary classification problem where the target is whether an individual donated blood. Then the data is split into a train and test dataset and a logistic regression is fitted with the train dataset.

```python
from sklearn.datasets import fetch_openml
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split
```

(continues on next page)
X, y = fetch_openml(data_id=1464, return_X_y=True)
X_train, X_test, y_train, y_test = train_test_split(X, y, stratify=y)
clf = make_pipeline(StandardScaler(), LogisticRegression(random_state=0))
clf.fit(X_train, y_train)

Create ConfusionMatrixDisplay

With the fitted model, we compute the predictions of the model on the test dataset. These predictions are used to compute the confusion matrix which is plotted with the ConfusionMatrixDisplay.

from sklearn.metrics import confusion_matrix
from sklearn.metrics import ConfusionMatrixDisplay

y_pred = clf.predict(X_test)
cm = confusion_matrix(y_test, y_pred)
cm_display = ConfusionMatrixDisplay(cm).plot()
Create `RocCurveDisplay`

The roc curve requires either the probabilities or the non-thresholded decision values from the estimator. Since the logistic regression provides a decision function, we will use it to plot the roc curve:

```python
from sklearn.metrics import roc_curve
from sklearn.metrics import RocCurveDisplay
y_score = clf.decision_function(X_test)
fpr, tpr, _ = roc_curve(y_test, y_score, pos_label=clf.classes_[1])
roc_display = RocCurveDisplay(fpr=fpr, tpr=tpr).plot()
```

Create `PrecisionRecallDisplay`

Similarly, the precision recall curve can be plotted using `y_score` from the previous sections.

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import PrecisionRecallDisplay
prec, recall, _ = precision_recall_curve(y_test, y_score, pos_label=clf.classes_[1])
pr_display = PrecisionRecallDisplay(precision=prec, recall=recall).plot()
```
Combining the display objects into a single plot

The display objects store the computed values that were passed as arguments. This allows for the visualizations to be easily combined using matplotlib’s API. In the following example, we place the displays next to each other in a row.

```python
import matplotlib.pyplot as plt
fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
roc_display.plot(ax=ax1)
pr_display.plot(ax=ax2)
plt.show()
```
6.20.4 Isotonic Regression

An illustration of the isotonic regression on generated data (non-linear monotonic trend with homoscedastic uniform noise).

The isotonic regression algorithm finds a non-decreasing approximation of a function while minimizing the mean squared error on the training data. The benefit of such a non-parametric model is that it does not assume any shape for the target function besides monotonicity. For comparison a linear regression is also presented.

The plot on the right-hand side shows the model prediction function that results from the linear interpolation of thresholds points. The thresholds points are a subset of the training input observations and their matching target values are computed by the isotonic non-parametric fit.

```python
print(__doc__)

# Author: Nelle Varoquaux <nelle.varoquaux@gmail.com>
#         Alexandre Gramfort <alexandre.gramfort@inria.fr>
# License: BSD

import numpy as np
import matplotlib.pyplot as plt
from matplotlib.collections import LineCollection
from sklearn.linear_model import LinearRegression
from sklearn.isotonic import IsotonicRegression
from sklearn.utils import check_random_state
```

Total running time of the script: ( 0 minutes 0.421 seconds)
n = 100
x = np.arange(n)
rs = check_random_state(0)
y = rs.randint(-50, 50, size=(n,)) + 50. * np.log1p(np.arange(n))

Fit IsotonicRegression and LinearRegression models:

```
ir = IsotonicRegression(out_of_bounds="clip")
y_ = ir.fit_transform(x, y)
lr = LinearRegression()
lr.fit(x[:, np.newaxis], y)  # x needs to be 2d for LinearRegression
```

Plot results:

```
segments = [[[i, y[i]], [i, y_[i]]] for i in range(n)]
lc = LineCollection(segments, zorder=0)
lc.set_array(np.ones(len(y)))
lc.set_linewidths(np.full(n, 0.5))

fig, (ax0, ax1) = plt.subplots(ncols=2, figsize=(12, 6))
ax0.plot(x, y, 'C0.', markersize=12)
ax0.plot(x, y_, 'C1.-', markersize=12)
ax0.plot(x, lr.predict(x[:, np.newaxis]), 'C2-')
ax0.add_collection(lc)
ax0.legend(('Training data', 'Isotonic fit', 'Linear fit'), loc='lower right')
ax0.set_title('Isotonic regression fit on noisy data (n=%d)' % n)

x_test = np.linspace(-10, 110, 1000)
ax1.plot(x_test, ir.predict(x_test), 'C1-')
ax1.plot(ir.X_thresholds_, ir.y_thresholds_, 'C1.', markersize=12)
ax1.set_title("Prediction function (%d thresholds)" % len(ir.X_thresholds_))

plt.show()
```
Note that we explicitly passed `out_of_bounds="clip"` to the constructor of `IsotonicRegression` to control the way the model extrapolates outside of the range of data observed in the training set. This “clipping” extrapolation can be seen on the plot of the decision function on the right-hand.

**Total running time of the script:** ( 0 minutes 0.182 seconds)

### 6.20.5 Advanced Plotting With Partial Dependence

The `plot_partial_dependence` function returns a `PartialDependenceDisplay` object that can be used for plotting without needing to recalculate the partial dependence. In this example, we show how to plot partial dependence plots and how to quickly customize the plot with the visualization API.

**Note:** See also *ROC Curve with Visualization API*

```python
print(__doc__)

import pandas as pd
import matplotlib.pyplot as plt
from sklearn.datasets import load_diabetes
from sklearn.neural_network import MLPRegressor
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline
from sklearn.tree import DecisionTreeRegressor
from sklearn.inspection import plot_partial_dependence
```
Train models on the diabetes dataset

First, we train a decision tree and a multi-layer perceptron on the diabetes dataset.

```python
diabetes = load_diabetes()
X = pd.DataFrame(diabetes.data, columns=diabetes.feature_names)
y = diabetes.target

tree = DecisionTreeRegressor()
mlp = make_pipeline(StandardScaler(),
    MLPRegressor(hidden_layer_sizes=(100, 100),
                  tol=1e-2, max_iter=500, random_state=0))

tree.fit(X, y)
mlp.fit(X, y)
```

Plotting partial dependence for two features

We plot partial dependence curves for features “age” and “bmi” (body mass index) for the decision tree. With two features, `plot_partial_dependence` expects to plot two curves. Here the plot function place a grid of two plots using the space defined by `ax`.

```python
fig, ax = plt.subplots(figsize=(12, 6))
ax.set_title("Decision Tree")
tree_disp = plot_partial_dependence(tree, X, ["age", "bmi"], ax=ax)
```

The partial dependence curves can be plotted for the multi-layer perceptron. In this case, `line_kw` is passed to `plot_partial_dependence` to change the color of the curve.

```python
fig, ax = plt.subplots(figsize=(12, 6))
ax.set_title("Multi-layer Perceptron")
mlp_disp = plot_partial_dependence(mlp, X, ["age", "bmi"], ax=ax,
                                    line_kw="color": "red")
```
Plotting partial dependence of the two models together

The `tree Disp` and `mlp Disp` `PartialDependenceDisplay` objects contain all the computed information needed to recreate the partial dependence curves. This means we can easily create additional plots without needing to recompute the curves.

One way to plot the curves is to place them in the same figure, with the curves of each model on each row. First, we create a figure with two axes within two rows and one column. The two axes are passed to the `plot` functions of `tree Disp` and `mlp Disp`. The given axes will be used by the plotting function to draw the partial dependence. The resulting plot places the decision tree partial dependence curves in the first row of the multi-layer perceptron in the second row.

```python
fig, (ax1, ax2) = plt.subplots(2, 1, figsize=(10, 10))
tree Disp.plot(ax=ax1)
ax1.set_title("Decision Tree")
mlp Disp.plot(ax=ax2, line_kw={"color": "red"})
ax2.set_title("Multi-layer Perceptron")
```

Another way to compare the curves is to plot them on top of each other. Here, we create a figure with one row and two
columns. The axes are passed into the plot function as a list, which will plot the partial dependence curves of each
model on the same axes. The length of the axes list must be equal to the number of plots drawn.
fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(10, 6))
tree_disp.plot(ax=[ax1, ax2], line_kw={"label": "Decision Tree"})
mlp_disp.plot(ax=[ax1, ax2], line_kw={"label": "Multi-layer Perceptron",
"color": "red"})
ax1.legend()
ax2.legend()

6.20. Miscellaneous

1337


tree_disp.axes_ is a numpy array container the axes used to draw the partial dependence plots. This can be passed to mlp_disp to have the same effect of drawing the plots on top of each other. Furthermore, the mlp_disp. figure_ stores the figure, which allows for resizing the figure after calling plot. In this case tree_disp.axes_ has two dimensions, thus plot will only show the y label and y ticks on the left most plot.
Plotting partial dependence for one feature

Here, we plot the partial dependence curves for a single feature, “age”, on the same axes. In this case, `tree_disp.axes_` is passed into the second plot function.

```python
tree_disp = plot_partial_dependence(tree, X, ["age"])  
mlp_disp = plot_partial_dependence(mlp, X, ["age"],  
    ax=tree_disp.axes_,  
    line_kw={"color": "red"})
```
6.20.6 Face completion with a multi-output estimators

This example shows the use of multi-output estimator to complete images. The goal is to predict the lower half of a face given its upper half.

The first column of images shows true faces. The next columns illustrate how extremely randomized trees, k nearest neighbors, linear regression and ridge regression complete the lower half of those faces.
Face completion with multi-output estimators

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import fetch_olivetti_faces
from sklearn.utils.validation import check_random_state
from sklearn.ensemble import ExtraTreesRegressor

(continues on next page)```

6.20.7 Multilabel classification

This example simulates a multi-label document classification problem. The dataset is generated randomly based on the following process:

- pick the number of labels: \( n \sim \text{Poisson}(n_{\text{labels}}) \)
- \( n \) times, choose a class \( c \sim \text{Multinomial}(\theta) \)
- pick the document length: \( k \sim \text{Poisson}(\text{length}) \)
- \( k \) times, choose a word: \( w \sim \text{Multinomial}(\theta_c) \)

In the above process, rejection sampling is used to make sure that \( n \) is more than 2, and that the document length is never zero. Likewise, we reject classes which have already been chosen. The documents that are assigned to both classes are plotted surrounded by two colored circles.

The classification is performed by projecting to the first two principal components found by PCA and CCA for visualisation purposes, followed by using the `OneVsRestClassifier` metaclassifier using two SVCs with linear kernels to learn a discriminative model for each class. Note that PCA is used to perform an unsupervised dimensionality reduction, while CCA is used to perform a supervised one.

Note: in the plot, “unlabeled samples” does not mean that we don’t know the labels (as in semi-supervised learning) but that the samples simply do not have a label.

6.20. Miscellaneous 1345
6.20.8 Comparing anomaly detection algorithms for outlier detection on toy datasets

This example shows characteristics of different anomaly detection algorithms on 2D datasets. Datasets contain one or two modes (regions of high density) to illustrate the ability of algorithms to cope with multimodal data.

For each dataset, 15% of samples are generated as random uniform noise. This proportion is the value given to the nu parameter of the OneClassSVM and the contamination parameter of the other outlier detection algorithms. Decision boundaries between inliers and outliers are displayed in black except for Local Outlier Factor (LOF) as it has no predict method to be applied on new data when it is used for outlier detection.

The OneClassSVM is known to be sensitive to outliers and thus does not perform very well for outlier detection. This estimator is best suited for novelty detection when the training set is not contaminated by outliers. That said, outlier detection in high-dimension, or without any assumptions on the distribution of the inlying data is very challenging, and a One-class SVM might give useful results in these situations depending on the value of its hyperparameters.

EllipticEnvelope assumes the data is Gaussian and learns an ellipse. It thus degrades when the data is not unimodal. Notice however that this estimator is robust to outliers.

IsolationForest and LocalOutlierFactor seem to perform reasonably well for multi-modal data sets. The advantage of LocalOutlierFactor over the other estimators is shown for the third data set, where the two modes have different densities. This advantage is explained by the local aspect of LOF, meaning that it only compares the score of abnormality of one sample with the scores of its neighbors.

Finally, for the last data set, it is hard to say that one sample is more abnormal than another sample as they are uniformly distributed in a hypercube. Except for the OneClassSVM which overfits a little, all estimators present decent solutions for this situation. In such a case, it would be wise to look more closely at the scores of abnormality of the samples as a good estimator should assign similar scores to all the samples.

While these examples give some intuition about the algorithms, this intuition might not apply to very high dimensional data.

Finally, note that parameters of the models have been here handpicked but that in practice they need to be adjusted. In the absence of labelled data, the problem is completely unsupervised so model selection can be a challenge.

6.20.9 The Johnson-Lindenstrauss bound for embedding with random projections

The Johnson-Lindenstrauss lemma states that any high dimensional dataset can be randomly projected into a lower dimensional Euclidean space while controlling the distortion in the pairwise distances.

import sys
from time import time
import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from sklearn.random_projection import johnson_lindenstrauss_min_dim
from sklearn.random_projection import SparseRandomProjection
from sklearn.datasets import fetch_20newsgroups_vectorized
from sklearn.datasets import load_digits
from sklearn.metrics.pairwise import euclidean_distances
from sklearn.utils.fixes import parse_version

(continues on next page)
# `normed` is being deprecated in favor of `density` in histograms

```python
if parse_version(matplotlib.__version__) >= parse_version('2.1'):
    density_param = {'density': True}
else:
    density_param = {'normed': True}
```

### Theoretical bounds

The distortion introduced by a random projection \( p \) is asserted by the fact that \( p \) is defining an \( \epsilon \)-embedding with good probability as defined by:

\[
(1 - \epsilon) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \epsilon) \|u - v\|^2
\]

Where \( u \) and \( v \) are any rows taken from a dataset of shape \((n_{\text{samples}}, n_{\text{features}})\) and \( p \) is a projection by a random Gaussian N(0, 1) matrix of shape \((n_{\text{components}}, n_{\text{features}})\) (or a sparse Achlioptas matrix).

The minimum number of components to guarantees the \( \epsilon \)-embedding is given by:

\[
n_{\text{components}} \geq 4 \log(n_{\text{samples}})/(\epsilon^2/2 - \epsilon^3/3)
\]

The first plot shows that with an increasing number of samples \( n_{\text{samples}} \), the minimal number of dimensions \( n_{\text{components}} \) increased logarithmically in order to guarantee an \( \epsilon \)-embedding.

```python
# range of admissible distortions
eps_range = np.linspace(0.1, 0.99, 5)
colors = plt.cm.Blues(np.linspace(0.3, 1.0, len(eps_range)))

# range of number of samples (observation) to embed
n_samples_range = np.logspace(1, 9, 9)

plt.figure()
for eps, color in zip(eps_range, colors):
    min_n_components = johnson_lindenstrauss_min_dim(n_samples_range, eps=eps)
    plt.loglog(n_samples_range, min_n_components, color=color)

plt.legend(["\epsilon = $%0.1f$" % eps for eps in eps_range], loc="lower right")
plt.xlabel("Number of observations to \epsilon-embed")
plt.ylabel("Minimum number of dimensions")
plt.title("Johnson-Lindenstrauss bounds: \#n_{\text{samples}} vs n_{\text{components}}")
plt.show()
```
The second plot shows that an increase of the admissible distortion $\text{eps}$ allows to reduce drastically the minimal number of dimensions $\text{n\_components}$ for a given number of samples $\text{n\_samples}$

```python
# range of admissible distortions
eps_range = np.linspace(0.01, 0.99, 100)

# range of number of samples (observation) to embed
n_samples_range = np.logspace(2, 6, 5)
colors = plt.cm.Blues(np.linspace(0.3, 1.0, len(n_samples_range)))

plt.figure()
for n_samples, color in zip(n_samples_range, colors):
    min_n_components = johnson_lindenstrauss_min_dim(n_samples, eps=eps_range)
    plt.semilogy(eps_range, min_n_components, color=color)

plt.legend(\"n\_samples = %d\ % n for n in n\_samples\_range\", loc=\"upper right\")
plt.xlabel(\"Distortion eps\")
plt.ylabel(\"Minimum number of dimensions\")
plt.title(\"Johnson-Lindenstrauss bounds:\nn\_components vs eps\")
plt.show()
```
Empirical validation

We validate the above bounds on the 20 newsgroups text document (TF-IDF word frequencies) dataset or on the digits dataset:

- for the 20 newsgroups dataset some 500 documents with 100k features in total are projected using a sparse random matrix to smaller euclidean spaces with various values for the target number of dimensions $n_{\text{components}}$.
- for the digits dataset, some 8x8 gray level pixels data for 500 handwritten digits pictures are randomly projected to spaces for various larger number of dimensions $n_{\text{components}}$.

The default dataset is the 20 newsgroups dataset. To run the example on the digits dataset, pass the `--use-digits-dataset` command line argument to this script.

```python
if '--use-digits-dataset' in sys.argv:
    data = load_digits().data[:500]
else:
    data = fetch_20newsgroups_vectorized().data[:500]
```

For each value of $n_{\text{components}}$, we plot:

- 2D distribution of sample pairs with pairwise distances in original and projected spaces as x and y axis respectively.
- 1D histogram of the ratio of those distances (projected / original).
n_samples, n_features = data.shape
print("Embedding %d samples with dim %d using various random projections"
    % (n_samples, n_features))

Out:

Embedding 500 samples with dim 130107 using various random projections
Projected 500 samples from 130107 to 300 in 0.268s
Random matrix with size: 1.292MB
Mean distances rate: 1.02 (0.18)
Projected 500 samples from 130107 to 1000 in 0.925s
Random matrix with size: 4.334MB
Mean distances rate: 1.06 (0.12)
Projected 500 samples from 130107 to 10000 in 9.444s
Random matrix with size: 43.287MB
Mean distances rate: 0.99 (0.03)

We can see that for low values of n_components the distribution is wide with many distorted pairs and a skewed distribution (due to the hard limit of zero ratio on the left as distances are always positives) while for larger values of n_components the distortion is controlled and the distances are well preserved by the random projection.
Remarks

According to the JL lemma, projecting 500 samples without too much distortion will require at least several thousands dimensions, irrespective of the number of features of the original dataset.

Hence using random projections on the digits dataset which only has 64 features in the input space does not make sense: it does not allow for dimensionality reduction in this case.

On the twenty newsgroups on the other hand the dimensionality can be decreased from 56436 down to 10000 while reasonably preserving pairwise distances.

6.20.10 Comparison of kernel ridge regression and SVR

Both kernel ridge regression (KRR) and SVR learn a non-linear function by employing the kernel trick, i.e., they learn a linear function in the space induced by the respective kernel which corresponds to a non-linear function in the original space. They differ in the loss functions (ridge versus epsilon-insensitive loss). In contrast to SVR, fitting a KRR can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR at prediction-time.

This example illustrates both methods on an artificial dataset, which consists of a sinusoidal target function and strong noise added to every fifth datapoint. The first figure compares the learned model of KRR and SVR when both complexity/regularization and bandwidth of the RBF kernel are optimized using grid-search. The learned functions are very similar; however, fitting KRR is approx. seven times faster than fitting SVR (both with grid-search). However, prediction of 100000 target values is more than three times faster with SVR since it has learned a sparse model using only approx. 1/3 of the 100 training datapoints as support vectors.

The next figure compares the time for fitting and prediction of KRR and SVR for different sizes of the training set. Fitting KRR is faster than SVR for medium-sized training sets (less than 1000 samples); however, for larger training sets SVR scales better. With regard to prediction time, SVR is faster than KRR for all sizes of the training set because of the learned sparse solution. Note that the degree of sparsity and thus the prediction time depends on the parameters epsilon and C of the SVR.
SVR versus Kernel Ridge

SVR (fit: 0.451s, predict: 0.276s)

KRR (fit: 0.152s, predict: 0.230s)

6.20.11 Explicit feature map approximation for RBF kernels

An example illustrating the approximation of the feature map of an RBF kernel.

It shows how to use `RBFSampler` and `Nystroem` to approximate the feature map of an RBF kernel for classification with an SVM on the digits dataset. Results using a linear SVM in the original space, a linear SVM using the approximate mappings and using a kernelized SVM are compared. Timings and accuracy for varying amounts of Monte Carlo samplings (in the case of `RBFSampler`, which uses random Fourier features) and different sized subsets of the training set (for `Nystroem`) for the approximate mapping are shown.

Please note that the dataset here is not large enough to show the benefits of kernel approximation, as the exact SVM is still reasonably fast.

Sampling more dimensions clearly leads to better classification results, but comes at a greater cost. This means there is a tradeoff between runtime and accuracy, given by the parameter `n_components`. Note that solving the Linear SVM and also the approximate kernel SVM could be greatly accelerated by using stochastic gradient descent via `SGDClassifier`. This is not easily possible for the case of the kernelized SVM.

from sklearn.decomposition import PCA

# The digits dataset
digits = datasets.load_digits(n_class=9)
```
Timing and accuracy plots

To apply an classifier on this data, we need to flatten the image, to turn the data in a (samples, feature) matrix:

```python
n_samples = len(digits.data)
data = digits.data / 16.
data -= data.mean(axis=0)

# We learn the digits on the first half of the digits
data_train, targets_train = (data[:n_samples // 2],
                             digits.target[:n_samples // 2])

# Now predict the value of the digit on the second half:
data_test, targets_test = (data[n_samples // 2:],
                         digits.target[n_samples // 2:])
# data_test = scaler.transform(data_test)

# Create a classifier: a support vector classifier
kernel_svm = svm.SVC(gamma=.2)
linear_svm = svm.LinearSVC()

# create pipeline from kernel approximation
# and linear svm
feature_map_fourier = RBFSampler(gamma=.2, random_state=1)
feature_map_nystroem = Nystroem(gamma=.2, random_state=1)

plt.show()
Decision Surfaces of RBF Kernel SVM and Linear SVM

The second plot visualized the decision surfaces of the RBF kernel SVM and the linear SVM with approximate kernel maps. The plot shows decision surfaces of the classifiers projected onto the first two principal components of the data. This visualization should be taken with a grain of salt since it is just an interesting slice through the decision surface in 64 dimensions. In particular note that a datapoint (represented as a dot) does not necessarily be classified into the region it is lying in, since it will not lie on the plane that the first two principal components span. The usage of \texttt{RBFSampler} and \texttt{Nystroem} is described in detail in \textit{Kernel Approximation}.

```python
# visualize the decision surface, projected down to the first # two principal components of the dataset
pca = PCA(n_components=8).fit(data_train)
X = pca.transform(data_train)

# Generate grid along first two principal components
multiples = np.arange(-2, 2, 0.1)
# steps along first component
first = multiples[:, np.newaxis] * pca.components_[0, :]
# steps along second component
second = multiples[:, np.newaxis] * pca.components_[1, :]
# combine
grid = first[np.newaxis, :, :] + second[:, np.newaxis, :]
flat_grid = grid.reshape(-1, data.shape[1])

# title for the plots
titles = ['SVC with rbf kernel',
    'SVC (linear kernel) \n with Fourier rbf feature map
    n_components=100',
    'SVC (linear kernel) \n with Nystroem rbf feature map
    n_components=100']

plt.figure(figsize=(18, 7.5))
plt.rcParams.update({'font.size': 14})
# predict and plot
for i, clf in enumerate((kernel_svm, nystroem_approx_svm,
                         fourier_approx_svm)):
    # Plot the decision boundary. For that, we will assign a color to each # point in the mesh [x_min, x_max]x[y_min, y_max].
    plt.subplot(1, 3, i + 1)
    Z = clf.predict(flat_grid)
    # Put the result into a color plot
    Z = Z.reshape(grid.shape[:-1])
    plt.contourf(multiples, multiples, Z, cmap=plt.cm.Paired)
```

(continues on next page)
plt.axis('off')

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=targets_train, cmap=plt.cm.Paired,
    edgecolors=(0, 0, 0))

plt.title(titles[i])
plt.tight_layout()
plt.show()

## 6.21 Missing Value Imputation

Examples concerning the `sklearn.impute` module.

### 6.21.1 Imputing missing values with variants of IterativeImputer

The `IterativeImputer` class is very flexible - it can be used with a variety of estimators to do round-robin regression, treating every variable as an output in turn.

In this example we compare some estimators for the purpose of missing feature imputation with `IterativeImputer`:

- `BayesianRidge`: regularized linear regression
- `DecisionTreeRegressor`: non-linear regression
- `ExtraTreesRegressor`: similar to missForest in R
- `KNeighborsRegressor`: comparable to other KNN imputation approaches

Of particular interest is the ability of `IterativeImputer` to mimic the behavior of missForest, a popular imputation package for R. In this example, we have chosen to use `ExtraTreesRegressor` instead of `RandomForestRegressor` (as in missForest) due to its increased speed.

Note that `KNeighborsRegressor` is different from KNN imputation, which learns from samples with missing values by using a distance metric that accounts for missing values, rather than imputing them.
The goal is to compare different estimators to see which one is best for the `IterativeImputer` when using a `BayesianRidge` estimator on the California housing dataset with a single value randomly removed from each row. For this particular pattern of missing values we see that `ExtraTreesRegressor` and `BayesianRidge` give the best results.

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
import pandas as pd

# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_iterative_imputer  # noqa
from sklearn.datasets import fetch_california_housing

Partial running time of the script: (0 minutes 18.403 seconds)

6.21.2 Imputing missing values before building an estimator

Missing values can be replaced by the mean, the median or the most frequent value using the basic SimpleImputer.

In this example we will investigate different imputation techniques:

- imputation by the constant value 0
- imputation by the mean value of each feature combined with a missing-ness indicator auxiliary variable
- k nearest neighbor imputation
- iterative imputation

We will use two datasets: Diabetes dataset which consists of 10 feature variables collected from diabetes patients with an aim to predict disease progression and California Housing dataset for which the target is the median house value for California districts.

As neither of these datasets have missing values, we will remove some values to create new versions with artificially missing data. The performance of RandomForestRegressor on the full original dataset is then compared the performance on the altered datasets with the artificially missing values imputed using different techniques.

```
print(__doc__)

# Authors: Maria Telenczuk <https://github.com/maikia>
# License: BSD 3 clause
```

Download the data and make missing values sets

First we download the two datasets. Diabetes dataset is shipped with scikit-learn. It has 442 entries, each with 10 features. California Housing dataset is much larger with 20640 entries and 8 features. It needs to be downloaded. We will only use the first 400 entries for the sake of speeding up the calculations but feel free to use the whole dataset.

```
import numpy as np

from sklearn.datasets import fetch_california_housing
from sklearn.datasets import load_diabetes

rng = np.random.RandomState(42)

X_diabetes, y_diabetes = load_diabetes(return_X_y=True)
X_california, y_california = fetch_california_housing(return_X_y=True)
X_california = X_california[:400]
y_california = y_california[:400]
```
def add_missing_values(X_full, y_full):
    n_samples, n_features = X_full.shape

    # Add missing values in 75% of the lines
    missing_rate = 0.75
    n_missing_samples = int(n_samples * missing_rate)

    missing_samples = np.zeros(n_samples, dtype=bool)
    missing_samples[:n_missing_samples] = True

    rng.shuffle(missing_samples)
    missing_features = rng.randint(0, n_features, n_missing_samples)
    X_missing = X_full.copy()
    X_missing[missing_samples, missing_features] = np.nan
    y_missing = y_full.copy()

    return X_missing, y_missing

X_miss_california, y_miss_california = add_missing_values(X_california, y_california)
X_miss_diabetes, y_miss_diabetes = add_missing_values(X_diabetes, y_diabetes)

Impute the missing data and score

Now we will write a function which will score the results on the differently imputed data. Let’s look at each imputer separately:

rng = np.random.RandomState(0)

from sklearn.ensemble import RandomForestRegressor

# To use the experimental IterativeImputer, we need to explicitly ask for it:
from sklearn.experimental import enable_iterative_imputer  # noqa
from sklearn.impute import SimpleImputer, KNNImputer, IterativeImputer
from sklearn.model_selection import cross_val_score
from sklearn.pipeline import make_pipeline

N_SPLITS = 5
regressor = RandomForestRegressor(random_state=0)
Missing information

In addition to imputing the missing values, the imputers have an `add_indicator` parameter that marks the values that were missing, which might carry some information.

```python
def get_scores_for_imputer(imputer, X_missing, y_missing):
    estimator = make_pipeline(imputer, regressor)
    impute_scores = cross_val_score(estimator, X_missing, y_missing,
                                      scoring='neg_mean_squared_error',
                                      cv=N_SPLITS)
    return impute_scores
```

```python
x_labels = ['Full data',
            'Zero imputation',
            'Mean Imputation',
            'KNN Imputation',
            'Iterative imputation']
```

```python
mses_california = np.zeros(5)
stds_california = np.zeros(5)
mses_diabetes = np.zeros(5)
stds_diabetes = np.zeros(5)
```

Estimate the score

First, we want to estimate the score on the original data:

```python
def get_full_score(X_full, y_full):
    full_scores = cross_val_score(regressor, X_full, y_full,
                                   scoring='neg_mean_squared_error',
                                   cv=N_SPLITS)
    return full_scores.mean(), full_scores.std()
```

```python
mses_california[0], stds_california[0] = get_full_score(X_california, y_california)
mses_diabetes[0], stds_diabetes[0] = get_full_score(X_diabetes, y_diabetes)
```

Replace missing values by 0

Now we will estimate the score on the data where the missing values are replaced by 0:

```python
def get_impute_zero_score(X_missing, y_missing):
    imputer = SimpleImputer(missing_values=np.nan, add_indicator=True,
                             strategy='constant', fill_value=0)
    zero_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return zero_impute_scores.mean(), zero_impute_scores.std()
```

```python
mses_california[1], stds_california[1] = get_impute_zero_score(X_miss_california, y_miss_california)
```

(continues on next page)
mses_diabetes[1], stds_diabetes[1] = get_impute_zero_score(X_miss_diabetes, y_miss_diabetes)

kNN-imputation of the missing values

**KNNImputer** imputes missing values using the weighted or unweighted mean of the desired number of nearest neighbors.

```python
def get_impute_knn_score(X_missing, y_missing):
    imputer = KNNImputer(missing_values=np.nan, add_indicator=True)
    knn_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return knn_impute_scores.mean(), knn_impute_scores.std()
```

mses_california[2], stds_california[2] = get_impute_knn_score(X_miss_california, y_miss_california)
mses_diabetes[2], stds_diabetes[2] = get_impute_knn_score(X_miss_diabetes, y_miss_diabetes)

Impute missing values with mean

```python
def get_impute_mean(X_missing, y_missing):
    imputer = SimpleImputer(missing_values=np.nan, strategy="mean",
                            add_indicator=True)
    mean_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return mean_impute_scores.mean(), mean_impute_scores.std()
```

mses_california[3], stds_california[3] = get_impute_mean(X_miss_california, y_miss_california)
mses_diabetes[3], stds_diabetes[3] = get_impute_mean(X_miss_diabetes, y_miss_diabetes)

Iterative imputation of the missing values

Another option is the **IterativeImputer**. This uses round-robin linear regression, modeling each feature with missing values as a function of other features, in turn. The version implemented assumes Gaussian (output) variables. If your features are obviously non-normal, consider transforming them to look more normal to potentially improve performance.

```python
def get_impute_iterative(X_missing, y_missing):
    imputer = IterativeImputer(missing_values=np.nan, add_indicator=True,
                               random_state=0, n_nearest_features=5,
                               sample_posterior=True)
    iterative_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return iterative_impute_scores.mean(), iterative_impute_scores.std()
```

(continues on next page)
mses_california[4], stds_california[4] = get_impute_iterative(X_miss_california, y_miss_california)
mses_diabetes[4], stds_diabetes[4] = get_impute_iterative(X_miss_diabetes, y_miss_diabetes)

mses_diabetes = mses_diabetes * -1
mses_california = mses_california * -1

Plot the results

Finally we are going to visualize the score:

```python
import matplotlib.pyplot as plt
n_bars = len(mses_diabetes)
xval = np.arange(n_bars)
colors = ['r', 'g', 'b', 'orange', 'black']

# plot diabetes results
plt.figure(figsize=(12, 6))
ax1 = plt.subplot(121)
for j in xval:
    ax1.barh(j, mses_diabetes[j], xerr=stds_diabetes[j],
    color=colors[j], alpha=0.6, align='center')
ax1.set_title('Imputation Techniques with Diabetes Data')
ax1.set_xlim(left=np.min(mses_diabetes) * 0.9,
    right=np.max(mses_diabetes) * 1.1)
ax1.set_yticks(xval)
ax1.set_xlabel('MSE')
ax1.invert_yaxis()
ax1.set_yticklabels(x_labels)

# plot california dataset results
ax2 = plt.subplot(122)
for j in xval:
    ax2.barh(j, mses_california[j], xerr=stds_california[j],
    color=colors[j], alpha=0.6, align='center')
ax2.set_title('Imputation Techniques with California Data')
ax2.set_xticks(xval)
ax2.set_xlabel('MSE')
ax2.invert_yaxis()
ax2.set_yticklabels([''] * n_bars)
plt.show()
```

# You can also try different techniques. For instance, the median is a more
# robust estimator for data with high magnitude variables which could dominate
# results (otherwise known as a 'long tail').

6.22 Model Selection

Examples related to the `sklearn.model_selection` module.

6.22.1 Plotting Cross-Validated Predictions

This example shows how to use `cross_val_predict` to visualize prediction errors.
from sklearn import datasets
from sklearn.model_selection import cross_val_predict
from sklearn import linear_model
import matplotlib.pyplot as plt

lr = linear_model.LinearRegression()
X, y = datasets.load_diabetes(return_X_y=True)

# cross_val_predict returns an array of the same size as `y` where each entry
# is a prediction obtained by cross validation:
predicted = cross_val_predict(lr, X, y, cv=10)

fig, ax = plt.subplots()
ax.scatter(y, predicted, edgecolors=(0, 0, 0))
ax.plot([y.min(), y.max()], [y.min(), y.max()], 'k--', lw=4)
ax.set_xlabel('Measured')
ax.set_ylabel('Predicted')
plt.show()

Total running time of the script: ( 0 minutes 0.103 seconds)
### 6.22.2 Confusion matrix

Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set. The diagonal elements represent the number of points for which the predicted label is equal to the true label, while off-diagonal elements are those that are mislabeled by the classifier. The higher the diagonal values of the confusion matrix the better, indicating many correct predictions.

The figures show the confusion matrix with and without normalization by class support size (number of elements in each class). This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified.

Here the results are not as good as they could be as our choice for the regularization parameter $C$ was not the best. In real life applications this parameter is usually chosen using Tuning the hyper-parameters of an estimator.
Out:

Confusion matrix, without normalization
[[13 0 0]
 [0 10 6]
 [0 0 9]]

Normalized confusion matrix
[[1. 0. 0. ]
 [0. 0.62 0.38]
 [0. 0. 1. ]]
X = iris.data
y = iris.target
class_names = iris.target_names

# Split the data into a training set and a test set
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)

# Run classifier, using a model that is too regularized (C too low) to see
# the impact on the results
classifier = svm.SVC(kernel='linear', C=0.01).fit(X_train, y_train)

np.set_printoptions(precision=2)

# Plot non-normalized confusion matrix
titles_options = ["Confusion matrix, without normalization", None],
                ["Normalized confusion matrix", 'true'])
for title, normalize in titles_options:
    disp = plot_confusion_matrix(classifier, X_test, y_test,
                                  display_labels=class_names,
                                  cmap=plt.cm.Blues,
                                  normalize=normalize)
    disp.ax_.set_title(title)
    print(title)
    print(disp.confusion_matrix)
plt.show()

Total running time of the script: ( 0 minutes 0.227 seconds)

6.22.3 Plotting Validation Curves

In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter gamma. For very low values of gamma, you can see that both the training score and the validation score are low. This is called underfitting. Medium values of gamma will result in high values for both scores, i.e. the classifier is performing fairly well. If gamma is too high, the classifier will overfit, which means that the training score is good but the validation score is poor.
...import matplotlib.pyplot as plt
import numpy as np
from sklearn.datasets import load_digits
from sklearn.svm import SVC
from sklearn.model_selection import validation_curve
X, y = load_digits(return_X_y=True)
param_range = np.logspace(-6, -1, 5)
train_scores, test_scores = validation_curve(SVC(), X, y, param_name="gamma", param_range=param_range, scoring="accuracy", n_jobs=1)
train_scores_mean = np.mean(train_scores, axis=1)
train_scores_std = np.std(train_scores, axis=1)
test_scores_mean = np.mean(test_scores, axis=1)
test_scores_std = np.std(test_scores, axis=1)
plt.title("Validation Curve with SVM")
plt.xscale("log")
plt.ylabel("Score")
plt.ylim(0.0, 1.1)
lw = 2
plt.semilogx(param_range, train_scores_mean, label="Training score",
            color="darkorange", lw=lw)
plt.fill_between(param_range, train_scores_mean - train_scores_std,
                 train_scores_mean + train_scores_std, alpha=0.2,
                 color="darkorange", lw=lw)
plt.semilogx(param_range, test_scores_mean, label="Cross-validation score",
            color="navy", lw=lw)
plt.fill_between(param_range, test_scores_mean - test_scores_std,
                 test_scores_mean + test_scores_std, alpha=0.2,
                 color="navy", lw=lw)
plt.legend(loc="best")
plt.show()

**Total running time of the script:** ( 0 minutes 13.396 seconds)

### 6.22.4 Detection error tradeoff (DET) curve

In this example, we compare receiver operating characteristic (ROC) and detection error tradeoff (DET) curves for different classification algorithms for the same classification task.

DET curves are commonly plotted in normal deviate scale. To achieve this plot, the `plot_det_curve` transforms the error rates as returned by the `det_curve` and the axis scale using `scipy.stats.norm`.

The point of this example is to demonstrate two properties of DET curves, namely:

1. It might be easier to visually assess the overall performance of different classification algorithms using DET curves over ROC curves. Due to the linear scale used for plotting ROC curves, different classifiers usually only differ in the top left corner of the graph and appear similar for a large part of the plot. On the other hand, because DET curves represent straight lines in normal deviate scale. As such, they tend to be distinguishable as a whole and the area of interest spans a large part of the plot.

2. DET curves give the user direct feedback of the detection error tradeoff to aid in operating point analysis. The user can deduce directly from the DET-curve plot at which rate false-negative error rate will improve when willing to accept an increase in false-positive error rate (or vice-versa).

The plots in this example compare ROC curves on the left side to corresponding DET curves on the right. There is no particular reason why these classifiers have been chosen for the example plot over other classifiers available in scikit-learn.

**Note:**

- See `sklearn.metrics.roc_curve` for further information about ROC curves.
- See `sklearn.metrics.det_curve` for further information about DET curves.
- This example is loosely based on *Classifier comparison* example.
import matplotlib.pyplot as plt

from sklearn.datasets import make_classification
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import plot_det_curve
from sklearn.metrics import plot_roc_curve
from sklearn.model_selection import train_test_split
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import StandardScaler
from sklearn.svm import LinearSVC

N_SAMPLES = 1000

classifiers = {
    "Linear SVM": make_pipeline(StandardScaler(), LinearSVC(C=0.025)),
    "Random Forest": RandomForestClassifier(max_depth=5, n_estimators=10, max_features=1),
}

X, y = make_classification(n_samples=N_SAMPLES, n_features=2, n_redundant=0, n_informative=2,
                           random_state=1, n_clusters_per_class=1)

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=.4, random_state=0)

# prepare plots
fig, [ax_roc, ax_det] = plt.subplots(1, 2, figsize=(11, 5))

for name, clf in classifiers.items():
    clf.fit(X_train, y_train)

    plot_roc_curve(clf, X_test, y_test, ax=ax_roc, name=name)
    plot_det_curve(clf, X_test, y_test, ax=ax_det, name=name)

ax_roc.set_title('Receiver Operating Characteristic (ROC) curves')
ax_det.set_title('Detection Error Tradeoff (DET) curves')

(continues on next page)
Total running time of the script: ( 0 minutes 0.200 seconds)

6.22.5 Successive Halving Iterations

This example illustrates how a successive halving search (\texttt{HalvingGridSearchCV} and \texttt{HalvingRandomSearchCV}) iteratively chooses the best parameter combination out of multiple candidates.

```python
import pandas as pd
from sklearn import datasets
import matplotlib.pyplot as plt
from scipy.stats import randint
import numpy as np

from sklearn.experimental import enable_halving_search_cv # noqa
from sklearn.model_selection import HalvingRandomSearchCV
from sklearn.ensemble import RandomForestClassifier

print(__doc__)

We first define the parameter space and train a \texttt{HalvingRandomSearchCV} instance.

```python
rng = np.random.RandomState(0)
X, y = datasets.make_classification(n_samples=700, random_state=rng)
clf = RandomForestClassifier(n_estimators=20, random_state=rng)

param_dist = {
    "max_depth": [3, None],
    "max_features": randint(1, 11),
    "min_samples_split": randint(2, 11),
    "bootstrap": [True, False],
    "criterion": ["gini", "entropy"]
}

rsh = HalvingRandomSearchCV(
estimator=clf,
param_distributions=param_dist,
factor=2,
random_state=rng)
rsh.fit(X, y)
```

We can now use the \texttt{cv_results_} attribute of the search estimator to inspect and plot the evolution of the search.

```python
results = pd.DataFrame(rsh.cv_results_)
results[\'params_str\'] = results.params.apply(str)
results.drop_duplicates(subset=(\'params_str\', \'iter\'), inplace=True)
mean_scores = results.pivot(index='iter', columns='params_str',
                           values='mean_test_score')
```

(continues on next page)
```
ax = mean_scores.plot(legend=False, alpha=.6)

labels = [
    f'iter={i}\
n_samples={rsh.n_resources_[i]}\
n_candidates={rsh.n_candidates_[i]}'
    for i in range(rsh.n_iterations_)
]

ax.set_xticks(range(rsh.n_iterations_))
ax.set_xticklabels(labels, rotation=45, multialignment='left')
ax.set_title('Scores of candidates over iterations')
ax.set_ylabel('mean test score', fontsize=15)
ax.set_xlabel('iterations', fontsize=15)
plt.tight_layout()
plt.show()
```
Number of candidates and amount of resource at each iteration

At the first iteration, a small amount of resources is used. The resource here is the number of samples that the estimators are trained on. All candidates are evaluated.

At the second iteration, only the best half of the candidates is evaluated. The number of allocated resources is doubled: candidates are evaluated on twice as many samples.

This process is repeated until the last iteration, where only 2 candidates are left. The best candidate is the candidate that has the best score at the last iteration.

Total running time of the script: (0 minutes 8.635 seconds)

6.22.6 Underfitting vs. Overfitting

This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions. The plot shows the function that we want to approximate, which is a part of the cosine function. In addition, the samples from the real function and the approximations of different models are displayed. The models have polynomial features of different degrees. We can see that a linear function (polynomial with degree 1) is not sufficient to fit the training samples. This is called underfitting. A polynomial of degree 4 approximates the true function almost perfectly. However, for higher degrees the model will overfit the training data, i.e. it learns the noise of the training data. We evaluate quantitatively overfitting / underfitting by using cross-validation. We calculate the mean squared error (MSE) on the validation set, the higher, the less likely the model generalizes correctly from the training data.

```python
print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import PolynomialFeatures
from sklearn.linear_model import LinearRegression
from sklearn.model_selection import cross_val_score

def true_fun(X):
    return np.cos(1.5 * np.pi * X)

np.random.seed(0)
```
n_samples = 30
degrees = [1, 4, 15]
X = np.sort(np.random.rand(n_samples))
y = true_fun(X) + np.random.randn(n_samples) * 0.1

plt.figure(figsize=(14, 5))
for i in range(len(degrees)):
    ax = plt.subplot(1, len(degrees), i + 1)
    plt.setp(ax, xticks=(), yticks=())
    polynomial_features = PolynomialFeatures(degree=degrees[i],
                                              include_bias=False)
    linear_regression = LinearRegression()
    pipeline = Pipeline([("polynomial_features", polynomial_features),
                         ("linear_regression", linear_regression)])
    pipeline.fit(X[:, np.newaxis], y)

    # Evaluate the models using crossvalidation
    scores = cross_val_score(pipeline, X[:, np.newaxis], y,
                              scoring="neg_mean_squared_error", cv=10)

    X_test = np.linspace(0, 1, 100)
    plt.plot(X_test, pipeline.predict(X_test[:, np.newaxis]), label="Model")
    plt.plot(X_test, true_fun(X_test), label="True function")
    plt.scatter(X, y, edgecolor='b', s=20, label="Samples")
    plt.xlabel("x")
    plt.ylabel("y")
    plt.xlim((0, 1))
    plt.ylim((-2, 2))
    plt.legend(loc="best")
    plt.title("Degree {}

MSE = {:.2e}(+/-.2e)").format(
    degrees[i], -scores.mean(), scores.std())

plt.show()

6.22.8 Comparing randomized search and grid search for hyperparameter estimation

Compare randomized search and grid search for optimizing hyperparameters of a linear SVM with SGD training. All parameters that influence the learning are searched simultaneously (except for the number of estimators, which poses a time / quality tradeoff).

The randomized search and the grid search explore exactly the same space of parameters. The result in parameter settings is quite similar, while the run time for randomized search is drastically lower.

The performance is may slightly worse for the randomized search, and is likely due to a noise effect and would not carry over to a held-out test set.

Note that in practice, one would not search over this many different parameters simultaneously using grid search, but pick only the ones deemed most important.

Out:
RandomizedSearchCV took 20.40 seconds for 20 candidates parameter settings.
Model with rank: 1
Mean validation score: 0.920 (std: 0.028)

6.22.9 Train error vs Test error

Illustration of how the performance of an estimator on unseen data (test data) is not the same as the performance on training data. As the regularization increases the performance on train decreases while the performance on test is optimal within a range of values of the regularization parameter. The example with an Elastic-Net regression model and the performance is measured using the explained variance a.k.a. $R^2$.

6.22.10 Receiver Operating Characteristic (ROC) with cross validation

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality using cross-validation. ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better. The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

This example shows the ROC response of different datasets, created from K-fold cross-validation. Taking all of these curves, it is possible to calculate the mean area under curve, and see the variance of the curve when the training set is split into different subsets. This roughly shows how the classifier output is affected by changes in the training data, and how different the splits generated by K-fold cross-validation are from one another.

Note:

See also sklearn.metrics.roc_auc_score, sklearn.model_selection.cross_val_score, Receiver Operating Characteristic (ROC),

6.22.11 Nested versus non-nested cross-validation

This example compares non-nested and nested cross-validation strategies on a classifier of the iris data set. Nested cross-validation (CV) is often used to train a model in which hyperparameters also need to be optimized. Nested CV estimates the generalization error of the underlying model and its (hyper)parameter search. Choosing the parameters that maximize non-nested CV biases the model to the dataset, yielding an overly-optimistic score.

Model selection without nested CV uses the same data to tune model parameters and evaluate model performance. Information may thus “leak” into the model and overfit the data. The magnitude of this effect is primarily dependent on the size of the dataset and the stability of the model. See Cawley and Talbot¹ for an analysis of these issues.

To avoid this problem, nested CV effectively uses a series of train/validation/test set splits. In the inner loop (here executed by GridSearchCV), the score is approximately maximized by fitting a model to each training set, and then directly maximized in selecting (hyper)parameters over the validation set. In the outer loop (here in cross_val_score), generalization error is estimated by averaging test set scores over several dataset splits.

The example below uses a support vector classifier with a non-linear kernel to build a model with optimized hyperparameters by grid search. We compare the performance of non-nested and nested CV strategies by taking the difference between their scores.

6.22.12 Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

Multiple metric parameter search can be done by setting the `scoring` parameter to a list of metric scorer names or a dict mapping the scorer names to the scorer callables.

The scores of all the scorers are available in the `cv_results_` dict at keys ending in `'_<scorer_name>'` ('mean_test_precision', 'rank_test_precision', etc...)

The `best_estimator_`, `best_index_`, `best_score_` and `best_params_` correspond to the scorer (key) that is set to the `refit` attribute.

grid.fit(X, y)

n_components = grid.cv_results_['param_reduce_dim__n_components']
test_scores = grid.cv_results_['mean_test_score']

plt.figure()
plt.bar(n_components, test_scores, width=1.3, color='b')
lower = lower_bound(grid.cv_results_)
plt.axhline(np.max(test_scores), linestyle='--', color='y',
    label='Best score')
plt.axhline(lower, linestyle='--', color='.5', label='Best score - 1 std')

plt.title("Balance model complexity and cross-validated score")
plt.xlabel('Number of PCA components used')
plt.ylabel('Digit classification accuracy')
plt.xticks(n_components.tolist())
plt.ylim((0, 1.0))
plt.legend(loc='upper left')

best_index_ = grid.best_index_
print("The best_index_ is %d" % best_index_)
print("The n_components selected is %d" % n_components[best_index_])
print("The corresponding accuracy score is %.2f" 
    % grid.cv_results_['mean_test_score'][best_index_])
plt.show()
We first define the parameter space for an SVC estimator, and compute the time required to train a HalvingGridSearchCV instance, as well as a GridSearchCV instance.

```python
rng = np.random.RandomState(0)
X, y = datasets.make_classification(n_samples=1000, random_state=rng)

gammas = [1e-1, 1e-2, 1e-3, 1e-4, 1e-5, 1e-6, 1e-7]
Cs = [1, 10, 100, 1e3, 1e4, 1e5]
param_grid = {'gamma': gammas, 'C': Cs}

clf = SVC(random_state=rng)
tic = time()
gsh = HalvingGridSearchCV(estimator=clf, param_grid=param_grid, factor=2, random_state=rng)
gsh.fit(X, y)
gsh_time = time() - tic
tic = time()
gs = GridSearchCV(estimator=clf, param_grid=param_grid)
gs.fit(X, y)
gs_time = time() - tic
```

We now plot heatmaps for both search estimators.

```python
def make_heatmap(ax, gs, is_sh=False, make_cbar=False):
    """Helper to make a heatmap."""
    results = pd.DataFrame.from_dict(gs.cv_results_)
    results['params_str'] = results.params.apply(str)
    if is_sh:
        # SH dataframe: get mean_test_score values for the highest iter
        scores_matrix = results.sort_values('iter').pivot_table(
            index='param_gamma', columns='param_C',
            values='mean_test_score', aggfunc='last'
        )
    else:
        scores_matrix = results.pivot(index='param_gamma', columns='param_C',
                                       values='mean_test_score')

    im = ax.imshow(scores_matrix)

    ax.set_xticks(np.arange(len(Cs)))
    ax.set_xticklabels(['{:0E}'.format(x) for x in Cs])
    ax.set_xlabel('C', fontsize=15)

    ax.set_yticks(np.arange(len(gammas)))
    ax.set_yticklabels(['{:0E}'.format(x) for x in gammas])
    ax.set_ylabel('gamma', fontsize=15)

    plt.setp(ax.get_xticklabels(), rotation=45, ha="right",
```

(continues on next page)
rotation_mode="anchor")

if is_sh:
    iterations = results.pivot_table(index='param_gamma',
                                      columns='param_C', values='iter',
                                      aggfunc='max').values
    for i in range(len(gammas)):
        for j in range(len(Cs)):
            ax.text(j, i, iterations[i, j],
                    ha="center", va="center", color="w", fontsize=20)

if make_cbar:
    fig.subplots_adjust(right=0.8)
    cbar_ax = fig.add_axes([0.85, 0.15, 0.05, 0.7])
    fig.colorbar(im, cax=cbar_ax)
    cbar_ax.set_ylabel('mean_test_score', rotation=-90, va="bottom",
                       fontsize=15)

fig, axes = plt.subplots(ncols=2, sharey=True)
ax1, ax2 = axes

make_heatmap(ax1, gsh, is_sh=True)
make_heatmap(ax2, gs, make_cbar=True)

ax1.set_title('Successive Halving
              time = {:.3f}s'.format(gsh_time),
              fontsize=15)
ax2.set_title('GridSearch
              time = {:.3f}s'.format(gs_time), fontsize=15)
plt.show()
The heatmaps show the mean test score of the parameter combinations for an SVC instance. The HalvingGridSearchCV also shows the iteration at which the combinations were last used. The combinations marked as 0 were only evaluated at the first iteration, while the ones with 5 are the parameter combinations that are considered the best ones.

We can see that the HalvingGridSearchCV class is able to find parameter combinations that are just as accurate as GridSearchCV, in much less time.

**Total running time of the script:** (0 minutes 11.722 seconds)

### 6.22.16 Visualizing cross-validation behavior in scikit-learn

Choosing the right cross-validation object is a crucial part of fitting a model properly. There are many ways to split data into training and test sets in order to avoid model overfitting, to standardize the number of groups in test sets, etc. This example visualizes the behavior of several common scikit-learn objects for comparison.
Visualize our data

First, we must understand the structure of our data. It has 100 randomly generated input datapoints, 3 classes split unevenly across datapoints, and 10 “groups” split evenly across datapoints.

As we’ll see, some cross-validation objects do specific things with labeled data, others behave differently with grouped data, and others do not use this information.

To begin, we’ll visualize our data.

```python
# Generate the class/group data
n_points = 100
X = np.random.randn(100, 10)

percentiles_classes = [.1, .3, .6]
y = np.hstack([ii * int(100 * perc) for ii, perc in enumerate(percentiles_classes)])

# Evenly spaced groups repeated once
groups = np.hstack([[ii] * 10 for ii in range(10)])

def visualize_groups(classes, groups, name):
    # Visualize dataset groups
    fig, ax = plt.subplots()
    ax.scatter(range(len(groups)), [.5] * len(groups), c=groups, marker='_', lw=50, cmap=cmap_data)
    ax.scatter(range(len(groups)), [3.5] * len(groups), c=classes, marker='_', lw=50, cmap=cmap_data)
    ax.set(ylim=[-1, 5], yticks=[.5, 3.5], yticklabels=['Data\n    group', 'Data\nclass'], xlabel="Sample index")

visualize_groups(y, groups, "no groups")
```
Define a function to visualize cross-validation behavior

We’ll define a function that lets us visualize the behavior of each cross-validation object. We’ll perform 4 splits of the data. On each split, we’ll visualize the indices chosen for the training set (in blue) and the test set (in red).

```python
def plot_cv_indices(cv, X, y, group, ax, n_splits, lw=10):
    """Create a sample plot for indices of a cross-validation object.""

    # Generate the training/testing visualizations for each CV split
    for ii, (tr, tt) in enumerate(cv.split(X=X, y=y, groups=group)):
        # Fill in indices with the training/test groups
        indices = np.array([np.nan] * len(X))
        indices[tt] = 1
        indices[tr] = 0

        # Visualize the results
        ax.scatter(range(len(indices)), [ii + .5] * len(indices),
                   c=indices, marker='_', lw=lw, cmap=cmap_cv,
                   vmin=-.2, vmax=1.2)

    # Plot the data classes and groups at the end
    ax.scatter(range(len(X)), [ii + 1.5] * len(X),
               c=y, marker='_', lw=lw, cmap=cmap_data)
```

(continues on next page)
Let's see how it looks for the KFold cross-validation object:

```python
fig, ax = plt.subplots()
cv = KFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```

As you can see, by default the KFold cross-validation iterator does not take either datapoint class or group into consideration. We can change this by using the StratifiedKFold like so.
fig, ax = plt.subplots()
cv = StratifiedKFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)

Out:
<AxesSubplot:title={'center':'StratifiedKFold'}, xlabel='Sample index', ylabel='CV iteration'>

In this case, the cross-validation retained the same ratio of classes across each CV split. Next we’ll visualize this behavior for a number of CV iterators.

Visualize cross-validation indices for many CV objects

Let’s visually compare the cross validation behavior for many scikit-learn cross-validation objects. Below we will loop through several common cross-validation objects, visualizing the behavior of each.

Note how some use the group/class information while others do not.

cvs = [KFold, GroupKFold, ShuffleSplit, StratifiedKFold,
       GroupShuffleSplit, StratifiedShuffleSplit, TimeSeriesSplit]

for cv in cvs:
```python
this_cv = cv(n_splits=n_splits)
fig, ax = plt.subplots(figsize=(6, 3))
plot_cv_indices(this_cv, X, y, groups, ax, n_splits)

ax.legend([Patch(color=cmap_cv(.8)), Patch(color=cmap_cv(.02))],
           ['Testing set', 'Training set'], loc=(1.02, .8))
# Make the legend fit
plt.tight_layout()
fig.subplots_adjust(right=.7)
plt.show()
```

6.22.17 Receiver Operating Characteristic (ROC)

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

ROC curves are typically used in binary classification to study the output of a classifier. In order to extend ROC curve and ROC area to multi-label classification, it is necessary to binarize the output. One ROC curve can be drawn per label, but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Another evaluation measure for multi-label classification is macro-averaging, which gives equal weight to the classification of each label.

Note:

See also sklearn.metrics.roc_auc_score, Receiver Operating Characteristic (ROC) with cross validation

plt.show()
Plot ROC curves for the multilabel problem

Compute macro-average ROC curve and ROC area

```python
# First aggregate all false positive rates
all_fpr = np.unique(np.concatenate([fpr[i] for i in range(n_classes)]))

# Then interpolate all ROC curves at this points
mean_tpr = np.zeros_like(all_fpr)
for i in range(n_classes):
    mean_tpr += interp(all_fpr, fpr[i], tpr[i])

# Finally average it and compute AUC
mean_tpr /= n_classes

fpr["macro"] = all_fpr
tpr["macro"] = mean_tpr
roc_auc["macro"] = auc(fpr["macro"], tpr["macro"])

# Plot all ROC curves
plt.figure()
plt.plot(fpr["micro"], tpr["micro"],
         label='micro-average ROC curve (area = {0:0.2f})'.format(roc_auc["micro"]),
         (continues on next page)
```
```python
plt.plot(fpr['macro'], tpr['macro'],
         label='macro-average ROC curve (area = {0:0.2f})'
             ''.format(roc_auc['macro']),
         color='navy', linestyle=':', linewidth=4)

colors = cycle(['aqua', 'darkorange', 'cornflowerblue'])
for i, color in zip(range(n_classes), colors):
    plt.plot(fpr[i], tpr[i], color=color, lw=lw,
             label='ROC curve of class {0} (area = {1:0.2f})'
             ''.format(i, roc_auc[i]))

plt.plot([0, 1], [0, 1], 'k--', lw=lw)
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('Some extension of Receiver operating characteristic to multi-class')
plt.legend(loc='lower right')
plt.show()
```

Out:
Area under ROC for the multiclass problem

The `sklearn.metrics.roc_auc_score` function can be used for multi-class classification. The multi-class One-vs-One scheme compares every unique pairwise combination of classes. In this section, we calculate the AUC using the OvR and OvO schemes. We report a macro average, and a prevalence-weighted average.

```python
y_prob = classifier.predict_proba(X_test)

macro_roc_auc_ovo = roc_auc_score(y_test, y_prob, multi_class="ovo",
                                 average="macro")
weighted_roc_auc_ovo = roc_auc_score(y_test, y_prob, multi_class="ovo",
                                     average="weighted")
macro_roc_auc_ovr = roc_auc_score(y_test, y_prob, multi_class="ovr",
                                   average="macro")
weighted_roc_auc_ovr = roc_auc_score(y_test, y_prob, multi_class="ovr",
                                     average="weighted")

print("One-vs-One ROC AUC scores:
      {:.6f} (macro),
      {:.6f} (weighted by prevalence)".format(macro_roc_auc_ovo, weighted_roc_auc_ovo))
print("One-vs-Rest ROC AUC scores:
      {:.6f} (macro),
      {:.6f} (weighted by prevalence)".format(macro_roc_auc_ovr, weighted_roc_auc_ovr))
```

Out:

```
One-vs-One ROC AUC scores:
0.698586 (macro),
0.665839 (weighted by prevalence)
One-vs-Rest ROC AUC scores:
0.698586 (macro),
0.665839 (weighted by prevalence)
```

Total running time of the script: ( 0 minutes 0.223 seconds)

### 6.22.18 Precision-Recall

Example of Precision-Recall metric to evaluate classifier output quality.

Precision-Recall is a useful measure of success of prediction when the classes are very imbalanced. In information retrieval, precision is a measure of result relevancy, while recall is a measure of how many truly relevant results are returned.

The precision-recall curve shows the tradeoff between precision and recall for different threshold. A high area under the curve represents both high recall and high precision, where high precision relates to a low false positive rate, and high recall relates to a low false negative rate. High scores for both show that the classifier is returning accurate results (high precision), as well as returning a majority of all positive results (high recall).

A system with high recall but low precision returns many results, but most of its predicted labels are incorrect when compared to the training labels. A system with high precision but low recall is just the opposite, returning very few
results, but most of its predicted labels are correct when compared to the training labels. An ideal system with high precision and high recall will return many results, with all results labeled correctly.

Precision ($P$) is defined as the number of true positives ($T_p$) over the number of true positives plus the number of false positives ($F_p$).

$$P = \frac{T_p}{T_p + F_p}$$

Recall ($R$) is defined as the number of true positives ($T_p$) over the number of true positives plus the number of false negatives ($F_n$).

$$R = \frac{T_p}{T_p + F_n}$$

These quantities are also related to the ($F_1$) score, which is defined as the harmonic mean of precision and recall.

$$F1 = \frac{2 P \times R}{P + R}$$

Note that the precision may not decrease with recall. The definition of precision ($\frac{T_p}{T_p + F_p}$) shows that lowering the threshold of a classifier may increase the denominator, by increasing the number of results returned. If the threshold was previously set too high, the new results may all be true positives, which will increase precision. If the previous threshold was about right or too low, further lowering the threshold will introduce false positives, decreasing precision.

Recall is defined as $\frac{T_p}{T_p + F_n}$, where $T_p + F_n$ does not depend on the classifier threshold. This means that lowering the classifier threshold may increase recall, by increasing the number of true positive results. It is also possible that lowering the threshold may leave recall unchanged, while the precision fluctuates.

The relationship between recall and precision can be observed in the stairstep area of the plot - at the edges of these steps a small change in the threshold considerably reduces precision, with only a minor gain in recall.

**Average precision (AP)** summarizes such a plot as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$$AP = \sum_n (R_n - R_{n-1}) P_n$$

where $P_n$ and $R_n$ are the precision and recall at the $n$th threshold. A pair ($R_k, P_k$) is referred to as an operating point.

AP and the trapezoidal area under the operating points (sklearn.metrics.auc) are common ways to summarize a precision-recall curve that lead to different results. Read more in the User Guide.

Precision-recall curves are typically used in binary classification to study the output of a classifier. In order to extend the precision-recall curve and average precision to multi-class or multi-label classification, it is necessary to binarize the output. One curve can be drawn per label, but one can also draw a precision-recall curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

6.22. Model Selection 1425
In binary classification settings

Create simple data

Try to differentiate the two first classes of the iris data

```python
from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
import numpy as np
iris = datasets.load_iris()
X = iris.data
y = iris.target

# Add noisy features
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# Limit to the two first classes, and split into training and test
X_train, X_test, y_train, y_test = train_test_split(X[y < 2], y[y < 2],
    test_size=.5,
    random_state=random_state)

# Create a simple classifier
classifier = svm.LinearSVC(random_state=random_state)
classifier.fit(X_train, y_train)
y_score = classifier.decision_function(X_test)
```

Compute the average precision score

```python
from sklearn.metrics import average_precision_score
average_precision = average_precision_score(y_test, y_score)

print('Average precision-recall score: {0:0.2f}'.format(average_precision))

Out:
Average precision-recall score: 0.88
```

Plot the Precision-Recall curve

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import plot_precision_recall_curve
import matplotlib.pyplot as plt
disp = plot_precision_recall_curve(classifier, X_test, y_test)
disp.ax_.set_title('2-class Precision-Recall curve: 
' 'AP={0:0.2f}'.format(average_precision))
```
In multi-label settings

Create multi-label data, fit, and predict

We create a multi-label dataset, to illustrate the precision-recall in multi-label settings

```python
from sklearn.preprocessing import label_binarize

# Use label_binarize to be multi-label like settings
Y = label_binarize(y, classes=[0, 1, 2])
n_classes = Y.shape[1]

# Split into training and test
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=.5, random_state=random_state)

# We use OneVsRestClassifier for multi-label prediction
from sklearn.multiclass import OneVsRestClassifier

# Run classifier
```

(continues on next page)
The average precision score in multi-label settings

```python
from sklearn.metrics import precision_recallCurve
from sklearn.metrics import average_precision_score

# For each class
precision = dict()
recall = dict()
average_precision = dict()
for i in range(n_classes):
    precision[i], recall[i], _ = precision_recallCurve(Y_test[:, i],
                                                        y_score[:, i])
    average_precision[i] = average_precision_score(Y_test[:, i], y_score[:, i])

# A "micro-average": quantifying score on all classes jointly
precision["micro"], recall["micro"], _ = precision_recallCurve(Y_test.ravel(),
                                                                y_score.ravel())
average_precision["micro"] = average_precision_score(Y_test, y_score,
                                                        average="micro")

print('Average precision score, micro-averaged over all classes: {0:0.2f}'.format(average_precision["micro"]))
```

Out:

```
Average precision score, micro-averaged over all classes: 0.43
```

**Plot the micro-averaged Precision-Recall curve**

```python
plt.figure()
plt.step(recall['micro'], precision['micro'], where='post')
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title('Average precision score, micro-averaged over all classes: AP={0:0.2f}'.format(average_precision["micro"]))
```
Average precision score, micro-averaged over all classes: AP=0.43

Plot Precision-Recall curve for each class and iso-f1 curves

```python
from itertools import cycle

# setup plot details
colors = cycle(['navy', 'turquoise', 'darkorange', 'cornflowerblue', 'teal'])

plt.figure(figsize=(7, 8))
f_scores = np.linspace(0.2, 0.8, num=4)
lines = []
labels = []
for f_score in f_scores:
    x = np.linspace(0.01, 1)
y = f_score * x / (2 * x - f_score)
    l, = plt.plot(x[y >= 0], y[y >= 0], color='gray', alpha=0.2)
    plt.annotate('f1={0:0.1f}'.format(f_score), xy=(0.9, y[45] + 0.02))
lines.append(l)
labels.append('iso-f1 curves')
l, = plt.plot(recall['micro'], precision['micro'], color='gold', lw=2)
lines.append(l)
labels.append('micro-average Precision-recall curve (area = {0:0.2f})'.format(AUC)

plt.xlim(0.0, 1.0)
plt.ylim(0.0, 1.0)
plt.xlabel('Recall')
plt.ylabel('Precision')

6.22.19 Plotting Learning Curves

In the first column, first row the learning curve of a naive Bayes classifier is shown for the digits dataset. Note that the training score and the cross-validation score are both not very good at the end. However, the shape of the curve can be found in more complex datasets very often: the training score is very high at the beginning and decreases and the cross-validation score is very low at the beginning and increases. In the second column, first row we see the learning curve of an SVM with RBF kernel. We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples. The plots in the second row show the times required by the models to train with various sizes of training dataset. The plots in the third row show how much time was required to train the models for each training sizes.
6.22. Model Selection
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.naive_bayes import GaussianNB
from sklearn.svm import SVC
from sklearn.datasets import load_digits
from sklearn.model_selection import learning_curve
from sklearn.model_selection import ShuffleSplit

def plot_learning_curve(estimator, title, X, y, axes=None, ylim=None, cv=None, n_jobs=None, train_sizes=np.linspace(.1, 1.0, 5)):
    ""
    Generate 3 plots: the test and training learning curve, the training samples vs fit times curve, the fit times vs score curve.
    
    Parameters
    ----------
    estimator : estimator instance
        An estimator instance implementing `fit` and `predict` methods which will be cloned for each validation.
    title : str
        Title for the chart.
    X : array-like of shape (n_samples, n_features)
        Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.
    y : array-like of shape (n_samples) or (n_samples, n_features)
        Target relative to `X` for classification or regression; None for unsupervised learning.
    axes : array-like of shape (3,), default=None
        Axes to use for plotting the curves.
    ylim : tuple of shape (2,), default=None
        Defines minimum and maximum y-values plotted, e.g. (ymin, ymax).
    cv : int, cross-validation generator or an iterable, default=None
        Determines the cross-validation splitting strategy.
        Possible inputs for cv are:
        - None, to use the default 5-fold cross-validation,
        - integer, to specify the number of folds.
        - :term:`CV splitter`,
        - An iterable yielding (train, test) splits as arrays of indices.

        For integer/None inputs, if `y` is binary or multiclass, :class:`StratifiedKFold` is used. If the estimator is not a classifier or if `y` is neither binary nor multiclass, :class:`KFold` is used.

        Refer :ref:`User Guide <cross_validation>` for the various cross-validators that can be used here.
    n_jobs : int or None, default=None
        ""
Number of jobs to run in parallel.
``None`` means 1 unless in a :obj:`joblib.parallel_backend` context.
``-1`` means using all processors. See :term:`Glossary <n_jobs>`
for more details.

``train_sizes`` : array-like of shape (n_ticks,), dtype=(int, float)
Relative or absolute numbers of training examples that will be used to
generate the learning curve. If the `dtype` is float, it is regarded
as a fraction of the maximum size of the training set (that is
determined by the selected validation method), i.e. it has to be within
(0, 1]. Otherwise it is interpreted as absolute sizes of the training
sets. Note that for classification the number of samples usually have
to be big enough to contain at least one sample from each class.
(default: np.linspace(0.1, 1.0, 5))

## 6.23 Multioutput methods

Examples concerning the `sklearn.multioutput` module.

### 6.23.1 Classifier Chain

Example of using classifier chain on a multilabel dataset.

For this example we will use the `yeast` dataset which contains 2417 datapoints each with 103 features and 14 possible labels. Each data point has at least one label. As a baseline we first train a logistic regression classifier for each of the 14 labels. To evaluate the performance of these classifiers we predict on a held-out test set and calculate the jaccard score for each sample.

Next we create 10 classifier chains. Each classifier chain contains a logistic regression model for each of the 14 labels. The models in each chain are ordered randomly. In addition to the 103 features in the dataset, each model gets the predictions of the preceding models in the chain as features (note that by default at training time each model gets the
true labels as features). These additional features allow each chain to exploit correlations among the classes. The Jaccard similarity score for each chain tends to be greater than that of the set independent logistic models.

Because the models in each chain are arranged randomly there is significant variation in performance among the chains. Presumably there is an optimal ordering of the classes in a chain that will yield the best performance. However we do not know that ordering a priori. Instead we can construct an voting ensemble of classifier chains by averaging the binary predictions of the chains and apply a threshold of 0.5. The Jaccard similarity score of the ensemble is greater than that of the independent models and tends to exceed the score of each chain in the ensemble (although this is not guaranteed with randomly ordered chains).

6.24 Nearest Neighbors

Examples concerning the `sklearn.neighbors` module.

6.24.1 Nearest Neighbors regression

Demonstrate the resolution of a regression problem using a k-Nearest Neighbor and the interpolation of the target using both barycenter and constant weights.

```python
# Author: Alexandre Gramfort <alexandre.gramfort@inria.fr>
# Fabian Pedregosa <fabian.pedregosa@inria.fr>
#
# License: BSD 3 clause (C) INRIA

# # Generate sample data
import numpy as np
```

(continues on next page)
import matplotlib.pyplot as plt
from sklearn import neighbors

np.random.seed(0)
X = np.sort(5 * np.random.rand(40, 1), axis=0)
T = np.linspace(0, 5, 500)[:, np.newaxis]
y = np.sin(X).ravel()

# Add noise to targets
y[::5] += 1 * (0.5 - np.random.rand(8))

# Fit regression model
n_neighbors = 5
for i, weights in enumerate(['uniform', 'distance'])�
    knn = neighbors.KNeighborsRegressor(n_neighbors, weights=weights)
y_ = knn.fit(X, y).predict(T)

    plt.subplot(2, 1, i + 1)
    plt.scatter(X, y, color='darkorange', label='data')
    plt.plot(T, y_, color='navy', label='prediction')
    plt.axis('tight')
    plt.legend()
    plt.title("KNeighborsRegressor (k = %i, weights = '%s')" % (n_neighbors, weights))

plt.tight_layout()
plt.show()

Total running time of the script: ( 0 minutes 0.194 seconds)

6.24.2 Outlier detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for outlier detection which is the default use case of this estimator in scikit-learn. Note that when LOF is used for outlier detection it has no predict, decision_function and score_samples methods. See User Guide: for details on the difference between outlier detection and novelty detection and how to use LOF for novelty detection.

The number of neighbors considered (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.
import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

# Generate train data
X_inliers = 0.3 * np.random.randn(100, 2)
X_inliers = np.r_[X_inliers + 2, X_inliers - 2]

# Generate some outliers
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))
X = np.r_[X_inliers, X_outliers]
n_outliers = len(X_outliers)
ground_truth = np.ones(len(X), dtype=int)
ground_truth[-n_outliers:] = -1

# fit the model for outlier detection (default)
clf = LocalOutlierFactor(n_neighbors=20, contamination=0.1)
# use fit_predict to compute the predicted labels of the training samples
# (when LOF is used for outlier detection, the estimator has no predict,
# decision_function and score_samples methods).

6.24. Nearest Neighbors
y_pred = clf.fit_predict(X)
n_errors = (y_pred != ground_truth).sum()
X_scores = clf.negative_outlier_factor_

plt.title("Local Outlier Factor (LOF)")
plt.scatter(X[:, 0], X[:, 1], color='k', s=3., label='Data points')
# plot circles with radius proportional to the outlier scores
radius = (X_scores.max() - X_scores) / (X_scores.max() - X_scores.min())
plt.scatter(X[:, 0], X[:, 1], s=1000 * radius, edgecolors='r',
            facecolors='none', label='Outlier scores')
plt.axis('tight')
plt.xlim((-5, 5))

### 6.24.6 Caching nearest neighbors

This examples demonstrates how to precompute the k nearest neighbors before using them in KNeighborsClassifier. KNeighborsClassifier can compute the nearest neighbors internally, but precomputing them can have several benefits, such as finer parameter control, caching for multiple use, or custom implementations.

Here we use the caching property of pipelines to cache the nearest neighbors graph between multiple fits of KNeighborsClassifier. The first call is slow since it computes the neighbors graph, while subsequent call are faster as they do not need to recompute the graph. Here the durations are small since the dataset is small, but the gain can be more substantial when the dataset grows larger, or when the grid of parameter to search is large.
from sklearn.neighbors import KNeighborsTransformer, KNeighborsClassifier
from sklearn.model_selection import GridSearchCV
from sklearn.datasets import load_digits
from sklearn.pipeline import Pipeline

X, y = load_digits(return_X_y=True)
n_neighbors_list = [1, 2, 3, 4, 5, 6, 7, 8, 9]

# The transformer computes the nearest neighbors graph using the maximum number
# of neighbors necessary in the grid search. The classifier model filters the
# nearest neighbors graph as required by its own n_neighbors parameter.
graph_model = KNeighborsTransformer(n_neighbors=max(n_neighbors_list),
    mode='distance')
classifier_model = KNeighborsClassifier(metric='precomputed')

# Note that we give 'memory' a directory to cache the graph computation
# that will be used several times when tuning the hyperparameters of the
# classifier.

with TemporaryDirectory(prefix="sklearn_graph_cache_") as tmpdir:
    full_model = Pipeline(
        steps=[('graph', graph_model), ('classifier', classifier_model)],
        memory=tmpdir)

    param_grid = {'classifier__n_neighbors': n_neighbors_list}
grid_model = GridSearchCV(full_model, param_grid)
grid_model.fit(X, y)

# Plot the results of the grid search.
fig, axes = plt.subplots(1, 2, figsize=(8, 4))
axes[0].errorbar(x=n_neighbors_list,
                y=grid_model.cv_results_['mean_test_score'],
                yerr=grid_model.cv_results_['std_test_score'])
axes[0].set(xlabel='n_neighbors', title='Classification accuracy')
axes[1].errorbar(x=n_neighbors_list, y=grid_model.cv_results_['mean_fit_time'],
                yerr=grid_model.cv_results_['std_fit_time'], color='r')
axes[1].set(xlabel='n_neighbors', title='Fit time (with caching)')
fig.tight_layout()
plt.show()

Total running time of the script: ( 0 minutes 1.827 seconds)

### 6.24.7 Neighborhood Components Analysis Illustration

This example illustrates a learned distance metric that maximizes the nearest neighbors classification accuracy. It provides a visual representation of this metric compared to the original point space. Please refer to the User Guide for more information.

```python
# License: BSD 3 clause

import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_classification
from sklearn.neighbors import NeighborhoodComponentsAnalysis
from matplotlib import cm
from scipy.special import logsumexp

print(__doc__)

Original points

First we create a data set of 9 samples from 3 classes, and plot the points in the original space. For this example, we focus on the classification of point no. 3. The thickness of a link between point no. 3 and another point is proportional to their distance.

```numpy
X, y = make_classification(n_samples=9, n_features=2, n_informative=2,
                           n_redundant=0, n_classes=3, n_clusters_per_class=1, 
                           class_sep=1.0, random_state=0)
```n
```python
plt.figure(1)
ax = plt.gca()
for i in range(X.shape[0]):
    ax.text(X[i, 0], X[i, 1], str(i), va='center', ha='center')
    ax.scatter(X[i, 0], X[i, 1], s=300, c=cm.Set1(y[i]), alpha=0.4)

ax.set_title("Original points")
ax.axes.get_xaxis().set_visible(False)
ax.axes.get_yaxis().set_visible(False)
ax.axis('equal')  # so that boundaries are displayed correctly as circles

def link_thickness_i(X, i):
```

(continues on next page)
diff_embedded = X[i] - X
dist_embedded = np.einsum('ij,ij->i', diff_embedded,
                          diff_embedded)
dist_embedded[i] = np.inf

# compute exponentiated distances (use the log-sum-exp trick to
# avoid numerical instabilities
exp_dist_embedded = np.exp(-dist_embedded -
                          logsumexp(-dist_embedded))
return exp_dist_embedded

def relate_point(X, i, ax):
    pt_i = X[i]
    for j, pt_j in enumerate(X):
        thickness = link_thickness_i(X, i)
        if i != j:
            line = ([pt_i[0], pt_j[0]], [pt_i[1], pt_j[1]])
            ax.plot(*line, c=cm.Set1(y[j]),
                    linewidth=5*thickness[j])

i = 3
relate_point(X, i, ax)
plt.show()
Learning an embedding

We use \texttt{NeighborhoodComponentsAnalysis} to learn an embedding and plot the points after the transformation. We then take the embedding and find the nearest neighbors.

```python
nca = NeighborhoodComponentsAnalysis(max_iter=30, random_state=0)
nca = nca.fit(X, y)
plt.figure(2)
ax2 = plt.gca()
X_embedded = nca.transform(X)
relate_point(X_embedded, i, ax2)

for i in range(len(X)):
    ax2.text(X_embedded[i, 0], X_embedded[i, 1], str(i), va='center', ha='center')
    ax2.scatter(X_embedded[i, 0], X_embedded[i, 1], s=300, c=cm.Set1(y[[i]]), alpha=0.4)

ax2.set_title("NCA embedding")
ax2.axes.get_xaxis().set_visible(False)
ax2.axes.get_yaxis().set_visible(False)
ax2.axis('equal')
plt.show()
```

Total running time of the script: 0 minutes 0.232 seconds
6.24.8 Novelty detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for novelty detection. Note that when LOF is used for novelty detection you MUST not use predict, decision_function and score_samples on the training set as this would lead to wrong results. You must only use these methods on new unseen data (which are not in the training set). See User Guide: for details on the difference between outlier detection and novelty detection and how to use LOF for outlier detection.

The number of neighbors considered, (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.

![Novelty Detection with LOF](image)

import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

xx, yy = np.meshgrid(np.linspace(-5, 5, 500), np.linspace(-5, 5, 500))

6.24.9 Comparing Nearest Neighbors with and without Neighborhood Components Analysis

An example comparing nearest neighbors classification with and without Neighborhood Components Analysis.

It will plot the class decision boundaries given by a Nearest Neighbors classifier when using the Euclidean distance on the original features, versus using the Euclidean distance after the transformation learned by Neighborhood Components Analysis. The latter aims to find a linear transformation that maximises the (stochastic) nearest neighbor classification accuracy on the training set.

6.24.10 Dimensionality Reduction with Neighborhood Components Analysis

Sample usage of Neighborhood Components Analysis for dimensionality reduction.

This example compares different (linear) dimensionality reduction methods applied on the Digits data set. The data set contains images of digits from 0 to 9 with approximately 180 samples of each class. Each image is of dimension 8x8 = 64, and is reduced to a two-dimensional data point.

Principal Component Analysis (PCA) applied to this data identifies the combination of attributes (principal components, or directions in the feature space) that account for the most variance in the data. Here we plot the different samples on the 2 first principal components.

Linear Discriminant Analysis (LDA) tries to identify attributes that account for the most variance between classes. In particular, LDA, in contrast to PCA, is a supervised method, using known class labels.

Neighborhood Components Analysis (NCA) tries to find a feature space such that a stochastic nearest neighbor algorithm will give the best accuracy. Like LDA, it is a supervised method.

One can see that NCA enforces a clustering of the data that is visually meaningful despite the large reduction in dimension.
PCA, KNN (k=3)
Test accuracy = 0.52
LDA, KNN (k=3)
Test accuracy = 0.56

6.24.11 Kernel Density Estimate of Species Distributions

This shows an example of a neighbors-based query (in particular a kernel density estimate) on geospatial data, using a Ball Tree built upon the Haversine distance metric – i.e., distances over points in latitude/longitude. The dataset is provided by Phillips et. al. (2006). If available, the example uses basemap to plot the coast lines and national boundaries of South America.

This example does not perform any learning over the data (see Species distribution modeling for an example of classification based on the attributes in this dataset). It simply shows the kernel density estimate of observed data points in geospatial coordinates.

The two species are:

- “Bradypus variegatus”, the Brown-throated Sloth.
- “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

### 6.24.12 Simple 1D Kernel Density Estimation

This example uses the `KernelDensity` class to demonstrate the principles of Kernel Density Estimation in one dimension.

The first plot shows one of the problems with using histograms to visualize the density of points in 1D. Intuitively, a histogram can be thought of as a scheme in which a unit “block” is stacked above each point on a regular grid. As the top two panels show, however, the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution. If we instead center each block on the point it represents, we get the estimate shown in the bottom left panel. This is a kernel density estimation with a “top hat” kernel. This idea can be generalized to other kernel shapes: the bottom-right panel of the first figure shows a Gaussian kernel density estimate over the same distribution.

Scikit-learn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure, through the `KernelDensity` estimator. The available kernels are shown in the second figure of this example.

The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension. Though this example uses 1D distributions, kernel density estimation is easily and efficiently extensible to higher dimensions as well.
Available Kernels

gaussian

tophat

epanechnikov

exponential

linear

cosine

6.24.13 Approximate nearest neighbors in TSNE

This example presents how to chain KNeighborsTransformer and TSNE in a pipeline. It also shows how to wrap the packages annoy and nmslib to replace KNeighborsTransformer and perform approximate nearest neighbors. These packages can be installed with pip install annoy nmslib.

Note: Currently TSNE(metric='precomputed') does not modify the precomputed distances, and thus assumes that precomputed euclidean distances are squared. In future versions, a parameter in TSNE will control the optional squaring of precomputed distances (see #12401).

Note: In KNeighborsTransformer we use the definition which includes each training point as its own neighbor.
in the count of \texttt{n\_neighbors}, and for compatibility reasons, one extra neighbor is computed when \texttt{mode} == 'distance'. Please note that we do the same in the proposed wrappers.

Sample output:

6.25 Neural Networks

Examples concerning the `sklearn.neural_network` module.

6.25.1 Visualization of MLP weights on MNIST

Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior. For example if weights look unstructured, maybe some were not used at all, or if very large coefficients exist, maybe regularization was too low or the learning rate too high.

This example shows how to plot some of the first layer weights in a `MLPClassifier` trained on the MNIST dataset.

The input data consists of 28x28 pixel handwritten digits, leading to 784 features in the dataset. Therefore the first layer weight matrix have the shape (784, hidden_layer_sizes[0]). We can therefore visualize a single column of the weight matrix as a 28x28 pixel image.

To make the example run faster, we use very few hidden units, and train only for a very short time. Training longer would result in weights with a much smoother spatial appearance. The example will throw a warning because it doesn’t converge, in this case this is what we want because of CI’s time constraints.

6.25.2 Restricted Boltzmann Machine features for digit classification

For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background, like handwritten digit recognition, the Bernoulli Restricted Boltzmann machine model (BernoulliRBM) can perform effective non-linear feature extraction.

In order to learn good latent representations from a small dataset, we artificially generate more labeled data by perturbing the training data with linear shifts of 1 pixel in each direction.

This example shows how to build a classification pipeline with a BernoulliRBM feature extractor and a LogisticRegression classifier. The hyperparameters of the entire model (learning rate, hidden layer size, regularization) were optimized by grid search, but the search is not reproduced here because of runtime constraints.

Logistic regression on raw pixel values is presented for comparison. The example shows that the features extracted by the BernoulliRBM help improve the classification accuracy.

6.25.3 Compare Stochastic learning strategies for MLPClassifier

This example visualizes some training loss curves for different stochastic learning strategies, including SGD and
Adam. Because of time-constraints, we use several small datasets, for which L-BFGS might be more suitable. The
general trend shown in these examples seems to carry over to larger datasets, however.

Note that those results can be highly dependent on the value of learning_rate_init.

6.25.4 Varying regularization in Multi-layer Perceptron

A comparison of different values for regularization parameter ‘alpha’ on synthetic datasets. The plot shows that different alphas yield different decision functions.

Alpha is a parameter for regularization term, aka penalty term, that combats overfitting by constraining the size of the weights. Increasing alpha may fix high variance (a sign of overfitting) by encouraging smaller weights, resulting in a decision boundary plot that appears with lesser curvatures. Similarly, decreasing alpha may fix high bias (a sign of underfitting) by encouraging larger weights, potentially resulting in a more complicated decision boundary.

6.26 Pipelines and composite estimators

Examples of how to compose transformers and pipelines from other estimators. See the User Guide.

6.26.1 Concatenating multiple feature extraction methods

In many real-world examples, there are many ways to extract features from a dataset. Often it is beneficial to combine several methods to obtain good performance. This example shows how to use FeatureUnion to combine features obtained by PCA and univariate selection.

Combining features using this transformer has the benefit that it allows cross validation and grid searches over the whole process.

The combination used in this example is not particularly helpful on this dataset and is only used to illustrate the usage of FeatureUnion.

Out:

```
Combined space has 3 features
Fitting 5 folds for each of 18 candidates, totalling 90 fits
[CV 1/5; 1/18] START features__pca__n_components=1, features__univ_select__k=1, svm__

6.26.3 Selecting dimensionality reduction with Pipeline and GridSearchCV

This example constructs a pipeline that does dimensionality reduction followed by prediction with a support vector classifier. It demonstrates the use of GridSearchCV and Pipeline to optimize over different classes of estimators in a single CV run – unsupervised PCA and NMF dimensionality reductions are compared to univariate feature selection during the grid search.

Additionally, Pipeline can be instantiated with the memory argument to memoize the transformers within the pipeline, avoiding to fit again the same transformers over and over.

Note that the use of memory to enable caching becomes interesting when the fitting of a transformer is costly.

# %%% Illustration of Pipeline and GridSearchCV

This section illustrates the use of a Pipeline with GridSearchCV

# Authors: Robert McGibbon, Joel Nothman, Guillaume Lemaitre

gap = Pipeline([# the reduce_dim stage is populated by the param_grid
    ('reduce_dim', 'passthrough'),
    ('classify', LinearSVC(dual=False, max_iter=10000))])

N_FEATURES_OPTIONS = [2, 4, 8]
C_OPTIONS = [1, 10, 100, 1000]
param_grid = [
    {'reduce_dim': [PCA(iterated_power=7), NMF()]},
    {'reduce_dim__n_components': N_FEATURES_OPTIONS,
     'classify__C': C_OPTIONS}
]
}

(continues on next page)
```python
'classify__C': C_OPTIONS,
]
reducer_labels = ['PCA', 'NMF', 'KBest(chi2)']

grid = GridSearchCV(pipe, n_jobs=1, param_grid=param_grid)
X, y = load_digits(return_X_y=True)
grid.fit(X, y)

mean_scores = np.array(grid.cv_results_['mean_test_score'])
# scores are in the order of param_grid iteration, which is alphabetical
mean_scores = mean_scores.reshape(len(C_OPTIONS), -1, len(N_FEATURES_OPTIONS))
# select score for best C
mean_scores = mean_scores.max(axis=0)
bar_offsets = (np.arange(len(N_FEATURES_OPTIONS)) *
    (len(reducer_labels) + 1) + .5)

plt.figure()
COLORS = 'bgrcmyk'
for i, (label, reducer_scores) in enumerate(zip(reducer_labels, mean_scores)):
    plt.bar(bar_offsets + i, reducer_scores, label=label, color=COLORS[i])
plt.title("Comparing feature reduction techniques")
plt.xlabel('Reduced number of features')
plt.xticks(bar_offsets + len(reducer_labels) / 2, N_FEATURES_OPTIONS)
plt.ylabel('Digit classification accuracy')
plt.ylim((0, 1))
plt.legend(loc='upper left')
plt.show()
```
Caching transformers within a Pipeline

It is sometimes worthwhile storing the state of a specific transformer since it could be used again. Using a pipeline in GridSearchCV triggers such situations. Therefore, we use the argument memory to enable caching.

**Warning:** Note that this example is, however, only an illustration since for this specific case fitting PCA is not necessarily slower than loading the cache. Hence, use the memory constructor parameter when the fitting of a transformer is costly.

```python
from joblib import Memory
from shutil import rmtree

# Create a temporary folder to store the transformers of the pipeline
location = 'cachedir'
memory = Memory(location=location, verbose=10)
cached_pipe = Pipeline([('reduce_dim', PCA()),
                        ('classify', LinearSVC(dual=False, max_iter=10000))],
                        memory=memory)

# This time, a cached pipeline will be used within the grid search
```

(continues on next page)
The PCA fitting is only computed at the evaluation of the first configuration of the C parameter of the LinearSVC classifier. The other configurations of C will trigger the loading of the cached PCA estimator data, leading to savings in processing time. Therefore, the use of caching the pipeline using memory is highly beneficial when fitting a transformer is costly.

Total running time of the script: 0 minutes 5.242 seconds

### 6.26.4 Column Transformer with Mixed Types

This example illustrates how to apply different preprocessing and feature extraction pipelines to different subsets of features, using ColumnTransformer. This is particularly handy for the case of datasets that contain heterogeneous data types, since we may want to scale the numeric features and one-hot encode the categorical ones.

In this example, the numeric data is standard-scaled after mean-imputation, while the categorical data is one-hot encoded after imputing missing values with a new category ('missing').

In addition, we show two different ways to dispatch the columns to the particular pre-processor: by column names and by column data types.

Finally, the preprocessing pipeline is integrated in a full prediction pipeline using Pipeline, together with a simple classification model.

```python
# Author: Pedro Morales <part.morales@gmail.com>
#
# License: BSD 3 clause

import numpy as np
from sklearn.compose import ColumnTransformer
from sklearn.datasets import fetch_openml
from sklearn.pipeline import Pipeline
from sklearn.impute import SimpleImputer
from sklearn.preprocessing import StandardScaler, OneHotEncoder
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split, GridSearchCV

np.random.seed(0)

# Load data from https://www.openml.org/d/40945
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)

# Alternatively X and y can be obtained directly from the frame attribute:
# X = titanic.frame.drop('survived', axis=1)
# y = titanic.frame['survived']
```
Use **ColumnTransformer** by selecting column by names

We will train our classifier with the following features:

**Numeric Features:**
- age: float;
- fare: float.

**Categorical Features:**
- embarked: categories encoded as strings { 'C', 'S', 'Q' };
- sex: categories encoded as strings { 'female', 'male' };
- pclass: ordinal integers (1, 2, 3).

We create the preprocessing pipelines for both numeric and categorical data. Note that pclass could either be treated as a categorical or numeric feature.

```python
numeric_features = ['age', 'fare']
numeric_transformer = Pipeline(steps=[
    ('imputer', SimpleImputer(strategy='median')),
    ('scaler', StandardScaler())])
categorical_features = ['embarked', 'sex', 'pclass']
categorical_transformer = OneHotEncoder(handle_unknown='ignore')
preprocessor = ColumnTransformer(
    transformers=[
        ('num', numeric_transformer, numeric_features),
        ('cat', categorical_transformer, categorical_features)])

# Append classifier to preprocessing pipeline.
# Now we have a full prediction pipeline.
clf = Pipeline(steps=[
    ('preprocessor', preprocessor),
    ('classifier', LogisticRegression())])

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2,
                                        random_state=0)
clf.fit(X_train, y_train)

print("model score: \%3f" % clf.score(X_test, y_test))
```

Out:

```
model score: 0.790
```

**HTML representation of Pipeline**

When the `Pipeline` is printed out in a Jupyter notebook an HTML representation of the estimator is displayed as follows:

```python
from sklearn import set_config
set_config(display='diagram')
clf
```
Use **ColumnTransformer** by selecting column by data types

When dealing with a cleaned dataset, the preprocessing can be automatic by using the data types of the column to decide whether to treat a column as a numerical or categorical feature. `sklearn.compose.make_column_selector` gives this possibility. First, let’s only select a subset of columns to simplify our example.

```python
subset_feature = ['embarked', 'sex', 'pclass', 'age', 'fare']
X_train, X_test = X_train[subset_feature], X_test[subset_feature]
```

Then, we introspect the information regarding each column data type.

```python
X_train.info()
```

Out:

```
<class 'pandas.core.frame.DataFrame'>
Int64Index: 1047 entries, 1118 to 684
Data columns (total 5 columns):
# Column   Non-Null Count   Dtype
--- ------ -------------- -----  
 0 embarked 1045 non-null   category
 1 sex 1047 non-null   category
 2 pclass 1047 non-null    float64
 3 age 841 non-null   float64
 4 fare 1046 non-null    float64
dtypes: category(2), float64(3)
memory usage: 35.0 KB
```

We can observe that the `embarked` and `sex` columns were tagged as `category` columns when loading the data with `fetch_openml`. Therefore, we can use this information to dispatch the categorical columns to the `categorical_transformer` and the remaining columns to the `numerical_transformer`.

**Note:** In practice, you will have to handle yourself the column data type. If you want some columns to be considered as `category`, you will have to convert them into categorical columns. If you are using pandas, you can refer to their documentation regarding Categorical data.

```python
from sklearn.compose import make_column_selector as selector
preprocessor = ColumnTransformer(transformers=[
    ('num', numeric_transformer, selector(dtype_exclude="category")),
    ('cat', categorical_transformer, selector(dtype_include="category"))
])
clf = Pipeline(steps=[
    ('preprocessor', preprocessor),
    ('classifier', LogisticRegression())
])
clf.fit(X_train, y_train)
print("model score: %.3f" % clf.score(X_test, y_test))
```

Out:

```
model score: 0.794
```

The resulting score is not exactly the same as the one from the previous pipeline because the dtype-based selector treats the `pclass` columns as a numeric feature instead of a categorical feature as previously:
Using the prediction pipeline in a grid search

Grid search can also be performed on the different preprocessing steps defined in the ColumnTransformer object, together with the classifier's hyperparameters as part of the Pipeline. We will search for both the imputer strategy of the numeric preprocessing and the regularization parameter of the logistic regression using GridSearchCV.

```python
param_grid = {
    'preprocessor__num__imputer__strategy': ['mean', 'median'],
    'classifier__C': [0.1, 1.0, 10, 100],
}
grid_search = GridSearchCV(clf, param_grid, cv=10)
grid_search
```

Calling `fit` triggers the cross-validated search for the best hyper-parameters combination:

```python
grid_search.fit(X_train, y_train)
print(f"Best params:")
print(grid_search.best_params_)
```

Out:

```
Best params:
{'classifier__C': 0.1, 'preprocessor__num__imputer__strategy': 'mean'}
```

The internal cross-validation scores obtained by those parameters is:

```python
print(f"Internal CV score: {grid_search.best_score_:3f}\n")
```

Out:

```
Internal CV score: 0.784
```

We can also introspect the top grid search results as a pandas dataframe:

```python
import pandas as pd

cv_results = pd.DataFrame(grid_search.cv_results_)
cv_results = cv_results.sort_values("mean_test_score", ascending=False)
cv_results["mean_test_score", "std_test_score",
          "param_preprocessor__num__imputer__strategy",
          (continues on next page)
```
The best hyper-parameters have been used to re-fit a final model on the full training set. We can evaluate that final model on held-out test data that was not used for hyperparameter tuning.

```
print(('best logistic regression from grid search: %.3f
      ' % grid_search.score(X_test, y_test)))
```

Out:

```
best logistic regression from grid search: 0.794
```

Total running time of the script: ( 0 minutes 2.322 seconds)

### 6.26.5 Column Transformer with Heterogeneous Data Sources

Datasets can often contain components that require different feature extraction and processing pipelines. This scenario might occur when:

1. your dataset consists of heterogeneous data types (e.g. raster images and text captions),
2. your dataset is stored in a pandas.DataFrame and different columns require different processing pipelines.

This example demonstrates how to use ColumnTransformer on a dataset containing different types of features. The choice of features is not particularly helpful, but serves to illustrate the technique.

```python
# Author: Matt Terry <matt.terry@gmail.com>
#
# License: BSD 3 clause

import numpy as np

from sklearn.preprocessing import FunctionTransformer
from sklearn.datasets import fetch_20newsgroups
from sklearn.decomposition import TruncatedSVD
from sklearn.feature_extraction import DictVectorizer
from sklearn.feature_extraction.text import TfidfVectorizer
from sklearn.metrics import classification_report
from sklearn.pipeline import Pipeline
from sklearn.compose import ColumnTransformer
from sklearn.svm import LinearSVC

20 newsgroups dataset

We will use the 20 newsgroups dataset, which comprises posts from newsgroups on 20 topics. This dataset is split into train and test subsets based on messages posted before and after a specific date. We will only use posts from 2 categories to speed up running time.

```python
categories = ['sci.med', 'sci.space']
X_train, y_train = fetch_20newsgroups(random_state=1,
                                      subset='train',
                                      categories=categories,
                                      remove=('footers', 'quotes'),
                                      )
```
return_X_y=True)
X_test, y_test = fetch_20newsgroups(random_state=1,
    subset='test',
    categories=categories,
    remove=('footers', 'quotes'),
    return_X_y=True)

Each feature comprises meta information about that post, such as the subject, and the body of the news post.

print(X_train[0])

Out:

From: mccall@mksol.dseg.ti.com (fred j mccall 575-3539)
Subject: Re: Metric vs English
Organization: Texas Instruments Inc
Lines: 31

American, perhaps, but nothing military about it. I learned (mostly) slugs when we talked English units in high school physics and while the teacher was an ex-Navy fighter jock the book certainly wasn't produced by the military.

[Poundals were just too flinking small and made the math come out funny; sort of the same reason proponents of SI give for using that.]

--
"Insisting on perfect safety is for people who don't have the balls to live in the real world." -- Mary Shafer, NASA Ames Dryden

Creating transformers

First, we would like a transformer that extracts the subject and body of each post. Since this is a stateless transformation (does not require state information from training data), we can define a function that performs the data transformation then use `FunctionTransformer` to create a scikit-learn transformer.

```python
def subject_body_extractor(posts):
    # construct object dtype array with two columns
    # first column = 'subject' and second column = 'body'
    features = np.empty(shape=(len(posts), 2), dtype=object)
    for i, text in enumerate(posts):
        # temporary variable `_` stores '\n\n'
        headers, _, body = text.partition('\n\n')
        # store body text in second column
        features[i, 1] = body
        prefix = 'Subject:
        sub = '
        # save text after 'Subject:' in first column
        for line in headers.split('\n'):
            if line.startswith(prefix):
```
subject_body_transformer = FunctionTransformer(subject_body_extractor)

We will also create a transformer that extracts the length of the text and the number of sentences.

def text_stats(posts):
    return [{'length': len(text),
             'num_sentences': text.count('.')}  
            for text in posts]

text_stats_transformer = FunctionTransformer(text_stats)

Classification pipeline

The pipeline below extracts the subject and body from each post using SubjectBodyExtractor, producing a (n_samples, 2) array. This array is then used to compute standard bag-of-words features for the subject and body as well as text length and number of sentences on the body, using ColumnTransformer. We combine them, with weights, then train a classifier on the combined set of features.

pipeline = Pipeline([  
    # Extract subject & body
    ('subjectbody', subject_body_transformer),  
    # Use ColumnTransformer to combine the subject and body features
    ('union', ColumnTransformer([  
        # bag-of-words for subject (col 0)
        ('subject', TfidfVectorizer(min_df=50), 0),
        # bag-of-words with decomposition for body (col 1)
        ('body_bow', Pipeline([  
            ('tfidf', TfidfVectorizer()),
            ('best', TruncatedSVD(n_components=50)),
        ]), 1),
        # Pipeline for pulling text stats from post's body
        ('body_stats', Pipeline([  
            ('stats', text_stats_transformer),  
            ('vect', DictVectorizer()),  
        ]), 1),
    ]),
    # weight above ColumnTransformer features
    transformer_weights={
        'subject': 0.8,
        'body_bow': 0.5,
        'body_stats': 1.0,
    },
    # Use a SVC classifier on the combined features
    ('svc', LinearSVC(dual=False)),
], verbose=True)
Finally, we fit our pipeline on the training data and use it to predict topics for \(X_{test}\). Performance metrics of our pipeline are then printed.

\[
pipeline.fit(X_{train}, y_{train})
\]
\[
y_{pred} = pipeline.predict(X_{test})
\]
\[
print('Classification report:

{format{
    classification_report(y_{test}, y_{pred})
})
\]

Out:

```

### 6.26.6 Effect of transforming the targets in regression model

In this example, we give an overview of `TransformedTargetRegressor`. We use two examples to illustrate the benefit of transforming the targets before learning a linear regression model. The first example uses synthetic data while the second example is based on the Ames housing data set.

```
# Author: Guillaume Lemaitre <guillaume.lemaitre@inria.fr>
# License: BSD 3 clause

import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from sklearn.datasets import make_regression
from sklearn.model_selection import train_test_split
from sklearn.linear_model import RidgeCV
from sklearn.compose import TransformedTargetRegressor
from sklearn.metrics import median_absolute_error, r2_score
from sklearn.utils.fixes import parse_version
```
A synthetic random regression dataset is generated. The targets \( y \) are modified by:

1. translating all targets such that all entries are non-negative (by adding the absolute value of the lowest \( y \)) and
2. applying an exponential function to obtain non-linear targets which cannot be fitted using a simple linear model.

Therefore, a logarithmic (\( \text{np.log1p} \)) and an exponential function (\( \text{np.expm1} \)) will be used to transform the targets before training a linear regression model and using it for prediction.

```python
X, y = make_regression(n_samples=10000, noise=100, random_state=0)
y = np.expm1((y + abs(y.min())) / 200)
y_trans = np.log1p(y)
```

Below we plot the probability density functions of the target before and after applying the logarithmic functions.

```python
f, (ax0, ax1) = plt.subplots(1, 2)
ax0.hist(y, bins=100, **density_param)
ax0.set_xlim([0, 2000])
ax0.set_ylabel('Probability')
ax0.set_xlabel('Target')
ax0.set_title('Target distribution')

ax1.hist(y_trans, bins=100, **density_param)
ax1.set_ylabel('Probability')
ax1.set_xlabel('Target')
ax1.set_title('Transformed target distribution')

f.suptitle("Synthetic data", y=0.06, x=0.53)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])
```

```python
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
```
At first, a linear model will be applied on the original targets. Due to the non-linearity, the model trained will not be precise during prediction. Subsequently, a logarithmic function is used to linearize the targets, allowing better prediction even with a similar linear model as reported by the median absolute error (MAE).

```python
def (ax0, ax1) = plt.subplots(1, 2, sharey=True)
# Use linear model
regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)
# Plot results
ax0.scatter(y_test, y_pred)
ax0.plot([0, 2000], [0, 2000], '--k')
ax0.set_ylabel('Target predicted')
ax0.set_xlabel('True Target')
ax0.set_title('Ridge regression
without target transformation')

Real-world data set

In a similar manner, the Ames housing data set is used to show the impact of transforming the targets before learning a model. In this example, the target to be predicted is the selling price of each house.

```python
from sklearn.datasets import fetch_openml
from sklearn.preprocessing import QuantileTransformer, quantile_transform
ames = fetch_openml(name="house_prices", as_frame=True)
# Keep only numeric columns
```
A `QuantileTransformer` is used to normalize the target distribution before applying a `RidgeCV` model.
The effect of the transformer is weaker than on the synthetic data. However, the transformation results in an increase in $R^2$ and large decrease of the MAE. The residual plot (predicted target - true target vs predicted target) without target transformation takes on a curved, ‘reverse smile’ shape due to residual values that vary depending on the value of predicted target. With target transformation, the shape is more linear indicating better model fit.

```
f, (ax0, ax1) = plt.subplots(2, 2, sharey='row', figsize=(6.5, 8))
regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)
ax0[0].scatter(y_pred, y_test, s=8)
ax0[0].plot([0, 7e5], [0, 7e5], '--k')

Examples concerning the `sklearn.preprocessing` module.

6.27.1 Using KBinsDiscretizer to discretize continuous features

The example compares prediction result of linear regression (linear model) and decision tree (tree based model) with and without discretization of real-valued features.

As is shown in the result before discretization, linear model is fast to build and relatively straightforward to interpret, but can only model linear relationships, while decision tree can build a much more complex model of the data. One way to make linear model more powerful on continuous data is to use discretization (also known as binning). In the example, we discretize the feature and one-hot encode the transformed data. Note that if the bins are not reasonably wide, there would appear to be a substantially increased risk of overfitting, so the discretizer parameters should usually be tuned under cross validation.

After discretization, linear regression and decision tree make exactly the same prediction. As features are constant within each bin, any model must predict the same value for all points within a bin. Compared with the result before discretization, linear model become much more flexible while decision tree gets much less flexible. Note that binning features generally has no beneficial effect for tree-based models, as these models can learn to split up the data anywhere.

6.27.2 Demonstrating the different strategies of KBinsDiscretizer

This example presents the different strategies implemented in KBinsDiscretizer:

- **'uniform'**: The discretization is uniform in each feature, which means that the bin widths are constant in each dimension.
- **'quantile'**: The discretization is done on the quantiled values, which means that each bin has approximately the same number of samples.
- **'kmeans'**: The discretization is based on the centroids of a KMeans clustering procedure.

The plot shows the regions where the discretized encoding is constant.
import numpy as np

6.27.3 Importance of Feature Scaling

Feature scaling through standardization (or Z-score normalization) can be an important preprocessing step for many machine learning algorithms. Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one.

While many algorithms (such as SVM, K-nearest neighbors, and logistic regression) require features to be normalized, intuitively we can think of Principle Component Analysis (PCA) as being a prime example of when normalization is important. In PCA we are interested in the components that maximize the variance. If one component (e.g. human height) varies less than another (e.g. weight) because of their respective scales (meters vs. kilos), PCA might determine that the direction of maximal variance more closely corresponds with the ‘weight’ axis, if those features are not scaled. As a change in height of one meter can be considered much more important than the change in weight of one kilogram, this is clearly incorrect.

To illustrate this, PCA is performed comparing the use of data with `StandardScaler` applied, to unscaled data. The results are visualized and a clear difference noted. The 1st principal component in the unscaled set can be seen. It can be seen that feature #13 dominates the direction, being a whole two orders of magnitude above the other features. This is contrasted when observing the principal component for the scaled version of the data. In the scaled version, the orders of magnitude are roughly the same across all the features.

The dataset used is the Wine Dataset available at UCI. This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure (i.e alcohol content, and malic acid).

The transformed data is then used to train a naïve Bayes classifier, and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version.

6.27.4 Map data to a normal distribution

This example demonstrates the use of the Box-Cox and Yeo-Johnson transforms through `PowerTransformer` to map data from various distributions to a normal distribution.

The power transform is useful as a transformation in modeling problems where homoscedasticity and normality are desired. Below are examples of Box-Cox and Yeo-Johnson applied to six different probability distributions: Lognormal, Chi-squared, Weibull, Gaussian, Uniform, and Bimodal.

Note that the transformations successfully map the data to a normal distribution when applied to certain datasets, but are ineffective with others. This highlights the importance of visualizing the data before and after transformation.

Also note that even though Box-Cox seems to perform better than Yeo-Johnson for lognormal and chi-squared distributions, keep in mind that Box-Cox does not support inputs with negative values.

For comparison, we also add the output from `QuantileTransformer`. It can force any arbitrary distribution into a gaussian, provided that there are enough training samples (thousands). Because it is a non-parametric method, it is harder to interpret than the parametric ones (Box-Cox and Yeo-Johnson).

On “small” datasets (less than a few hundred points), the quantile transformer is prone to overfitting. The use of the power transform is then recommended.

6.27.5 Feature discretization

A demonstration of feature discretization on synthetic classification datasets. Feature discretization decomposes each feature into a set of bins, here equally distributed in width. The discrete values are then one-hot encoded, and given to a linear classifier. This preprocessing enables a non-linear behavior even though the classifier is linear.

On this example, the first two rows represent linearly non-separable datasets (moons and concentric circles) while the third is approximately linearly separable. On the two linearly non-separable datasets, feature discretization largely increases the performance of linear classifiers. On the linearly separable dataset, feature discretization decreases the performance of linear classifiers. Two non-linear classifiers are also shown for comparison.

This example should be taken with a grain of salt, as the intuition conveyed does not necessarily carry over to real datasets. Particularly in high-dimensional spaces, data can more easily be separated linearly. Moreover, using feature discretization and one-hot encoding increases the number of features, which easily lead to overfitting when the number of samples is small.

The plots show training points in solid colors and testing points semi-transparent. The lower right shows the classification accuracy on the test set.

6.27.6 Compare the effect of different scalers on data with outliers

Feature 0 (median income in a block) and feature 5 (number of households) of the California Housing dataset have very different scales and contain some very large outliers. These two characteristics lead to difficulties to visualize the data and, more importantly, they can degrade the predictive performance of many machine learning algorithms. Unscaled data can also slow down or even prevent the convergence of many gradient-based estimators.

Indeed many estimators are designed with the assumption that each feature takes values close to zero or more importantly that all features vary on comparable scales. In particular, metric-based and gradient-based estimators often assume approximately standardized data (centered features with unit variances). A notable exception are decision tree-based estimators that are robust to arbitrary scaling of the data.

This example uses different scalers, transformers, and normalizers to bring the data within a pre-defined range.

Scalers are linear (or more precisely affine) transformers and differ from each other in the way they estimate the parameters used to shift and scale each feature.

QuantileTransformer provides non-linear transformations in which distances between marginal outliers and inliers are shrunk. PowerTransformer provides non-linear transformations in which data is mapped to a normal distribution to stabilize variance and minimize skewness.

Unlike the previous transformations, normalization refers to a per sample transformation instead of a per feature transformation.

The following code is a bit verbose, feel free to jump directly to the analysis of the results.

mpl.colorbar.ColorbarBase(ax_colorbar, cmap=cmap,
        norm=norm, orientation='vertical',
        label='Color mapping for values of y')
```

**Original data**

Each transformation is plotted showing two transformed features, with the left plot showing the entire dataset, and the right zoomed-in to show the dataset without the marginal outliers. A large majority of the samples are compacted to a specific range, [0, 10] for the median income and [0, 6] for the number of households. Note that there are some marginal outliers (some blocks have more than 1200 households). Therefore, a specific pre-processing can be very beneficial depending of the application. In the following, we present some insights and behaviors of those pre-processing methods in the presence of marginal outliers.

```
make_plot(0)
```
StandardScaler

StandardScaler removes the mean and scales the data to unit variance. The scaling shrinks the range of the feature values as shown in the left figure below. However, the outliers have an influence when computing the empirical mean and standard deviation. Note in particular that because the outliers on each feature have different magnitudes, the spread of the transformed data on each feature is very different: most of the data lie in the [-2, 4] range for the transformed median income feature while the same data is squeezed in the smaller [-0.2, 0.2] range for the transformed number of households.

StandardScaler therefore cannot guarantee balanced feature scales in the presence of outliers.

make_plot(1)
**MinMaxScaler**

`MinMaxScaler` rescales the data set such that all feature values are in the range [0, 1] as shown in the right panel below. However, this scaling compresses all inliers into the narrow range [0, 0.005] for the transformed number of households.

Both `StandardScaler` and `MinMaxScaler` are very sensitive to the presence of outliers.

```make_plot(2)```

**MaxAbsScaler**

`MaxAbsScaler` is similar to `MinMaxScaler` except that the values are mapped in the range [0, 1]. On positive only data, both scalers behave similarly. `MaxAbsScaler` therefore also suffers from the presence of large outliers.

```make_plot(3)```
RobustScaler

Unlike the previous scalers, the centering and scaling statistics of RobustScaler is based on percentiles and are therefore not influenced by a few number of very large marginal outliers. Consequently, the resulting range of the transformed feature values is larger than for the previous scalers and, more importantly, are approximately similar: for both features most of the transformed values lie in a [-2, 3] range as seen in the zoomed-in figure. Note that the outliers themselves are still present in the transformed data. If a separate outlier clipping is desirable, a non-linear transformation is required (see below).

make_plot(4)

PowerTransformer

PowerTransformer applies a power transformation to each feature to make the data more Gaussian-like in order to stabilize variance and minimize skewness. Currently the Yeo-Johnson and Box-Cox transforms are supported and the optimal scaling factor is determined via maximum likelihood estimation in both methods. By default, PowerTransformer applies zero-mean, unit variance normalization. Note that Box-Cox can only be applied to strictly positive data. Income and number of households happen to be strictly positive, but if negative values are present the Yeo-Johnson transformed is preferred.

make_plot(5)
make_plot(6)
QuantileTransformer (uniform output)

QuantileTransformer applies a non-linear transformation such that the probability density function of each feature will be mapped to a uniform or Gaussian distribution. In this case, all the data, including outliers, will be mapped to a uniform distribution with the range [0, 1], making outliers indistinguishable from inliers.

RobustScaler and QuantileTransformer are robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation. But contrary to RobustScaler, QuantileTransformer will also automatically collapse any outlier by setting them to the a priori defined range boundaries (0 and 1). This can result in saturation artifacts for extreme values.
QuantileTransformer (Gaussian output)

To map to a Gaussian distribution, set the parameter `output_distribution='normal'`.

```
make_plot(8)
```

![Data after quantile transformation (gaussian pdf)](image)

Normalizer

The Normalizer rescales the vector for each sample to have unit norm, independently of the distribution of the samples. It can be seen on both figures below where all samples are mapped onto the unit circle. In our example the two selected features have only positive values; therefore the transformed data only lie in the positive quadrant. This would not be the case if some original features had a mix of positive and negative values.

```
make_plot(9)
plt.show()
```

from sklearn.datasets import make_circles

# generate ring with inner box
n_samples = 200
X, y = make_circles(n_samples=n_samples, shuffle=False)
outer, inner = 0, 1
labels = np.full(n_samples, -1.)
labels[0] = outer
labels[-1] = inner

# Learn with LabelSpreading
label_spread = LabelSpreading(kernel='knn', alpha=0.8)
label_spread.fit(X, labels)

# Plot output labels
output_labels = label_spread.transduction_
plt.figure(figsize=(8.5, 4))
plt.subplot(1, 2, 1)
plt.scatter(X[labels == outer, 0], X[labels == outer, 1], color='navy', marker='s', lw=0, label="outer labeled", s=10)
```
6.28.3 Label Propagation digits: Demonstrating performance

This example demonstrates the power of semisupervised learning by training a Label Spreading model to classify handwritten digits with sets of very few labels.

The handwritten digit dataset has 1797 total points. The model will be trained using all points, but only 30 will be labeled. Results in the form of a confusion matrix and a series of metrics over each class will be very good.

At the end, the top 10 most uncertain predictions will be shown.
Learning with small amount of labeled data

```
Out:

Label Spreading model: 40 labeled & 300 unlabeled points (340 total)

6.28.4 Label Propagation digits active learning

Demonstrates an active learning technique to learn handwritten digits using label propagation.

We start by training a label propagation model with only 10 labeled points, then we select the top five most uncertain points to label. Next, we train with 15 labeled points (original 10 + 5 new ones). We repeat this process four times to have a model trained with 30 labeled examples. Note you can increase this to label more than 30 by changing max_iterations. Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique.

A plot will appear showing the top 5 most uncertain digits for each iteration of training. These may or may not contain mistakes, but we will train the next model with their true labels.

6.29 Support Vector Machines

Examples concerning the `sklearn.svm` module.

6.29.1 Non-linear SVM

Perform binary classification using non-linear SVC with RBF kernel. The target to predict is a XOR of the inputs. The color map illustrates the decision function learned by the SVC.

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

xx, yy = np.meshgrid(np.linspace(-3, 3, 500),
                     np.linspace(-3, 3, 500))
np.random.seed(0)
X = np.random.randn(300, 2)
Y = np.logical_xor(X[:, 0] > 0, X[:, 1] > 0)
```

```python
# fit the model
clf = svm.NuSVC(gamma='auto')
clf.fit(X, Y)

# plot the decision function for each datapoint on the grid
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
plt.imshow(Z, interpolation='nearest',
          extent=(xx.min(), xx.max(), yy.min(), yy.max()), aspect='auto',
          origin='lower', cmap=plt.cm.PuOr_r)
contours = plt.contour(xx, yy, Z, levels=[0], linewidths=2,
                      linestyles='dashed')
plt.scatter(X[:, 0], X[:, 1], s=30, c=Y, cmap=plt.cm.Paired,
            edgecolors='k')
plt.xticks(()
plt.yticks(()
plt.axis([-3, 3, -3, 3])
plt.show()
```

**Total running time of the script:** (0 minutes 3.374 seconds)

### 6.29.2 SVM: Maximum margin separating hyperplane

Plot the maximum margin separating hyperplane within a two-class separable dataset using a Support Vector Machine classifier with linear kernel.
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
from sklearn.datasets import make_blobs

# we create 40 separable points
X, y = make_blobs(n_samples=40, centers=2, random_state=6)

# fit the model, don't regularize for illustration purposes
clf = svm.SVC(kernel='linear', C=1000)
clf.fit(X, y)

plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)

# plot the decision function
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)

(continues on next page)
YY, XX = np.meshgrid(yy, xx)
xy = np.vstack([XX.ravel(), YY.ravel()]).T
Z = clf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins
ax.contour(XX, YY, Z, colors='k', levels=[-1, 0, 1], alpha=0.5,
           linestyles=['--', '-', '--'])

# plot support vectors
ax.scatter(clf.support_vectors_[:, 0], clf.support_vectors_[:, 1], s=100,
           linewidth=1, facecolors='none', edgecolors='k')
plt.show()

Total running time of the script: (0 minutes 0.075 seconds)

6.29.3 SVM with custom kernel

Simple usage of Support Vector Machines to classify a sample. It will plot the decision surface and the support vectors.

3-Class classification using Support Vector Machine with custom kernel

Out:
/home/circleci/project/examples/svm/plot_custom_kernel.py:50:
  - MatplotlibDeprecationWarning: shading='flat' when X and Y have the same dimensions
  - as C is deprecated since 3.3. Either specify the corners of the quadrilaterals
  - with X and Y, or pass shading='auto', 'nearest' or 'gouraud', or set rcParams
  - {'color.shading'}. This will become an error two minor releases later.
plt.pcolormesh(xx, yy, Z, cmap=plt.cm.Paired)

Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])

# Put the result into a color plot
Z = Z.reshape(xx.shape)
plt.pcolormesh(xx, yy, Z, cmap=plt.cm.Paired)

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=Y, cmap=plt.cm.Paired, edgecolors='k')
plt.title('3-Class classification using Support Vector Machine with custom' + ' kernel')
plt.axis('tight')
plt.show()
6.29.4 SVM Tie Breaking Example

Tie breaking is costly if `decision_function_shape='ovr'`, and therefore it is not enabled by default. This example illustrates the effect of the `break_ties` parameter for a multiclass classification problem and `decision_function_shape='ovr'`.

The two plots differ only in the area in the middle where the classes are tied. If `break_ties=False`, all input in that area would be classified as one class, whereas if `break_ties=True`, the tie-breaking mechanism will create a non-convex decision boundary in that area.
print(__doc__)

    ax.set_aspect("equal")

plt.show()
6.29.5 SVM: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.

The sample weighting rescales the C parameter, which means that the classifier puts more emphasis on getting these points right. The effect might often be subtle. To emphasize the effect here, we particularly weight outliers, making the deformation of the decision boundary very visible.

```python
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

def plot_decision_function(classifier, sample_weight, axis, title):
    # plot the decision function
    xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))
    Z = classifier.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)

    # plot the line, the points, and the nearest vectors to the plane
    axis.contourf(xx, yy, Z, alpha=0.75, cmap=plt.cm.bone)
    axis.scatter(X[:, 0], X[:, 1], c=y, s=100 * sample_weight, alpha=0.9,
                 cmap=plt.cm.bone, edgecolors='black')

    axis.axis('off')
    axis.set_title(title)

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]
y = [1] * 10 + [-1] * 10
sample_weight_last_ten = abs(np.random.randn(len(X)))
sample_weight_constant = np.ones(len(X))

# and bigger weights to some outliers
sample_weight_last_ten[15:] *= 5
```

(continues on next page)
sample_weight_last_ten[9] *= 15

# for reference, first fit without sample weights

# fit the model
clf_weights = svm.SVC(gamma=1)
clf_weights.fit(X, y, sample_weight=sample_weight_last_ten)

clf_no_weights = svm.SVC(gamma=1)
clf_no_weights.fit(X, y)

fig, axes = plt.subplots(1, 2, figsize=(14, 6))
plot_decision_function(clf_no_weights, sample_weight_constant, axes[0],
                      "Constant weights")
plot_decision_function(clf_weights, sample_weight_last_ten, axes[1],
                      "Modified weights")
plt.show()

Total running time of the script: 0 minutes 0.910 seconds

6.29.6 Plot the support vectors in LinearSVC

Unlike SVC (based on LIBSVM), LinearSVC (based on LIBLINEAR) does not provide the support vectors. This example demonstrates how to obtain the support vectors in LinearSVC.

import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_blobs
from sklearn.svm import LinearSVC

X, y = make_blobs(n_samples=40, centers=2, random_state=0)
plt.figure(figsize=(10, 5))
for i, C in enumerate([1, 100]):
    # "hinge" is the standard SVM loss
    clf = LinearSVC(C=C, loss="hinge", random_state=42).fit(X, y)
    # obtain the support vectors through the decision function
    decision_function = clf.decision_function(X)
    # we can also calculate the decision function manually
    # decision_function = np.dot(X, clf.coef_[0]) + clf.intercept_[0]
    # The support vectors are the samples that lie within the margin
    # boundaries, whose size is conventionally constrained to 1
    support_vector_indices = np.where(np.abs(decision_function) <= 1 + 1e-15)[0]
    support_vectors = X[support_vector_indices]
    plt.subplot(1, 2, i + 1)
    plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)
    ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()
xx, yy = np.meshgrid(np.linspace(xlim[0], xlim[1], 50),
                     np.linspace(ylim[0], ylim[1], 50))
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
plt.contour(xx, yy, Z, colors='k', levels=[-1, 0, 1], alpha=0.5,
            linestyles=['--', '-', '--'])
plt.scatter(support_vectors[:, 0], support_vectors[:, 1], s=100,
            linewidth=1, facecolors='none', edgecolors='k')
plt.title("C="+ str(C))
plt.tight_layout()
plt.show()

Total running time of the script: ( 0 minutes 0.152 seconds)

6.29.7 SVM: Separating hyperplane for unbalanced classes

Find the optimal separating hyperplane using an SVC for classes that are unbalanced.

We first find the separating plane with a plain SVC and then plot (dashed) the separating hyperplane with automatically correction for unbalanced classes.

Note: This example will also work by replacing `SVC(kernel="linear")` with `SGDClassifier(loss="hinge")`. Setting the `loss` parameter of the `SGDClassifier` equal to `hinge` will yield behaviour such as that of a SVC with a linear kernel.

For example try instead of the SVC:

```
clf = SGDClassifier(n_iter=100, alpha=0.01)
```
```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
from sklearn.datasets import make_blobs

# we create two clusters of random points
n_samples_1 = 1000
n_samples_2 = 100
centers = [[0.0, 0.0], [2.0, 2.0]]
clusters_std = [1.5, 0.5]
X, y = make_blobs(n_samples=[n_samples_1, n_samples_2],
                  centers=centers,
                  cluster_std=clusters_std,
                  random_state=0, shuffle=False)

# fit the model and get the separating hyperplane
clf = svm.SVC(kernel='linear', C=1.0)
clf.fit(X, y)

# fit the model and get the separating hyperplane using weighted classes
wclf = svm.SVC(kernel='linear', class_weight={1: 10})
wclf.fit(X, y)
```

(figures and diagrams continued on the next page)
# plot the samples
plt.scatter(X[:, 0], X[:, 1], c=y, cmap=plt.cm.Paired, edgecolors='k')

# plot the decision functions for both classifiers
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)
YY, XX = np.meshgrid(yy, xx)
xy = np.vstack((XX.ravel(), YY.ravel())).T

# get the separating hyperplane
Z = clf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins
a = ax.contour(XX, YY, Z, colors='k', levels=[0], alpha=0.5, linestyles=['-'])

# get the separating hyperplane for weighted classes
Z = wclf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins for weighted classes
b = ax.contour(XX, YY, Z, colors='r', levels=[0], alpha=0.5, linestyles=['-'])

plt.legend([a.collections[0], b.collections[0]], ['non weighted', 'weighted'], loc='upper right')
plt.show()

Total running time of the script: ( 0 minutes 0.134 seconds)

### 6.29.8 SVM-Kernels

Three different types of SVM-Kernels are displayed below. The polynomial and RBF are especially useful when the data-points are not linearly separable.
print(__doc__)
# Our dataset and targets

```python
X = np.c_[(.4, -.7),
    (-1.5, -1),
    (-1.4, -.9),
    (-1.3, -1.2),
    (-1.1, -.2),
    (-1.2, -.4),
    (-.5, 1.2),
    (-1.5, 2.1),
    (1, 1),
    (1.3, .8),
    (1.2, .5),
    (.2, -2),
    (.5, -2.4),
    (.2, -2.3),
    (0, -2.7),
    (1.3, 2.1)].T
Y = [0] * 8 + [1] * 8
```

# figure number

```
fignum = 1
```

# fit the model

```
for kernel in ('linear', 'poly', 'rbf'):
    clf = svm.SVC(kernel=kernel, gamma=2)
    clf.fit(X, Y)

    # plot the line, the points, and the nearest vectors to the plane
    plt.figure(fignum, figsize=(4, 3))
    plt.clf()
    plt.scatter(clf.support_vectors_[:, 0], clf.support_vectors_[:, 1], s=80,
                facecolors='none', zorder=10, edgecolors='k')
    plt.scatter(X[:, 0], X[:, 1], c=Y, zorder=10, cmap=plt.cm.Paired,
                edgecolors='k')
    plt.axis('tight')
    x_min = -3
    x_max = 3
    y_min = -3
    y_max = 3

    XX, YY = np.mgrid[x_min:x_max:200j, y_min:y_max:200j]
    Z = clf.decision_function(np.c_[XX.ravel(), YY.ravel()])

    # Put the result into a color plot
    Z = Z.reshape(XX.shape)
    plt.figure(fignum, figsize=(4, 3))
    plt.pcolormesh(XX, YY, Z > 0, cmap=plt.cm.Paired)
    plt.contour(XX, YY, Z, colors=['k', 'k', 'k'], linestyles=['--', '-', '--'],
                levels=[-.5, 0, .5])
    plt.xlim(x_min, x_max)
    plt.ylim(y_min, y_max)
    plt.xticks(()
```

(continues on next page)
6.29.9 SVM-Anova: SVM with univariate feature selection

This example shows how to perform univariate feature selection before running a SVC (support vector classifier) to improve the classification scores. We use the iris dataset (4 features) and add 36 non-informative features. We can find that our model achieves best performance when we select around 10% of features.
# Import some data to play with
X, y = load_iris(return_X_y=True)

# Add non-informative features
np.random.seed(0)
X = np.hstack((X, 2 * np.random.random((X.shape[0], 36))))

# Create a feature-selection transform, a scaler and an instance of SVM that we
# combine together to have a full-blown estimator
clf = Pipeline([('anova', SelectPercentile(chi2)),
                 ('scaler', StandardScaler()),
                 ('svc', SVC(gamma="auto"))])

# Plot the cross-validation score as a function of percentile of features
score_means = list()
score_stds = list()
percentiles = (1, 3, 6, 10, 15, 20, 30, 40, 60, 80, 100)

for percentile in percentiles:
    clf.set_params(anova__percentile=percentile)
    this_scores = cross_val_score(clf, X, y)
    score_means.append(this_scores.mean())
    score_stds.append(this_scores.std())

plt.errorbar(percentiles, score_means, np.array(score_stds))
plt.title('Performance of the SVM-Anova varying the percentile of features selected')
plt.xticks(np.linspace(0, 100, 11, endpoint=True))
plt.xlabel('Percentile')
plt.ylabel('Accuracy Score')
plt.axis('tight')
plt.show()

6.29.11 SVM Margins Example

The plots below illustrate the effect the parameter \( C \) has on the separation line. A large value of \( C \) basically tells our model that we do not have that much faith in our data’s distribution, and will only consider points close to line of separation.

A small value of \( C \) includes more/all the observations, allowing the margins to be calculated using all the data in the area.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

# we create 40 separable points
np.random.seed(0)
X = np.r_[np.random.randn(20, 2) - [2, 2], np.random.randn(20, 2) + [2, 2]]
Y = [0] * 20 + [1] * 20

plt.pcolormesh(XX, YY, Z, cmap=plt.cm.Paired)
plt.contourf(XX, YY, Z, alpha=0.75)
plt.ylabel('y')
plt.axis('tight')
plt.show()
fignum = 1

# fit the model
for name, penalty in [('unreg', 1), ('reg', 0.05)]:
    clf = svm.SVC(kernel='linear', C=penalty)
    clf.fit(X, Y)

    # get the separating hyperplane
    w = clf.coef_[0]
    a = -w[0] / w[1]
    xx = np.linspace(-5, 5)
    yy = a * xx - (clf.intercept_[0]) / w[1]

    # plot the parallels to the separating hyperplane that pass through the
    # support vectors (margin away from hyperplane in direction
    # perpendicular to hyperplane). This is sqrt(1+a^2) away vertically in
    # 2-d.
    margin = 1 / np.sqrt(np.sum(clf.coef_ ** 2))
    yy_down = yy - np.sqrt(1 + a ** 2) * margin
    yy_up = yy + np.sqrt(1 + a ** 2) * margin

    # plot the line, the points, and the nearest vectors to the plane
    plt.figure(fignum, figsize=(4, 3))
    plt.clf()
    plt.plot(xx, yy, 'k-')
    plt.plot(xx, yy_down, 'k--')
    plt.plot(xx, yy_up, 'k--')
    plt.scatter(clf.support_vectors_[:, 0], clf.support_vectors_[:, 1], s=80,
                facecolors='none', zorder=10, edgecolors='k')

### 6.29.13 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width

This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models `LinearSVC()` and `SVC(kernel='linear')` yield slightly different decision boundaries. This can be a consequence of the following differences:

- `LinearSVC` minimizes the squared hinge loss while `SVC` minimizes the regular hinge loss.
- LinearSVC uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while SVC uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

**Note:** while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don’t always generalize to more realistic high-dimensional problems.

```python
print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm, datasets

def make_meshgrid(x, y, h=.02):
    """Create a mesh of points to plot in

    Parameters
    ----------
    x: data to base x-axis meshgrid on
    y: data to base y-axis meshgrid on
    h: stepsize for meshgrid (optional, default=0.02)
    """
```
y: data to base y-axis meshgrid on  
h: stepsize for meshgrid, optional

Returns  
-------  
xx, yy : ndarray

```python
x_min, x_max = x.min() - 1, x.max() + 1
y_min, y_max = y.min() - 1, y.max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h),
                     np.arange(y_min, y_max, h))
return xx, yy
```

```python
def plot_contours(ax, clf, xx, yy, **params):
    """Plot the decision boundaries for a classifier.

    Parameters
    ----------
    ax: matplotlib axes object
    clf: a classifier

6.29.14 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using Support Vector Machines for classification. For SVC classification, we are interested in a risk minimization for the equation:

\[ C \sum_{i=1}^{n} \mathcal{L}(f(x_i), y_i) + \Omega(w) \]

where

- \( C \) is used to set the amount of regularization
- \( \mathcal{L} \) is a loss function of our samples and our model parameters.
- \( \Omega \) is a penalty function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, cross validation, to set the amount of regularization with \( C \), there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.

Since our loss function is dependent on the amount of samples, the latter will influence the selected value of \( C \). The question that arises is How do we optimally adjust \( C \) to account for the different amount of training samples?

The figures below are used to illustrate the effect of scaling our \( C \) to compensate for the change in the number of samples, in the case of using an l1 penalty, as well as the l2 penalty.

l1-penalty case

In the l1 case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the l1. It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling C1.
I2-penalty case

The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

Simulations

The two figures below plot the values of $C$ on the $x$-axis and the corresponding cross-validation scores on the $y$-axis, for several different fractions of a generated data-set.

In the $l_1$ penalty case, the cross-validation-error correlates best with the test-error, when scaling our $C$ with the number of samples, $n$, which can be seen in the first figure.

For the $l_2$ penalty case, the best result comes from the case where $C$ is not scaled.

Note:

Two separate datasets are used for the two different plots. The reason behind this is the $l_1$ case works better on sparse data, while $l_2$ is better suited to the non-sparse case.

6.29.15 RBF SVM parameters

This example illustrates the effect of the parameters $\gamma$ and $C$ of the Radial Basis Function (RBF) kernel SVM. Intuitively, the $\gamma$ parameter defines how far the influence of a single training example reaches, with low values meaning ‘far’ and high values meaning ‘close’. The $\gamma$ parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

The $C$ parameter trades off correct classification of training examples against maximization of the decision function’s margin. For larger values of $C$, a smaller margin will be accepted if the decision function is better at classifying all training points correctly. A lower $C$ will encourage a larger margin, therefore a simpler decision function, at the cost of training accuracy. In other words $C$ behaves as a regularization parameter in the SVM.

The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier’s cross-validation accuracy as a function of $C$ and $\gamma$. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from $10^{-3}$ to $10^{3}$ is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye.

The behavior of the model is very sensitive to the $\gamma$ parameter. If $\gamma$ is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with $C$ will be able to prevent overfitting.

When $\gamma$ is very small, the model is too constrained and cannot capture the complexity or “shape” of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

For intermediate values, we can see on the second plot that good models can be found on a diagonal of $C$ and $\gamma$. Smooth models (lower $\gamma$ values) can be made more complex by increasing the importance of classifying each point correctly (larger $C$ values) hence the diagonal of good performing models.

Finally, one can also observe that for some intermediate values of $\gamma$ we get equally performing models when $C$ becomes very large. This suggests that the set of support vectors does not change anymore. The radius of the RBF kernel alone acts as a good structural regularizer. Incrementing $C$ further doesn’t help, likely because there are no more training points in violation (inside the margin or wrongly classified), or at least no better solution can be found. Scores being equal, it may make sense to use the smaller $C$ values, since very high $C$ values typically increase fitting time.

On the other hand, lower $C$ values generally lead to more support vectors, which may increase prediction time. Therefore, lowering the value of $C$ involves a trade-off between fitting time and prediction time.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations $n_{\text{splits}}$ at the expense of compute time. Increasing the value number of $C_{\text{range}}$ and $\gamma_{\text{range}}$ steps will increase the resolution of the hyper-parameter heat map.
The best parameters are {'C': 1.0, 'gamma': 0.1} with a score of 0.97

6.31.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- TfidfVectorizer uses an in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.

- HashingVectorizer hashes word occurrences to a fixed dimensional space, possibly with collisions. The word count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

HashingVectorizer does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a TfidfTransformer instance.
Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the “ground truth” provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called “Concentration of Measure” or “Curse of Dimensionality” for high dimensional datasets such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

Out:

Usage: plot_document_clustering.py [options]

Options:
- -h, --help show this help message and exit
- --lsa=N_COMPONENTS Preprocess documents with latent semantic analysis.
- --no-minibatch Use ordinary k-means algorithm (in batch mode).
- --no-idf Disable Inverse Document Frequency feature weighting.
- --use-hashing Use a hashing feature vectorizer
- --n-features=N_FEATURES Maximum number of features (dimensions) to extract from text.
- --verbose Print progress reports inside k-means algorithm.

LinearSVC with L1-based feature selection

Training:
Pipeline(steps=[('feature_selection',
    SelectFromModel(estimator=LinearSVC(dual=False, penalty='l1'),
    n_features_to_select=10000)],
    prefit=True)
Add plots

The bar plot indicates the accuracy, training time (normalized) and test time (normalized) of each classifier.

```python
indices = np.arange(len(results))
results = [[x[i] for x in results] for i in range(4)]
clf_names, score, training_time, test_time = results
training_time = np.array(training_time) / np.max(training_time)
test_time = np.array(test_time) / np.max(test_time)

plt.figure(figsize=(12, 8))
plt.title("Score")
plt.barh(indices, score, .2, label="score", color='navy')
plt.barh(indices + .3, training_time, .2, label="training time", color='c')
plt.barh(indices + .6, test_time, .2, label="test time", color='darkorange')
plt.yticks(()
plt.legend(loc='best')
plt.subplots_adjust(left=.25)
plt.subplots_adjust(top=.95)
plt.subplots_adjust(bottom=.05)

for i, c in zip(indices, clf_names):
    plt.text(-.3, i, c)

plt.show()
```
Total running time of the script: (0 minutes 4.237 seconds)
This is the class and function reference of scikit-learn. Please refer to the full user guide for further details, as the class and function raw specifications may not be enough to give full guidelines on their uses. For reference on concepts repeated across the API, see Glossary of Common Terms and API Elements.

7.1 sklearn.base: Base classes and utility functions

Base classes for all estimators.

7.1.1 Base classes

<table>

**sklearn.base.BaseEstimator**

class sklearn.base.BaseEstimator

Base class for all estimators in scikit-learn.
Notes

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

Methods

```
get_params([deep]) Get parameters for this estimator.

set_params(**params) Set the parameters of this estimator.
```

`get_params (deep=True)`

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

`set_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- `**params` [dict] Estimator parameters.

**Returns**

Examples using `sklearn.base.BaseEstimator`

- Approximate nearest neighbors in TSNE

`sklearn.base.BiclusterMixin`

**class sklearn.base.BiclusterMixin**

Mixin class for all bicluster estimators in scikit-learn.

**Attributes**

- `biclusters_` Convenient way to get row and column indicators together.
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_indices(i)</td>
<td>Row and column indices of the $i$'th bicluster.</td>
</tr>
<tr>
<td>get_shape(i)</td>
<td>Shape of the $i$'th bicluster.</td>
</tr>
<tr>
<td>get_submatrix(i, data)</td>
<td>Return the submatrix corresponding to bicluster $i$.</td>
</tr>
</tbody>
</table>

**property biclusters_

Convenient way to get row and column indicators together.

Returns the rows_ and columns_ members.

**get_indices (i)

Row and column indices of the $i$'th bicluster.

Only works if rows_ and columns_ attributes exist.

Parameters

- i [int] The index of the cluster.

Returns

- row_ind [ndarray, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
- col_ind [ndarray, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

**get_shape (i)

Shape of the $i$'th bicluster.

Parameters

- i [int] The index of the cluster.

Returns

- n_rows [int] Number of rows in the bicluster.
- n_cols [int] Number of columns in the bicluster.

**get_submatrix (i, data)

Return the submatrix corresponding to bicluster $i$.

Parameters

- i [int] The index of the cluster.
- data [array-like of shape (n_samples, n_features)] The data.

Returns

- submatrix [ndarray of shape (n_rows, n_cols)] The submatrix corresponding to bicluster $i$. 
Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

sklearn.base.ClassifierMixin

class sklearn.base.ClassifierMixin
    Mixin class for all classifiers in scikit-learn.

    Methods

    score(X, y[, sample_weight])
        Return the mean accuracy on the given test data and labels.

        score(X, y, sample_weight=None)
        Return the mean accuracy on the given test data and labels.
        In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

        Parameters
        X [array-like of shape (n_samples, n_features)] Test samples.
        y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
        sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

        Returns
        score [float] Mean accuracy of self.predict(X) wrt. y.

sklearn.base.ClusterMixin

class sklearn.base.ClusterMixin
    Mixin class for all cluster estimators in scikit-learn.

    Methods

    fit_predict(X[, y])
        Perform clustering on X and returns cluster labels.

    fit_predict(X, y=None)
        Perform clustering on X and returns cluster labels.

        Parameters
        X [array-like of shape (n_samples, n_features)] Input data.
        y [Ignored] Not used, present for API consistency by convention.

        Returns
        labels [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.
sklearn.base.DensityMixin

class sklearn.base.DensityMixin
    Mixin class for all density estimators in scikit-learn.

    Methods

    score(X[, y])
        Return the score of the model on the data X.

        Parameters
        X [array-like of shape (n_samples, n_features)] Test samples.
        y [None] Not used, present for API consistency by convention.

        Returns
        score [float]

sklearn.base.RegressorMixin

class sklearn.base.RegressorMixin
    Mixin class for all regression estimators in scikit-learn.

    Methods

    score(X, y[, sample_weight])
        Return the coefficient of determination $R^2$ of the prediction.

        Parameters
        X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
        y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
        sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

        Returns
        score [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`sklearn.base.TransformerMixin`

class `sklearn.base.TransformerMixin`

    Mixin class for all transformers in scikit-learn.

    **Methods**

    __init__

    Fit to data, then transform it.

    `fit_transform(X[, y])`

    Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

    Parameters

    `X` [array-like of shape (n_samples, n_features)] Input samples.

    `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

    `**fit_params` [dict] Additional fit parameters.

    Returns

    `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

Examples using `sklearn.base.TransformerMixin`

- Approximate nearest neighbors in TSNE

`sklearn.feature_selection.SelectorMixin`

class `sklearn.feature_selection.SelectorMixin`

    Transformer mixin that performs feature selection given a support mask

    This mixin provides a feature selector implementation with `transform` and `inverse_transform` functionality given an implementation of `_get_support_mask`.
Methods

**fit_transform**(X[, y]) Fit to data, then transform it.
**get_support**(indices) Get a mask, or integer index, of the features selected
**inverse_transform**(X) Reverse the transformation operation
**transform**(X) Reduce X to the selected features.

**fit_transform**(X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_support**(indices=False)
Get a mask, or integer index, of the features selected

Parameters

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

- **support** [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(X)
Reverse the transformation operation

Parameters

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

Returns

- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**transform**(X)
Reduce X to the selected features.

Parameters

- **X** [array of shape [n_samples, n_features]] The input samples.

Returns
X_r  [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.1.2 Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>base.clone</strong> (estimator, <em>[, safe])</em>*</td>
<td>Constructs a new estimator with the same parameters.</td>
</tr>
<tr>
<td><strong>base.is_classifier</strong> (estimator)</td>
<td>Return True if the given estimator is (probably) a classifier.</td>
</tr>
<tr>
<td><strong>base.is_regressor</strong> (estimator)</td>
<td>Return True if the given estimator is (probably) a regressor.</td>
</tr>
<tr>
<td><strong>config_context</strong> (**new_config)</td>
<td>Context manager for global scikit-learn configuration</td>
</tr>
<tr>
<td><strong>get_config</strong> ()</td>
<td>Retrieve current values for configuration set by <strong>set_config</strong></td>
</tr>
<tr>
<td><strong>set_config</strong> ([assume_finite, working_memory,...])</td>
<td>Set global scikit-learn configuration</td>
</tr>
<tr>
<td><strong>show_versions</strong> ()</td>
<td>Print useful debugging information”</td>
</tr>
</tbody>
</table>

**sklearn.base.clone**

**sklearn.base.clone** (estimator, *, safe=True)

Constructs a new estimator with the same parameters.

Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fit on any data.

Parameters

- **estimator** [{list, tuple, set} of estimator instance or a single estimator instance] The estimator or group of estimators to be cloned.
- **safe** [bool, default=True] If safe is False, clone will fall back to a deep copy on objects that are not estimators.

**sklearn.base.is_classifier**

**sklearn.base.is_classifier** (estimator)

Return True if the given estimator is (probably) a classifier.

Parameters

- **estimator** [object] Estimator object to test.

Returns

- **out** [bool] True if estimator is a classifier and False otherwise.
sklearn.base.is_regressor

sklearn.base.is_regressor(estimator)
Return True if the given estimator is (probably) a regressor.

Parameters

estimator [estimator instance] Estimator object to test.

Returns

out [bool] True if estimator is a regressor and False otherwise.

sklearn.config_context

sklearn.config_context(**new_config)
Context manager for global scikit-learn configuration

Parameters

assume_finite [bool, default=False] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

working_memory [int, default=1024] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

print_changed_only [bool, default=True] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, print(SVC()) while True will only print ‘SVC()’, but would print ‘SVC(C=1.0, cache_size=200, . . .)’ with all the non-changed parameters when False. Default is True.

Changed in version 0.23: Default changed from False to True.

display [{'text', 'diagram'}, default='text'] If ‘diagram’, estimators will be displayed as a diagram in a Jupyter lab or notebook context. If ‘text’, estimators will be displayed as text. Default is ‘text’.

New in version 0.23.

See also:

set_config Set global scikit-learn configuration.
get_config Retrieve current values of the global configuration.

Notes

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.
Examples

```python
>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...     assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...     with sklearn.config_context(assume_finite=False):
...         assert_all_finite([float('nan')])
Traceback (most recent call last):
  ... ValueError: Input contains NaN, ...
```

**sklearn.get_config**

`sklearn.get_config()`

Retrieve current values for configuration set by `set_config`

**Returns**

- `config` [dict] Keys are parameter names that can be passed to `set_config`.

**See also:**

- `config_context` Context manager for global scikit-learn configuration.
- `set_config` Set global scikit-learn configuration.

**sklearn.set_config**

`sklearn.set_config(assume_finite=None, working_memory=None, print_changed_only=None, display=None)`

Set global scikit-learn configuration

New in version 0.19.

**Parameters**

- `assume_finite` [bool, default=None] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

  New in version 0.19.

- `working_memory` [int, default=None] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

  New in version 0.20.

- `print_changed_only` [bool, default=None] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print ‘SVC()’ while the default behaviour would be to print ‘SVC(C=1.0, cache_size=200, . . .)’ with all the non-changed parameters.

  New in version 0.21.
display  [‘text’, ‘diagram’], default=None] If ‘diagram’, estimators will be displayed as a diagram in a Jupyter lab or notebook context. If ‘text’, estimators will be displayed as text. Default is ‘text’.

New in version 0.23.

See also:

config_context  Context manager for global scikit-learn configuration.

get_config  Retrieve current values of the global configuration.

Examples using sklearn.set_config

• Release Highlights for scikit-learn 0.23
• Compact estimator representations
• Column Transformer with Mixed Types

sklearn.show_versions

sklearn.showVersions()

Print useful debugging information”

New in version 0.20.

7.2 sklearn.calibration: Probability Calibration

Calibration of predicted probabilities.

User guide: See the Probability calibration section for further details.

calibration.CalibratedClassifierCV(**kwargs)  Probability calibration with isotonic regression or logistic regression.

7.2.1 sklearn.calibration.CalibratedClassifierCV

class sklearn.calibration.CalibratedClassifierCV(**kwargs)

Probability calibration with isotonic regression or logistic regression.

This class uses cross-validation to both estimate the parameters of a classifier and subsequently calibrate a classifier. For each cv split it fits a copy of the base estimator to the training folds, and calibrates it using the testing fold. For prediction, predicted probabilities are averaged across these individual calibrated classifiers.

Already fitted classifiers can be calibrated via the parameter cv=”prefit”. In this case, no cross-validation is used and all provided data is used for calibration. The user has to take care manually that data for model fitting and calibration are disjoint.

The calibration is based on the decision_function method of the base_estimator if it exists, else on predict_proba.

Read more in the User Guide.

Parameters
**base_estimator** [estimator instance, default=None] The classifier whose output need to be calibrated to provide more accurate predict_proba outputs. The default classifier is a LinearSVC.

**method** [{'sigmoid', 'isotonic'}, default='sigmoid'] The method to use for calibration. Can be 'sigmoid' which corresponds to Platt's method (i.e. a logistic regression model) or 'isotonic' which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples (<1000) since it tends to overfit.

**cv** [int, cross-validation generator, iterable or “prefit”, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds,
- `CV splitter`,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if y is binary or multiclass, StratifiedKFold is used. If y is neither binary nor multiclass, KFold is used.

Refer to the User Guide for the various cross-validation strategies that can be used here.

If “prefit” is passed, it is assumed that `base_estimator` has been fitted already and all data is used for calibration.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors.

Base estimator clones are fitted in parallel across cross-validation iterations. Therefore parallelism happens only when cv != “prefit”.

See Glossary for more details.

New in version 0.24.

**Attributes**

classes_ [ndarray of shape (n_classes,)] The class labels.

calibrated_classifiers_ [list (len() equal to cv or 1 if cv == “prefit”)] The list of calibrated classifiers, one for each cross-validation split, which has been fitted on training folds and calibrated on the testing fold.

</tr>
</tbody>
</table>

```python
fit(X, y, sample_weight=None)
```

**Parameters**

7.2. sklearn.calibration: Probability Calibration
X [array-like of shape (n_samples, n_features)] Training data.
y [array-like of shape (n_samples,)] Target values.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict the target of new samples. The predicted class is the class that has the highest probability, and can thus be different from the prediction of the uncalibrated classifier.

Parameters

X [array-like of shape (n_samples, n_features)] The samples.

Returns

C [ndarray of shape (n_samples,)] The predicted class.

predict_proba (X)
Posterior probabilities of classification
This function returns posterior probabilities of classification according to each class on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)] The samples.

Returns

C [ndarray of shape (n_samples, n_classes)] The predicted probas.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.calibration.CalibratedClassifierCV`

- *Probability Calibration curves*
- *Probability calibration of classifiers*
- *Probability Calibration for 3-class classification*

```python
calibration.calibration_curve(y_true, y_prob, *)
```

Compute true and predicted probabilities for a calibration curve.

7.2.2 `sklearn.calibration.calibration_curve`

`sklearn.calibration.calibration_curve` *(y_true, y_prob, *, normalize=False, n_bins=5, strategy='uniform')*

Compute true and predicted probabilities for a calibration curve.

The method assumes the inputs come from a binary classifier, and discretize the [0, 1] interval into bins. Calibration curves may also be referred to as reliability diagrams.

Read more in the *User Guide*.

Parameters

- **y_true** [array-like of shape (n_samples,)] True targets.
- **y_prob** [array-like of shape (n_samples,)] Probabilities of the positive class.
- **normalize** [bool, default=False] Whether y_prob needs to be normalized into the [0, 1] interval, i.e. is not a proper probability. If True, the smallest value in y_prob is linearly mapped onto 0 and the largest one onto 1.
- **n_bins** [int, default=5] Number of bins to discretize the [0, 1] interval. A bigger number requires more data. Bins with no samples (i.e. without corresponding values in y_prob) will not be returned, thus the returned arrays may have less than n_bins values.
- **strategy** [['uniform', 'quantile'], default='uniform'] Strategy used to define the widths of the bins.
  - **uniform** The bins have identical widths.
  - **quantile** The bins have the same number of samples and depend on y_prob.

Returns
prob_true  [ndarray of shape (n_bins,) or smaller] The proportion of samples whose class is the positive class, in each bin (fraction of positives).

prob_pred  [ndarray of shape (n_bins,) or smaller] The mean predicted probability in each bin.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.calibration import calibration_curve
>>> y_true = np.array([0, 0, 0, 0, 1, 1, 1, 1, 1])
>>> y_pred = np.array([0.1, 0.2, 0.3, 0.4, 0.65, 0.7, 0.8, 0.9, 1.])
>>> prob_true, prob_pred = calibration_curve(y_true, y_pred, n_bins=3)
>>> prob_true
array([0. , 0.5, 1. ])
>>> prob_pred
array([0.2 , 0.525, 0.85 ])
```

**sklearn.cluster.AffinityPropagation**

class `sklearn.cluster.AffinityPropagation(**kwargs)`

Perform Affinity Propagation Clustering of data.

Read more in the *User Guide*.

Parameters

- **damping** [float, default=0.5] Damping factor (between 0.5 and 1) is the extent to which the current value is maintained relative to incoming values (weighted 1 - damping). This in order to avoid numerical oscillations when updating these values (messages).
- **max_iter** [int, default=200] Maximum number of iterations.
- **convergence_iter** [int, default=15] Number of iterations with no change in the number of estimated clusters that stops the convergence.
- **copy** [bool, default=True] Make a copy of input data.
- **preference** [array-like of shape (n_samples,) or float, default=None] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.
- **affinity** [‘euclidean’, ‘precomputed’], default=’euclidean’) Which affinity to use. At the moment ‘precomputed’ and euclidean are supported. ‘euclidean’ uses the negative squared euclidean distance between points.
- **verbose** [bool, default=False] Whether to be verbose.
- **random_state** [int, RandomState instance or None, default=0] Pseudo-random number generator to control the starting state. Use an int for reproducible results across function calls. See the *Glossary*.

New in version 0.23: this parameter was previously hardcoded as 0.

Attributes

- **cluster_centers_indices_** [ndarray of shape (n_clusters,)] Indices of cluster centers.
- **cluster_centers_** [ndarray of shape (n_clusters, n_features)] Cluster centers (if affinity != precomputed).
- **labels_** [ndarray of shape (n_samples,)] Labels of each point.
- **affinity_matrix_** [ndarray of shape (n_samples, n_samples)] Stores the affinity matrix used in fit.
- **n_iter_** [int] Number of iterations taken to converge.
Notes

For an example, see examples/cluster/plot_affinity_propagation.py.

The algorithmic complexity of affinity propagation is quadratic in the number of points.

When fit does not converge, cluster_centers_ becomes an empty array and all training samples will be labelled as -1. In addition, predict will then label every sample as -1.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, fit will result in a single cluster center and label 0 for every sample. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

References

Examples

```python
>>> from sklearn.cluster import AffinityPropagation
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0], ...
... [4, 2], [4, 4], [4, 0]])
>>> clustering = AffinityPropagation(random_state=5).fit(X)
>>> clustering
AffinityPropagation(random_state=5)
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
>>> clustering.predict([[0, 0], [4, 4]])
array([0, 1])
>>> clustering.cluster_centers_
array([[1, 2],
        [4, 2]])
```

Methods

- **fit**(X[, y])
  Fit the clustering from features, or affinity matrix.
- **fit_predict**(X[, y])
  Fit the clustering from features or affinity matrix, and return cluster labels.
- **get_params**(deep)
  Get parameters for this estimator.
- **predict**(X)
  Predict the closest cluster each sample in X belongs to.
- **set_params**(**params)
  Set the parameters of this estimator.

**fit**(X, y=None)
Fit the clustering from features, or affinity matrix.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse feature matrix is provided, it will
be converted into a sparse `csr_matrix`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self

**fit_predict** *(X, y=None)*

Fit the clustering from features or affinity matrix, and return cluster labels.

Parameters

**X** [[array-like, sparse matrix] of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse feature matrix is provided, it will be converted into a sparse `csr_matrix`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray of shape (n_samples,)] Cluster labels.

g**et_params** *(deep=True)*

Get parameters for this estimator.

Parameters

d**eep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict the closest cluster each sample in X belongs to.

Parameters

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to predict. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns

labels [ndarray of shape (n_samples,)] Cluster labels.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.cluster.AffinityPropagation`

- Demo of affinity propagation clustering algorithm
- Comparing different clustering algorithms on toy datasets

`sklearn.cluster.AgglomerativeClustering`

```python
class sklearn.cluster.AgglomerativeClustering(**kwargs)
```

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Read more in the User Guide.

Parameters

- `n_clusters` [int or None, default=2] The number of clusters to find. It must be None if distance_threshold is not None.
- `affinity` [str or callable, default='euclidean'] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or “precomputed”. If linkage is “ward”, only “euclidean” is accepted. If “precomputed”, a distance matrix (instead of a similarity matrix) is needed as input for the fit method.
- `memory` [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.
- `connectivity` [array-like or callable, default=None] Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.
- `compute_full_tree` [‘auto’ or bool, default=‘auto’] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be True if distance_threshold is not None. By default compute_full_tree is “auto”, which is equivalent to True when distance_threshold is not None or that n_clusters is inferior to the maximum between 100 or 0.02 * n_samples. Otherwise, “auto” is equivalent to False.
- `linkage` [‘ward’, ‘complete’, ‘average’, ‘single’], default=’ward’] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of cluster that minimize this criterion.
  - ‘ward’ minimizes the variance of the clusters being merged.
  - ‘average’ uses the average of the distances of each observation of the two sets.
  - ‘complete’ or ‘maximum’ linkage uses the maximum distances between all observations of the two sets.
  - ‘single’ uses the minimum of the distances between all observations of the two sets.

New in version 0.20: Added the ‘single’ option
**distance_threshold** [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not None, n_clusters must be None and compute_full_tree must be True.

New in version 0.21.

**compute_distances** [bool, default=False] Computes distances between clusters even if distance_threshold is not used. This can be used to make dendrogram visualization, but introduces a computational and memory overhead.

New in version 0.24.

**Attributes**

- **n_clusters_** [int] The number of clusters found by the algorithm. If distance_threshold=None, it will be equal to the given n_clusters.
- **labels_** [ndarray of shape (n_samples)] cluster labels for each point
- **n_leaves_** [int] Number of leaves in the hierarchical tree.
- **n_connected_components_** [int] The estimated number of connected components in the graph.
  
  New in version 0.21: n_connected_components_ was added to replace n_components_.
- **children_** [array-like of shape (n_samples-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children[i-1 - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i
- **distances_** [array-like of shape (n_nodes-1,)] Distances between nodes in the corresponding place in children_. Only computed if distance_threshold is used or compute_distances is set to True.

**Examples**

```python
>>> from sklearn.cluster import AgglomerativeClustering
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0], ... [4, 2], [4, 4], [4, 0]])
>>> clustering = AgglomerativeClustering().fit(X)
>>> clustering
AgglomerativeClustering()
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
```

**Methods**

- **fit(X[, y])** Fit the hierarchical clustering from features, or distance matrix.
- **fit_predict(X[, y])** Fit the hierarchical clustering from features or distance matrix, and return cluster labels.
- **get_params([deep])** Get parameters for this estimator.
- **set_params(**params)** Set the parameters of this estimator.
**fit** (*X*, *y=None*)

Fit the hierarchical clustering from features, or distance matrix.

**Parameters**

*X* [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if *affinity='precomputed'*.  

*y* [Ignored] Not used, present here for API consistency by convention.

**Returns**

*self*

**fit_predict** (*X*, *y=None*)

Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

**Parameters**

*X* [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if *affinity='precomputed'*.  

*y* [Ignored] Not used, present here for API consistency by convention.

**Returns**

*labels* [ndarray of shape (n_samples,)] Cluster labels.

**get_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [dict] Parameter names mapped to their values.

**set_params** (**params**)  

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

*self* [estimator instance] Estimator instance.
Examples using `sklearn.cluster.AgglomerativeClustering`

- Plot Hierarchical Clustering Dendrogram
- Agglomerative clustering with and without structure
- Various Agglomerative Clustering on a 2D embedding of digits
- A demo of structured Ward hierarchical clustering on an image of coins
- Hierarchical clustering: structured vs unstructured ward
- Agglomerative clustering with different metrics

- Comparing different clustering algorithms on toy datasets

### sklearn.cluster.Birch

**class sklearn.cluster.Birch(**kwargs)**

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to `MiniBatchKMeans`. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as `AgglomerativeClustering`.

Read more in the User Guide.

New in version 0.16.

#### Parameters

- `threshold` [float, default=0.5] The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.

- `branching_factor` [int, default=50] Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the branching_factor then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

- `n_clusters` [int, instance of sklearn.cluster model, default=3] Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.
  - None: the final clustering step is not performed and the subclusters are returned as they are.
  - `sklearn.cluster` Estimator: If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest subcluster.
  - int: the model fit is `AgglomerativeClustering` with `n_clusters` set to be equal to the int.

- `compute_labels` [bool, default=True] Whether or not to compute labels for each fit.

- `copy` [bool, default=True] Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

#### Attributes
root_  [_CFNode] Root of the CFTree.
dummy_leaf_  [_CFNode] Start pointer to all the leaves.
subcluster_centers_  [ndarray] Centroids of all subclusters read directly from the leaves.
subcluster_labels_  [ndarray] Labels assigned to the centroids of the subclusters after they are clustered globally.
labels_  [ndarray of shape (n_samples,)] Array of labels assigned to the input data. if partial_fit is used instead of fit, they are assigned to the last batch of data.

See also:

MiniBatchKMeans  Alternative implementation that does incremental updates of the centers’ positions using mini-batches.

Notes

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

**fit (X, y=None)**
Build a CF Tree for the input data.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Input data.
- **y** (Ignored) Not used, present here for API consistency by convention.

**Returns**

- **self** Fitted estimator.

**fit_predict (X, y=None)**
Perform clustering on X and returns cluster labels.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input data.
- **y** (Ignored) Not used, present for API consistency by convention.

**Returns**

- **labels** [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.

**fit_transform (X, y=None, **fit_params)**
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params (deep=True)**
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params  [dict] Parameter names mapped to their values.

partial_fit (X=None, y=None)
Online learning. Prevents rebuilding of CFTree from scratch.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features), default=None] Input data.
    If X is not provided, only the global clustering step is done.

y  [Ignored] Not used, present here for API consistency by convention.

Returns

self  Fitted estimator.

predict (X)
Predict data using the centroids_ of subclusters.
Avoid computation of the row norms of X.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Input data.

Returns

labels  [ndarray of shape(n_samples,)] Labelled data.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

transform (X)
Transform X into subcluster centroids dimension.
Each dimension represents the distance from the sample point to each cluster centroid.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Input data.

Returns

X_trans  [{array-like, sparse matrix} of shape (n_samples, n_clusters)] Transformed data.
Examples using `sklearn.cluster.Birch`

- Compare BIRCH and MiniBatchKMeans
- Comparing different clustering algorithms on toy datasets

### `sklearn.cluster.DBSCAN`

**class `sklearn.cluster.DBSCAN(**kwargs)**

Perform DBSCAN clustering from vector array or distance matrix.

DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.

Read more in the User Guide.

**Parameters**

- `eps` [float, default=0.5] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

- `min_samples` [int, default=5] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

- `metric` [string, or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its metric parameter. If metric is "precomputed", X is assumed to be a distance matrix and must be square. X may be a Glossary, in which case only “nonzero” elements may be considered neighbors for DBSCAN.

New in version 0.17: metric `precomputed` to accept precomputed sparse matrix.

- `metric_params` [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.19.

- `algorithm` [´auto´, ´ball_tree´, ´kd_tree´, ´brute´], default=´auto´] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

- `leaf_size` [int, default=30] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- `p` [float, default=None] The power of the Minkowski metric to be used to calculate distance between points. If None, then p=2 (equivalent to the Euclidean distance).

- `n_jobs` [int, default=None] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**Attributes**

- `core_sample_indices_` [ndarray of shape (n_core_samples,)] Indices of core samples.

- `components_` [ndarray of shape (n_core_samples, n_features)] Copy of each core sample found by training.
labels_ [ndarray of shape (n_samples)] Cluster labels for each point in the dataset given to fit().
    Noisy samples are given the label -1.

See also:

OPTICS A similar clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see examples/cluster/plot_dbscan.py.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n).

It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using NearestNeighbors.radius_neighbors_graph with mode='distance', then using metric='precomputed' here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use sample_weight instead.

cluster.OPTICS provides a similar clustering with lower memory usage.

**fit** *(X, y=None, sample_weight=None)*

Perform DBSCAN clustering from features, or distance matrix.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if metric='precomputed'. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

- **sample_weight** [array-like of shape (n_samples,), default=None] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

- **y** [Ignored] Not used, present here for API consistency by convention.

Returns

- **self**

**fit_predict** *(X, y=None, sample_weight=None)*

Perform DBSCAN clustering from features or distance matrix, and return cluster labels.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if metric='precomputed'. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

- **sample_weight** [array-like of shape (n_samples,), default=None] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

- **y** [Ignored] Not used, present here for API consistency by convention.

Returns

- **labels** [ndarray of shape (n_samples,)] Cluster labels. Noisy samples are given the label -1.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using sklearn.cluster.DBSCAN**

- Demo of DBSCAN clustering algorithm
- Comparing different clustering algorithms on toy datasets

**sklearn.cluster.FeatureAgglomeration**

**class** sklearn.cluster.FeatureAgglomeration(**kwargs**)  
Agglomerate features.

Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the User Guide.

**Parameters**

**n_clusters** [int, default=2] The number of clusters to find. It must be None if `distance_threshold` is not None.

**affinity** [str or callable, default='euclidean'] Metric used to compute the linkage. Can be "euclidean", "l1", "l2", "manhattan", "cosine", or ‘precomputed’. If linkage is “ward”, only “euclidean” is accepted.

**memory** [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

**connectivity** [array-like or callable, default=None] Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

**compute_full_tree** ['auto' or bool, default='auto'] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be True if `distance_threshold` is not None. By default `compute_full_tree` is “auto”, which is equivalent to True when `distance_threshold` is not None or that `n_clusters` is inferior to the maximum between 100 or 0.02 * n_samples. Otherwise, “auto” is equivalent to False.
linkage  [{‘ward’, ‘complete’, ‘average’, ‘single’}, default=’ward’] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of features. The algorithm will merge the pairs of cluster that minimize this criterion.

- ward minimizes the variance of the clusters being merged.
- average uses the average of the distances of each feature of the two sets.
- complete or maximum linkage uses the maximum distances between all features of the two sets.
- single uses the minimum of the distances between all observations of the two sets.

pooling_func  [callable, default=np.mean] This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument axis=1, and reduce it to an array of size [M].

distance_threshold  [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not None, n_clusters must be None and compute_full_tree must be True.

New in version 0.21.

compute_distances  [bool, default=False] Computes distances between clusters even if distance_threshold is not used. This can be used to make dendrogram visualization, but introduces a computational and memory overhead.

New in version 0.24.

Attributes

n_clusters_  [int] The number of clusters found by the algorithm. If distance_threshold=None, it will be equal to the given n_clusters.

labels_  [array-like of (n_features,)] cluster labels for each feature.

n_leaves_  [int] Number of leaves in the hierarchical tree.

n_connected_components_  [int] The estimated number of connected components in the graph.

New in version 0.21: n_connected_components_ was added to replace n_components_.

children_  [array-like of shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_features correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_features is a non-leaf node and has children children_[i - n_features], Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_features + i

distances_  [array-like of shape (n_nodes-1,)] Distances between nodes in the corresponding place in children_. Only computed if distance_threshold is used or compute_distances is set to True.
Examples

```python
>>> import numpy as np
>>> from sklearn import datasets, cluster
digits = datasets.load_digits()
images = digits.images
X = np.reshape(images, (len(images), -1))
agglo = cluster.FeatureAgglomeration(n_clusters=32)
agglo.fit(X)
X_reduced = agglo.transform(X)
X_reduced.shape
(1797, 32)
```

Methods

- `fit(X[, y])`: Fit the hierarchical clustering on the data
- `fit_transform(X[, y])`: Fit to data, then transform it.
- `get_params([deep])`: Get parameters for this estimator.
- `inverse_transform(Xred)`: Inverse the transformation.
- `set_params(**params)`: Set the parameters of this estimator.
- `transform(X)`: Transform a new matrix using the built clustering

```python
fit(X, y=None, **params)
Fit the hierarchical clustering on the data

Parameters

X [array-like of shape (n_samples, n_features)] The data
y [Ignored]

Returns

self

property fit_predict
Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

Parameters

X [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if affinity='precomputed'.
y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray of shape (n_samples,)]] Cluster labels.

fit_transform(X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (Xred)
Inverse the transformation. Return a vector of size nb_features with the values of Xred assigned to each group of features

Parameters

Xred [array-like of shape (n_samples, n_clusters) or (n_clusters,)] The values to be assigned to each cluster of samples

Returns

X [ndarray of shape (n_samples, n_features) or (n_features,)] A vector of size n_samples with the values of Xred assigned to each of the cluster of samples.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Transform a new matrix using the built clustering

Parameters

X [array-like of shape (n_samples, n_features) or (n_samples,)] A M by N array of M observations in N dimensions or a length M array of M one-dimensional observations.

Returns

Y [ndarray of shape (n_samples, n_clusters) or (n_clusters,)] The pooled values for each feature cluster.
Examples using `sklearn.cluster.FeatureAgglomeration`

- Feature agglomeration
- Feature agglomeration vs. univariate selection

### sklearn.cluster.KMeans

```python
class sklearn.cluster.KMeans(**kwargs)
```

K-Means clustering.

Read more in the User Guide.

**Parameters**

- **n_clusters** [int, default=8] The number of clusters to form as well as the number of centroids to generate.
- **init** [{'k-means++', 'random'}, callable or array-like of shape (n_clusters, n_features), default='k-means++'] Method for initialization:
  - 'k-means++': selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in `k_init` for more details.
  - 'random': choose `n_clusters` observations (rows) at random from data for the initial centers.
  - If an array is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
  - If a callable is passed, it should take arguments X, n_clusters and a random state and return an initialization.
- **n_init** [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- **max_iter** [int, default=300] Maximum number of iterations of the k-means algorithm for a single run.
- **tol** [float, default=1e-4] Relative tolerance with regards to Frobenius norm of the difference in the cluster centers of two consecutive iterations to declare convergence.
- **precompute_distances** [{'auto', True, False}, default='auto'] Precompute distances (faster but takes more memory).
  - 'auto': do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
  - True: always precompute distances.
  - False: never precompute distances.
  - Deprecated since version 0.23: `precompute_distances` was deprecated in version 0.22 and will be removed in 0.25. It has no effect.
- **verbose** [int, default=0] Verbosity mode.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See Glossary.
**copy_x** [bool, default=True] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True (default), then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean. Note that if the original data is not C-contiguous, a copy will be made even if copy_x is False. If the original data is sparse, but not in CSR format, a copy will be made even if copy_x is False.

**n_jobs** [int, default=None] The number of OpenMP threads to use for the computation. Parallelism is sample-wise on the main cython loop which assigns each sample to its closest center.

None or -1 means using all processors.

Deprecated since version 0.23: n_jobs was deprecated in version 0.23 and will be removed in 0.25.

**algorithm** [{“auto”, “full”, “elkan”}, default=“auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient on data with well-defined clusters, by using the triangle inequality. However it’s more memory intensive due to the allocation of an extra array of shape (n_samples, n_clusters).

For now “auto” (kept for backward compatibiliy) chooses “elkan” but it might change in the future for a better heuristic.

Changed in version 0.18: Added Elkan algorithm

**Attributes**

**cluster_centers_** [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers. If the algorithm stops before fully converging (see tol and max_iter), these will not be consistent with labels_.

**labels_** [ndarray of shape (n_samples,)] Labels of each point

**inertia_** [float] Sum of squared distances of samples to their closest cluster center.

**n_iter_** [int] Number of iterations run.

See also:

**MiniBatchKMeans** Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say n_samples > 10k) MiniBatchKMeans is probably much faster than the default batch implementation.

**Notes**

The k-means problem is solved using either Lloyd’s or Elkan’s algorithm.

The average complexity is given by O(k n T), were n is the number of samples and T is the number of iteration. The worst case complexity is given by O(n^(k+2/p)) with n = n_samples, p = n_features. (D. Arthur and S. Vassilvitski, ‘How slow is the k-means method?’ SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That’s why it can be useful to restart it several times.

If the algorithm stops before fully converging (because of tol or max_iter), labels_ and cluster_centers_ will not be consistent, i.e. the cluster_centers_ will not be the means of the points in each cluster. Also, the estimator will reassign labels_ after the last iteration to make labels_ consistent with predict on the training set.
Examples

```python
>>> from sklearn.cluster import KMeans
>>> import numpy as np

X = np.array([[1, 2], [1, 4], [1, 0],
              [10, 2], [10, 4], [10, 0]])

kmeans = KMeans(n_clusters=2, random_state=0).fit(X)

kmeans.labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)

kmeans.predict([[0, 0], [12, 3]])
array([1, 0], dtype=int32)

kmeans.cluster_centers_
array([[10., 2.],
       [ 1., 2.]])
```

**fit (X, y=None, sample_weight=None)**

Compute k-means clustering.

**Parameters**

- X ([array-like, sparse matrix] of shape (n_samples, n_features)) Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous. If a sparse matrix is passed, a copy will be made if it’s not in CSR format.
- y [Ignored] Not used, present here for API consistency by convention.
- sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

New in version 0.20.

**Returns**

- self Fitted estimator.

**fit_predict (X, y=None, sample_weight=None)**

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

**Parameters**

- X...
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.
y  [Ignored] Not used, present here for API consistency by convention.
sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns
labels  [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

fit_transform (X, y=None, sample_weight=None)  
Compute clustering and transform X to cluster-distance space.
Equivalent to fit(X).transform(X), but more efficiently implemented.

Parameters
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.
y  [Ignored] Not used, present here for API consistency by convention.
sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns
X_new  [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.

get_params (deep=True)  
Get parameters for this estimator.

Parameters
deeep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params  [dict] Parameter names mapped to their values.

predict (X, sample_weight=None)  
Predict the closest cluster each sample in X belongs to.
In the vector quantization literature, cluster_centers_ is called the code book and each value returned by predict is the index of the closest code in the code book.

Parameters
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.
sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns
labels  [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

score (X, y=None, sample_weight=None)  
Opposite of the value of X on the K-means objective.

Parameters
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] New data.
y  [Ignored] Not used, present here for API consistency by convention.
sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns
score [float] Opposite of the value of X on the K-means objective.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform (X)
Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by transform will typically be dense.

Parameters
X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

Returns
X_new [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.

Examples using sklearn.cluster.KMeans

- Release Highlights for scikit-learn 0.23
- Demonstration of k-means assumptions
- Vector Quantization Example
- K-means Clustering
- Color Quantization using K-Means
- Empirical evaluation of the impact of k-means initialization

- A demo of K-Means clustering on the handwritten digits data
- Selecting the number of clusters with silhouette analysis on KMeans clustering
- Clustering text documents using k-means
**sklearn.cluster.MiniBatchKMeans**

class sklearn.cluster.MiniBatchKMeans(**kwargs)

Mini-Batch K-Means clustering.

Read more in the User Guide.

Parameters

- **n_clusters** [int, default=8] The number of clusters to form as well as the number of centroids to generate.
- **init** [‘k-means++’, ‘random’], callable or array-like of shape (n_clusters, n_features), default=’k-means++’ Method for initialization:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose n_clusters observations (rows) at random from data for the initial centers.
  - If an array is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
  - If a callable is passed, it should take arguments X, n_clusters and a random state and return an initialization.
- **max_iter** [int, default=100] Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.
- **batch_size** [int, default=100] Size of the mini batches.
- **verbose** [int, default=0] Verbosity mode.
- **compute_labels** [bool, default=True] Compute label assignment and inertia for the complete dataset once the minibatch optimization has converged in fit.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for centroid initialization and random reassignment. Use an int to make the randomness deterministic. See Glossary.
- **tol** [float, default=0.0] Control early stopping based on the relative center changes as measured by a smoothed, variance-normalized of the mean center squared position changes. This early stopping heuristics is closer to the one used for the batch variant of the algorithms but induces a slight computational and memory overhead over the inertia heuristic.
  - To disable convergence detection based on normalized center change, set tol to 0.0 (default).
- **max_no_improvement** [int, default=10] Control early stopping based on the consecutive number of mini batches that does not yield an improvement on the smoothed inertia.
  - To disable convergence detection based on inertia, set max_no_improvement to None.
- **init_size** [int, default=None] Number of samples to randomly sample for speeding up the initialization (sometimes at the expense of accuracy): the only algorithm is initialized by running a batch KMeans on a random subset of the data. This needs to be larger than n_clusters.
  - If None, init_size= 3 * batch_size.
- **n_init** [int, default=3] Number of random initializations that are tried. In contrast to KMeans, the algorithm is only run once, using the best of the n_init initializations as measured by inertia.
reassignment_ratio [float, default=0.01] Control the fraction of the maximum number of
counts for a center to be reassigned. A higher value means that low count centers are more
easily reassigned, which means that the model will take longer to converge, but should con-
verge in a better clustering.

Attributes

cluster_centers_ [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers.
labels_ [int] Labels of each point (if compute_labels is set to True).
inertia_ [float] The value of the inertia criterion associated with the chosen partition (if com-
pute_labels is set to True). The inertia is defined as the sum of square distances of samples
to their nearest neighbor.
n_iter_ [int] Number of batches processed.
counts_ [ndarray of shape (n_clusters,)] Weigth sum of each cluster.

Deprecation since version 0.24: This attribute is deprecated in 0.24 and will be removed in
0.26.
init_size_ [int] The effective number of samples used for the initialization.

Deprecation since version 0.24: This attribute is deprecated in 0.24 and will be removed in
0.26.

**fit** (X, y=None, sample_weight=None)

Compute the centroids on X by chunking it into mini-batches.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.
- **y** [Ignored] Not used, present here for API consistency by convention.
- **sample_weight** [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

New in version 0.20.

**Returns**

self

**fit_predict** (X, y=None, sample_weight=None)

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) New data to transform.
- **y** [Ignored] Not used, present here for API consistency by convention.
- **sample_weight** [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.
Returns

labels [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

fit_transform (X, y=None, sample_weight=None)
Compute clustering and transform X to cluster-distance space.
Equivalent to fit(X).transform(X), but more efficiently implemented.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.
y [Ignored] Not used, present here for API consistency by convention.
sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns

X_new [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.

generate (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

partial_fit (X, y=None, sample_weight=None)
Update k means estimate on a single mini-batch X.

Parameters

X [array-like of shape (n_samples, n_features)] Coordinates of the data points to cluster. It must be noted that X will be copied if it is not C-contiguous.
y [Ignored] Not used, present here for API consistency by convention.
sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

self

predict (X, sample_weight=None)
Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, cluster_centers_ is called the code book and each value returned by predict is the index of the closest code in the code book.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to predict.
sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.
score \((X, y=None, sample_weight=None)\)
Opposite of the value of X on the K-means objective.

**Parameters**

- X \([\text{array-like, sparse matrix}] \text{ of shape (n\_samples, n\_features)}\) New data.
- y [Ignored] Not used, present here for API consistency by convention.
- sample_weight \([\text{array-like of shape (n\_samples,)}, \text{ default=None}]\) The weights for each observation in X. If None, all observations are assigned equal weight.

**Returns**

- score [float] Opposite of the value of X on the K-means objective.

set_params (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params [dict] Estimator parameters.**

**Returns**

transform \((X)\)
Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by transform will typically be dense.

**Parameters**

- X \([\text{array-like, sparse matrix}] \text{ of shape (n\_samples, n\_features)}\) New data to transform.

**Returns**

- X\_new [ndarray of shape (n\_samples, n\_clusters)] X transformed in the new space.

**Examples using sklearn.cluster.MiniBatchKMeans**

- Biclustering documents with the Spectral Co-clustering algorithm
- Online learning of a dictionary of parts of faces
- Compare BIRCH and MiniBatchKMeans
- Empirical evaluation of the impact of k-means initialization
- Comparison of the K-Means and MiniBatchKMeans clustering algorithms
- Comparing different clustering algorithms on toy datasets
- Faces dataset decompositions
- Clustering text documents using k-means

7.3. sklearn.cluster: Clustering
scikit-learn user guide, Release 0.24.dev0

sklearn.cluster.MeanShift

class sklearn.cluster.MeanShift(**kwargs)

Mean shift clustering using a flat kernel.

Mean shift clustering aims to discover “blobs” in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the User Guide.

Parameters

- **bandwidth** [float, default=None] Bandwidth used in the RBF kernel.
  
  If not given, the bandwidth is estimated using sklearn.cluster.estimate_bandwidth; see the documentation for that function for hints on scalability (see also the Notes, below).

- **seeds** [array-like of shape (n_samples, n_features), default=None] Seeds used to initialize kernels. If not set, the seeds are calculated by clustering.get_bin_seeds with bandwidth as the grid size and default values for other parameters.

- **bin_seeding** [bool, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. The default value is False. Ignored if seeds argument is not None.

- **min_bin_freq** [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

- **cluster_all** [bool, default=True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

- **n_jobs** [int, default=None] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.
  
  None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

- **max_iter** [int, default=300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

  New in version 0.22.

Attributes

- **cluster_centers_** [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers.

- **labels_** [ndarray of shape (n_samples,)] Labels of each point.

- **n_iter_** [int] Maximum number of iterations performed on each seed.

  New in version 0.22.
Notes

Scalability:

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards $O(T \times n \times \log(n))$ in lower dimensions, with $n$ the number of samples and $T$ the number of points. In higher dimensions the complexity will tend towards $O(T \times n^2)$.

Scalability can be boosted by using fewer seeds, for example by using a higher value of min_bin_freq in the get_bin_seeds function.

Note that the estimate_bandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

References

Examples

```python
>>> from sklearn.cluster import MeanShift
>>> import numpy as np

>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])

>>> clustering = MeanShift(bandwidth=2).fit(X)

>>> clustering.labels_
aarray([1, 1, 1, 0, 0, 0])

>>> clustering.predict([[0, 0], [5, 5]])
aarray([1, 0])

>>> clustering
MeanShift(bandwidth=2)
```

**fit** *(X, y=None)*

Perform clustering.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Samples to cluster.
- **y** [Ignored]

**fit_predict** *(X, y=None)*

Perform clustering on X and returns cluster labels.

Parameters
X [array-like of shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

labels [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.

get_params (deep=True)

Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)

Predict the closest cluster each sample in X belongs to.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.

Returns

labels [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

- Comparing different clustering algorithms on toy datasets

sklearn.cluster.OPTICS

class sklearn.cluster.OPTICS(**kwargs)

Estimate clustering structure from vector array.

OPTICS (Ordering Points To Identify the Clustering Structure), closely related to DBSCAN, finds core sample of high density and expands clusters from them [1]. Unlike DBSCAN, keeps cluster hierarchy for a variable neighborhood radius. Better suited for usage on large datasets than the current sklearn implementation of DBSCAN.
Clusters are then extracted using a DBSCAN-like method (\texttt{cluster\_method = 'dbscan'}) or an automatic technique proposed in [1] (\texttt{cluster\_method = 'xi')}).

This implementation deviates from the original OPTICS by first performing k-nearest-neighborhood searches on all points to identify core sizes, then computing only the distances to unprocessed points when constructing the cluster order. Note that we do not employ a heap to manage the expansion candidates, so the time complexity will be \(O(n^2)\).

Read more in the \textit{User Guide}.

\textbf{Parameters}

\begin{itemize}
  \item \textbf{min\_samples} [int > 1 or float between 0 and 1, default=5] The number of samples in a neighborhood for a point to be considered as a core point. Also, up and down steep regions can't have more than \texttt{min\_samples} consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).
  \item \textbf{max\_eps} [float, default=np.inf] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of \texttt{np.inf} will identify clusters across all scales; reducing \texttt{max\_eps} will result in shorter run times.
  \item \textbf{metric} [str or callable, default='minkowski'] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.
  \begin{itemize}
    \item If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string. If metric is “precomputed”, \(X\) is assumed to be a distance matrix and must be square.
  \end{itemize}
  \begin{itemize}
    \item Valid values for \texttt{metric} are:
    \begin{itemize}
      \item from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
      \item from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']
    \end{itemize}
  \end{itemize}
  \begin{itemize}
    \item See the documentation for scipy.spatial.distance for details on these metrics.
  \end{itemize}
  \item \textbf{p} [int, default=2] Parameter for the Minkowski metric from \texttt{pairwise\_distances}. When \(p = 1\), this is equivalent to using \texttt{manhattan\_distance (l1)} and \texttt{euclidean\_distance (l2)} for \(p = 2\). For arbitrary \(p\), \texttt{minkowski\_distance (l\_p)} is used.
  \item \textbf{metric\_params} [dict, default=None] Additional keyword arguments for the metric function.
  \item \textbf{cluster\_method} [str, default='xi'] The extraction method used to extract clusters using the calculated reachability and ordering. Possible values are “xi” and “dbscan”.
  \item \textbf{eps} [float, default=None] The maximum distance between two samples for one to be considered as in the neighborhood of the other. By default it assumes the same value as \texttt{max\_eps}. Used only when \texttt{cluster\_method = 'dbscan'}.\(\)
  \item \textbf{xi} [float between 0 and 1, default=0.05] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi. Used only when \texttt{cluster\_method = 'xi'}.\(\)
  \item \textbf{predecessor\_correction} [bool, default=True] Correct clusters according to the predecessors calculated by OPTICS [2]. This parameter has minimal effect on most datasets. Used only when \texttt{cluster\_method = 'xi'}.\(\)
\end{itemize}
**min_cluster_size** [int > 1 or float between 0 and 1, default=None] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If None, the value of min_samples is used instead. Used only when cluster_method='xi'.

**algorithm** [['auto', 'ball_tree', 'kd_tree', 'brute'], default='auto'] Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use BallTree
- 'kd_tree' will use KDTree
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to fit method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

**labels_** [ndarray of shape (n_samples,)] Cluster labels for each point in the dataset given to fit(). Noisy samples and points which are not included in a leaf cluster of cluster_hierarchy_ are labeled as -1.

**reachability_** [ndarray of shape (n_samples,)] Reachability distances per sample, indexed by object order. Use clust.reachability_[clust.ordering_] to access in cluster order.

**ordering_** [ndarray of shape (n_samples,)] The cluster ordered list of sample indices.

**core_distances_** [ndarray of shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use clust.core_distances_[clust.ordering_] to access in cluster order.

**predecessor_** [ndarray of shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

**cluster_hierarchy_** [ndarray of shape (n_clusters, 2)] The list of clusters in the form of [start, end] in each row, with all indices inclusive. The clusters are ordered according to (end, -start) (ascending) so that larger clusters encompassing smaller clusters come after those smaller ones. Since labels_ does not reflect the hierarchy, usually len(cluster_hierarchy_) > np.unique(optics.labels_). Please also note that these indices are of the ordering_, i.e. X[ordering_][start:end + 1] form a cluster. Only available when cluster_method='xi'.

See also:

**DBSCAN** A similar clustering for a specified neighborhood radius (eps). Our implementation is optimized for runtime.

**fit**(X, y=None)
Perform OPTICS clustering.

Extracts an ordered list of points and reachability distances, and performs initial clustering using `max_eps` distance specified at OPTICS object instantiation.

**Parameters**

- **X**
  - [ndarray of shape (n_samples, n_features), or (n_samples, n_samples) if metric=’precomputed’] A feature array, or array of distances between samples if metric=’precomputed’.
- **y**
  - [Ignored] Ignored.

**Returns**

- **self**
  - [instance of OPTICS] The instance.

**fit_predict**(X, y=None)
Perform clustering on X and returns cluster labels.

**Parameters**

- **X**
  - [array-like of shape (n_samples, n_features)] Input data.
- **y**
  - [Ignored] Not used, present for API consistency by convention.

**Returns**

- **labels**
  - [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep**
  - [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.cluster.OPTICS

• Demo of OPTICS clustering algorithm
• Comparing different clustering algorithms on toy datasets

sklearn.cluster.SpectralClustering

class sklearn.cluster.SpectralClustering(**kwargs)
Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling fit, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distance $d(X, X)$:

```python
np.exp(-gamma * d(X, X) ** 2)
```

or a k-nearest neighbors connectivity matrix.

Alternatively, using precomputed, a user-provided affinity matrix can be used.

Read more in the User Guide.

Parameters

n_clusters [int, default=8] The dimension of the projection subspace.

eigen_solver [{‘arpack’, ‘lobpcg’, ‘amg’}, default=None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities. If None, then ‘arpack’ is used.

n_components [int, default=n_clusters] Number of eigen vectors to use for the spectral embedding

random_state [int, RandomState instance, default=None] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver='amg' and by the K-Means initialization. Use an int to make the randomness deterministic. See Glossary.
n_init [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

gamma [float, default=1.0] Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for affinity='nearest_neighbors'.

affinity [str or callable, default='rbf']

**How to construct the affinity matrix.**

- ‘nearest_neighbors’ : construct the affinity matrix by computing a graph of nearest neighbors.
- ‘rbf’ : construct the affinity matrix using a radial basis function (RBF) kernel.
- ‘precomputed’ : interpret X as a precomputed affinity matrix.
- ‘precomputed_nearest_neighbors’ : interpret X as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the n_neighbors nearest neighbors.
- one of the kernels supported by pairwise_kernels.

Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.

n_neighbors [int] Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for affinity='rbf'.

eigen_tol [float, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when eigen_solver='arpack'.

assign_labels [[‘kmeans’, ‘discretize’], default=’kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

degree [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

coeff0 [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params [dict of str to any, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

n_jobs [int, default=None] The number of parallel jobs to run when affinity='nearest_neighbors' or affinity='precomputed_nearest_neighbors'. The neighbors search will be done in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [bool, default=False] Verbosity mode.

New in version 0.24.

Attributes

- affinity_matrix_ [array-like of shape (n_samples, n_samples)] Affinity matrix used for clustering. Available only if after calling fit.
- labels_ [ndarray of shape (n_samples,)] Labels of each point
Notes

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values means very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

\[
\text{np.exp}\left(- \frac{\text{dist_matrix} \times 2}{(2. \times \text{delta} \times 2)}\right)
\]

Where \text{delta} is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points. If the pyamg package is installed, it is used: this greatly speeds up computation.

Examples

```python
>>> from sklearn.cluster import SpectralClustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralClustering(n_clusters=2, ...
... assign_labels="discretize", ...
... random_state=0).fit(X)
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
>>> clustering
SpectralClustering(assign_labels='discretize', n_clusters=2, random_state=0)
```

Methods

- `fit(X, y)` Perform spectral clustering from features, or affinity matrix.
- `fit_predict(X, y)` Perform spectral clustering from features, or affinity matrix, and return cluster labels.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.

```python
fit(X, y=None)  # Perform spectral clustering from features, or affinity matrix.
```

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse matrix is provided in a format other than csr_matrix, csc_matrix, or coo_matrix, it will be converted into a sparse csr_matrix.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self

fit_predict (X, y=None)
Perform spectral clustering from features, or affinity matrix, and return cluster labels.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse matrix is provided in a format other than csr_matrix, csc_matrix, or coo_matrix, it will be converted into a sparse csr_matrix.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray of shape (n_samples,)] Cluster labels.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.cluster.SpectralClustering`

- Comparing different clustering algorithms on toy datasets

`sklearn.cluster.SpectralBiclustering`

class `sklearn.cluster.SpectralBiclustering(**kwargs)`

Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure.

Read more in the `User Guide`.

Parameters

- **n_clusters** [int or tuple (n_row_clusters, n_column_clusters), default=3] The number of row and column clusters in the checkerboard structure.

- **method** [{'bistochastic', 'scale', 'log'}, default='bistochastic'] Method of normalizing and converting singular vectors into biclusters. May be one of 'scale', 'bistochastic', or 'log'. The authors recommend using 'log'. If the data is sparse, however, log normalization will not work, which is why the default is 'bistochastic'.

  Warning: if method='log', the data must be sparse.

- **n_components** [int, default=6] Number of singular vectors to check.

- **n_best** [int, default=3] Number of best singular vectors to which to project the data for clustering.

- **svd_method** [{'randomized', 'arpack'}, default='randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', uses `randomized_svd`, which may be faster for large matrices. If 'arpack', uses `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.

- **n_svd_vecs** [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to ncv when `svd_method=arpack` and n_oversamples when `svd_method` is 'randomized'.

- **mini_batch** [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

- **init** [{'k-means++', 'random'} or ndarray of (n_clusters, n_features), default='k-means++'] Method for initialization of k-means algorithm; defaults to 'k-means++'.

- **n_init** [int, default=10] Number of random initializations that are tried with the k-means algorithm.

  If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

- **n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

  None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.
**Deprecated** since version 0.23: `n_jobs` was deprecated in version 0.23 and will be removed in 0.25.

**random_state** [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See **Glossary**.

**Attributes**

- `rows_` [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. `rows[i, r]` is True if cluster i contains row r. Available only after calling `fit`.
- `columns_` [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like `rows`.
- `row_labels_` [array-like of shape (n_rows,)] Row partition labels.
- `column_labels_` [array-like of shape (n_cols,)] Column partition labels.

**Examples**

```python
>>> from sklearn.cluster import SpectralBiclustering
>>> import numpy as np

>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralBiclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 1], dtype=int32)
>>> clustering
SpectralBiclustering(n_clusters=2, random_state=0)
```

**property biclusters_**

Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

**fit**(X, y=None)

Creates a biclustering for X.

**Parameters**
X [array-like of shape (n_samples, n_features)]
y [Ignored]

get_indices (i)
Row and column indices of the i\textsuperscript{th} bicluster.
Only works if rows_ and columns_ attributes exist.

Parameters
i [int] The index of the cluster.

Returns
row_ind [ndarray, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
col_ind [ndarray, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

get_shape (i)
Shape of the i\textsuperscript{th} bicluster.

Parameters
i [int] The index of the cluster.

Returns
n_rows [int] Number of rows in the bicluster.
n_cols [int] Number of columns in the bicluster.

get_submatrix (i, data)
Return the submatrix corresponding to bicluster i.

Parameters
i [int] The index of the cluster.
data [array-like of shape (n_samples, n_features)] The data.

Returns
submatrix [ndarray of shape (n_rows, n_cols)] The submatrix corresponding to bicluster i.
Notes

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

**set_params(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.cluster.SpectralBiclustering

- A demo of the Spectral Biclustering algorithm

sklearn.cluster.SpectralCoclustering

**class sklearn.cluster.SpectralCoclustering(**kwargs**)

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array $X$ to solve the relaxed normalized cut of the bipartite graph created from $X$ as follows: the edge between row vertex $i$ and column vertex $j$ has weight $X[i, j]$.

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the User Guide.

Parameters

**n_clusters [int, default=3] The number of biclusters to find.

**svd_method [{'randomized', 'arpack'}, default='randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', use sklearn.utils.extmath.randomized_svd, which may be faster for large matrices. If 'arpack', use scipy.sparse.linalg.svds, which is more accurate, but possibly slower in some cases.

**n_svd_vecs [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to ncv when svd_method=arpack and n_oversamples when svd_method is 'randomized'.

**mini_batch [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

**init [{'k-means++', 'random', or ndarray of shape (n_clusters, n_features), default='k-means++'] Method for initialization of k-means algorithm; defaults to 'k-means++'.

**n_init [int, default=10] Number of random initializations that are tried with the k-means algorithm.
If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

**n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

 Deprecated since version 0.23: n_jobs was deprecated in version 0.23 and will be removed in 0.25.

**random_state** [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See Glossary.

**Attributes**

- **rows_** [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling fit.

- **columns_** [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like rows.

- **row_labels_** [array-like of shape (n_rows,)] The bicluster label of each row.

- **column_labels_** [array-like of shape (n_cols,)] The bicluster label of each column.

**References**

**Examples**

```python
>>> from sklearn.cluster import SpectralCoclustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralCoclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([0, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 0], dtype=int32)
>>> clustering
SpectralCoclustering(n_clusters=2, random_state=0)
```

**Methods**

- **fit(X[, y])** Creates a biclustering for X.

- **get_indices**(i) Row and column indices of the i’th bicluster.

- **get_params**(deep)

- **get_shape**(i) Shape of the i’th bicluster.

- **get_submatrix**(i, data) Return the submatrix corresponding to bicluster i.

- **set_params**(**params) Set the parameters of this estimator.
property biclusters_
    Convenient way to get row and column indicators together.
    Returns the rows_ and columns_ members.

fit (X, y=None)
    Creates a biclustering for X.

    Parameters
    X [array-like of shape (n_samples, n_features)]
    y [Ignored]

get_indices (i)
    Row and column indices of the i`th` bicluster.
    Only works if rows_ and columns_ attributes exist.

    Parameters
    i [int] The index of the cluster.

    Returns
    row_ind [ndarray, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
    col_ind [ndarray, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params (deep=True)
    Get parameters for this estimator.

    Parameters
    deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns
    params [dict] Parameter names mapped to their values.

get_shape (i)
    Shape of the i`th` bicluster.

    Parameters
    i [int] The index of the cluster.

    Returns
    n_rows [int] Number of rows in the bicluster.
    n_cols [int] Number of columns in the bicluster.

get_submatrix (i, data)
    Return the submatrix corresponding to bicluster i.

    Parameters
    i [int] The index of the cluster.
    data [array-like of shape (n_samples, n_features)] The data.

    Returns
    submatrix [ndarray of shape (n_rows, n_cols)] The submatrix corresponding to bicluster i.
Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.cluster.SpectralCoclustering

- Biclustering documents with the Spectral Co-clustering algorithm

7.3.2 Functions

```
cluster.affinity_propagation(S, *[...]) Perform Affinity Propagation Clustering of data.
cluster.cluster_optics_dbscan(*,...) Performs DBSCAN extraction for an arbitrary epsilon.
cluster.cluster_optics_xi(*, reachability, ...) Automatically extract clusters according to the Xi-steep method.
cluster.compute_optics_graph(X, *, ...) Computes the OPTICS reachability graph.
cluster.dbscan(X[, eps, min_samples, ...]) Perform DBSCAN clustering from vector array or distance matrix.
cluster.estimate_bandwidth(X, *[...], quantile, ...) Estimate the bandwidth to use with the mean-shift algorithm.
cluster.k_means(X, n_clusters, *[...]) K-means clustering algorithm.
cluster.mean_shift(X, *[...], bandwidth, seeds, ...) Perform mean shift clustering of data using a flat kernel.
cluster.spectral_clustering(affinity, *[...]) Apply clustering to a projection of the normalized Laplacian.
cluster.ward_tree(X, *[...], connectivity, ...) Ward clustering based on a Feature matrix.
```

sklearn.cluster.affinity_propagation

```
sklearn.cluster.affinity_propagation(S, *, preference=None, convergence_iter=15, max_iter=200, damping=0.5, copy=True, verbose=False, return_n_iter=False, random_state='warn')
```

Perform Affinity Propagation Clustering of data.

Read more in the User Guide.
S [array-like of shape (n_samples, n_samples)] Matrix of similarities between points.

preference [array-like of shape (n_samples,) or float, default=None] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.

convergence_iter [int, default=15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

max_iter [int, default=200] Maximum number of iterations

damping [float, default=0.5] Damping factor between 0.5 and 1.

copy [bool, default=True] If copy is False, the affinity matrix is modified inplace by the algorithm, for memory efficiency.

verbose [bool, default=False] The verbosity level.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

random_state [int, RandomState instance or None, default=0] Pseudo-random number generator to control the starting state. Use an int for reproducible results across function calls. See the Glossary.

New in version 0.23: this parameter was previously hardcoded as 0.

Returns

cluster_centers_indices [ndarray of shape (nClusters,)]: Index of clusters centers.

labels [ndarray of shape (n_samples,)]: Cluster labels for each point.

n_iter [int]: Number of iterations run. Returned only if return_n_iter is set to True.

Notes

For an example, see examples/cluster/plot_affinity_propagation.py.

When the algorithm does not converge, it returns an empty array as cluster_center_indices and -1 as label for each training sample.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, a single cluster center and label 0 for every sample will be returned. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

References

Examples using `sklearn.cluster.affinity_propagation`

- Visualizing the stock market structure

`sklearn.cluster.cluster_optics_dbscan`

`sklearn.cluster.cluster_optics_dbscan(*, reachability, core_distances, ordering, eps)`

Performs DBSCAN extraction for an arbitrary epsilon.

Extracting the clusters runs in linear time. Note that this results in `labels_` which are close to a DBSCAN with similar settings and `eps`, only if `eps` is close to `max_eps`.

**Parameters**

- **reachability** [array of shape (n_samples,)] Reachability distances calculated by OPTICS
  `(reachability_)`
- **core_distances** [array of shape (n_samples,)] Distances at which points become core
  `(core_distances_)`
- **ordering** [array of shape (n_samples,)] OPTICS ordered point indices `(ordering_)`
- **eps** [float] DBSCAN `eps` parameter. Must be set to < `max_eps`. Results will be close to DBSCAN algorithm if `eps` and `max_eps` are close to one another.

**Returns**

- **labels_** [array of shape (n_samples,)] The estimated labels.

Examples using `sklearn.cluster.cluster_optics_dbscan`

- Demo of OPTICS clustering algorithm

`sklearn.cluster.cluster_optics_xi`

`sklearn.cluster.cluster_optics_xi(*, reachability, predecessor, ordering, min_samples, min_cluster_size=None, xi=0.05, predecessor_correction=True)`

Automatically extract clusters according to the Xi-steep method.

**Parameters**

- **reachability** [ndarray of shape (n_samples,)] Reachability distances calculated by OPTICS
  `(reachability_)`
- **predecessor** [ndarray of shape (n_samples,)] Predecessors calculated by OPTICS.
- **ordering** [ndarray of shape (n_samples,)] OPTICS ordered point indices `(ordering_)`
- **min_samples** [int > 1 or float between 0 and 1] The same as the min_samples given to OPTICS.
  Up and down steep regions can’t have more then `min_samples` consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).
- **min_cluster_size** [int > 1 or float between 0 and 1, default=None] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If `None`, the value of `min_samples` is used instead.
xi [float between 0 and 1, default=0.05] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi.

predecessor_correction [bool, default=True] Correct clusters based on the calculated predecessors.

Returns

labels [ndarray of shape (n_samples,)] The labels assigned to samples. Points which are not included in any cluster are labeled as -1.

clusters [ndarray of shape (n_clusters, 2)] The list of clusters in the form of [start, end] in each row, with all indices inclusive. The clusters are ordered according to (end, -start) (ascending) so that larger clusters encompassing smaller clusters come after such nested smaller clusters. Since labels does not reflect the hierarchy, usually len(clusters) > np.unique(labels).

sklearn.cluster.compute_optics_graph

sklearn.cluster.compute_optics_graph (X, *, min_samples, max_eps, metric, p, metric_params, algorithm, leaf_size, n_jobs)

Computes the OPTICS reachability graph.

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples, n_features), or (n_samples, n_samples) if metric=’precomputed’] A feature array, or array of distances between samples if metric=’precomputed’

min_samples [int > 1 or float between 0 and 1] The number of samples in a neighborhood for a point to be considered as a core point. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

max_eps [float, default=np.inf] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of np.inf will identify clusters across all scales; reducing max_eps will result in shorter run times.

metric [str or callable, default=’minkowski’] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used. If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string. If metric is “precomputed”, X is assumed to be a distance matrix and must be square.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.
p [int, default=2] Parameter for the Minkowski metric from `pairwise_distances`. When
p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p
= 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

algorithm [['auto', 'ball_tree', 'kd_tree', 'brute'], default='auto'] Algorithm used to compute
the nearest neighbors:
  • 'ball_tree' will use BallTree
  • 'kd_tree' will use KDTree
  • 'brute' will use a brute-force search.
  • 'auto' will attempt to decide the most appropriate algorithm based on the values passed
to `fit` method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the
speed of the construction and query, as well as the memory required to store the tree. The
optimal value depends on the nature of the problem.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None
means 1 unless in a `joblib.parallel_backend` context. -1 means using all proces-
sors. See `Glossary` for more details.

Returns

ordering_ [array of shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [array of shape (n_samples,)] Distance at which each sample becomes a core
point, indexed by object order. Points which will never be core have a distance of inf. Use
clust.core_distances_[clust.ordering_] to access in cluster order.

reachability_ [array of shape (n_samples,)] Reachability distances per sample, indexed by ob-
ject order. Use clust.reachability_[clust.ordering_] to access in cluster order.

predecessor_ [array of shape (n_samples,)] Point that a sample was reached from, indexed by
object order. Seed points have a predecessor of -1.

References

[1]

sklearn.cluster.dbscan

`sklearn.cluster.dbscan(X, eps=0.5, *, min_samples=5, metric='minkowski', metric_params=None, algorithm='auto', leaf_size=30, p=2, sample_weight=None, n_jobs=None)`

Perform DBSCAN clustering from vector array or distance matrix.

Read more in the `User Guide`.

Parameters

X [[array-like, sparse (CSR) matrix] of shape (n_samples, n_features) or (n_samples, n_samples)] A feature array, or array of distances between samples if
metric='precomputed'.
**eps** [float, default=0.5] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

**min_samples** [int, default=5] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

**metric** [str or callable, default=’minkowski’] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by sklearn.metrics.pairwise_distances for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

**metric_params** [dict, default=None] Additional keyword arguments for the metric function. New in version 0.19.

**algorithm** [{'auto', ‘ball_tree’, ‘kd_tree’, ‘brute’}, default='auto'] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

**leaf_size** [int, default=30] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [float, default=2] The power of the Minkowski metric to be used to calculate distance between points.

**sample_weight** [array-like of shape (n_samples,), default=None] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

**n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. If precomputed distance are used, parallel execution is not available and thus n_jobs will have no effect.

**Returns**

- **core_samples** [ndarray of shape (n_core_samples,)] Indices of core samples.
- **labels** [ndarray of shape (n_samples,)] Cluster labels for each point. Noisy samples are given the label -1.

**See also:**

**DBSCAN** An estimator interface for this clustering algorithm.

**OPTICS** A similar estimator interface clustering at multiple values of eps. Our implementation is optimized for memory usage.
Notes

For an example, see examples/cluster/plot_dbscan.py.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n). It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using NearestNeighbors.radius_neighbors_graph with mode='distance', then using metric='precomputed' here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use sample_weight instead.

cluster.optics provides a similar clustering with lower memory usage.

References

sklearn.cluster.estimate_bandwidth

sklearn.cluster.estimate_bandwidth(X, *, quantile=0.3, n_samples=None, random_state=0, n_jobs=None)

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in n_samples. For large datasets, it’s wise to set that parameter to a small value.

Parameters

- X [array-like of shape (n_samples, n_features)] Input points.
- quantile [float, default=0.3] should be between [0, 1] 0.5 means that the median of all pairwise distances is used.
- n_samples [int, default=None] The number of samples to use. If not given, all samples are used.
- random_state [int, RandomState instance, default=None] The generator used to randomly select the samples from input points for bandwidth estimation. Use an int to make the randomness deterministic. See Glossary.
- n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

- bandwidth [float] The bandwidth parameter.
Examples using sklearn.cluster.estimate_bandwidth

- A demo of the mean-shift clustering algorithm
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.k_means

sklearn.cluster.k_means(X, n_clusters, *, sample_weight=None, init='k-means++', precompute_distances='deprecated', n_init=10, max_iter=300, verbose=False, tol=0.0001, random_state=None, copy_x=True, n_jobs='deprecated', algorithm='auto', return_n_iter=False)

K-means clustering algorithm.

Read more in the User Guide.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) The observations to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.
- **n_clusters** [int] The number of clusters to form as well as the number of centroids to generate.
- **sample_weight** [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.
- **init** [‘k-means++’, ‘random’], callable or array-like of shape (n_clusters, n_features), default=’k-means++’ Method for initialization:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose n_clusters observations (rows) at random from data for the initial centroids.
  - If an array is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
  - If a callable is passed, it should take arguments X, n_clusters and a random state and return an initialization.
- **precompute_distances** [‘auto’, True, False] Precompute distances (faster but takes more memory).
  - ‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
  - True : always precompute distances
  - False : never precompute distances
  - Deprecated since version 0.23: ‘precompute_distances’ was deprecated in version 0.23 and will be removed in 0.25. It has no effect.
- **n_init** [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- **max_iter** [int, default=300] Maximum number of iterations of the k-means algorithm to run.
- **verbose** [bool, default=False] Verbosity mode.
tol [float, default=1e-4] Relative tolerance with regards to Frobenius norm of the difference in the cluster centers of two consecutive iterations to declare convergence.

random_state [int, RandomState instance or None, default=None] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See Glossary.

copy_x [bool, default=True] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True (default), then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean. Note that if the original data is not C-contiguous, a copy will be made even if copy_x is False. If the original data is sparse, but not in CSR format, a copy will be made even if copy_x is False.

n_jobs [int, default=None] The number of OpenMP threads to use for the computation. Parallelism is sample-wise on the main cython loop which assigns each sample to its closest center.

None or -1 means using all processors.

Deprecated since version 0.23: n_jobs was deprecated in version 0.23 and will be removed in 0.25.

algorithm [{"auto", “full”, “elkan"}, default=”auto"] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient on data with well-defined clusters, by using the triangle inequality. However it’s more memory intensive due to the allocation of an extra array of shape (n_samples, n_clusters).

For now “auto” (kept for backward compatibility) chooses “elkan” but it might change in the future for a better heuristic.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

Returns

centroid [ndarray of shape (n_clusters, n_features)] Centroids found at the last iteration of k-means.

label [ndarray of shape (n_samples,)] label[i] is the code or index of the centroid the i'th observation is closest to.

inertia [float] The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

best_n_iter [int] Number of iterations corresponding to the best results. Returned only if return_n_iter is set to True.

sklearn.cluster.mean_shift

sklearn.cluster.mean_shift(X, *, bandwidth=None, seeds=None, bin_seeding=False, min_bin_freq=1, cluster_all=True, max_iter=300, n_jobs=None)

Perform mean shift clustering of data using a flat kernel.

Read more in the User Guide.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

bandwidth [float, default=None] Kernel bandwidth.
If bandwidth is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The sklearn.cluster.estimate_bandwidth function can be used to do this more efficiently.

**seeds** [array-like of shape (n_seeds, n_features) or None] Point used as initial kernel locations. If None and bin_seeding=False, each data point is used as a seed. If None and bin_seeding=True, see bin_seeding.

**bin_seeding** [bool, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if seeds argument is not None.

**min_bin_freq** [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

**cluster_all** [bool, default=True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

**max_iter** [int, default=300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

**n_jobs** [int, default=None] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.17: Parallel Execution using n_jobs.

**Returns**

- **cluster_centers** [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers.
- **labels** [ndarray of shape (n_samples,)] Cluster labels for each point.

**Notes**

For an example, see examples/cluster/plot_mean_shift.py.

### sklearn.cluster.spectral_clustering

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance, when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the User Guide.

**Parameters**

- **affinity** [(array-like, sparse matrix)] of shape (n_samples, n_samples) The affinity matrix describing the relationship of the samples to embed. Must be symmetric.
Possible examples:
- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,
- symmetric k-nearest neighbours connectivity matrix of the samples.

**n_clusters** [int, default=None] Number of clusters to extract.

**n_components** [int, default=n_clusters] Number of eigen vectors to use for the spectral embedding.

**eigen_solver** [None, ‘arpack’, ‘lobpcg’, or ‘amg’] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities. If None, then ‘arpack’ is used.

**random_state** [int, RandomState instance, default=None] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == ‘amg’ and by the K-Means initialization. Use an int to make the randomness deterministic. See Glossary.

**n_init** [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

**eigen_tol** [float, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

**assign_labels** [‘kmeans’, ‘discretize’, default=’kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the ‘Multiclass spectral clustering’ paper referenced below for more details on the discretization approach.

**verbose** [bool, default=False] Verbosity mode.

New in version 0.24.

**Returns**

**labels** [array of integers, shape: n_samples] The labels of the clusters.

**Notes**

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for k=2: it is a normalized spectral clustering.

**References**

Examples using `sklearn.cluster.spectral_clustering`

- Segmenting the picture of greek coins in regions
- Spectral clustering for image segmentation

`sklearn.cluster.ward_tree`

`sklearn.cluster.ward_tree(X, *, connectivity=None, n_clusters=None, return_distance=False)`

Ward clustering based on a Feature matrix.

Recursively merges the pair of clusters that minimally increases within-cluster variance.

The inertia matrix uses a Heapq-based representation.

This is the structured version, that takes into account some topological structure between samples.

Read more in the User Guide.

Parameters

- `X` [array-like of shape (n_samples, n_features)] feature matrix representing n_samples samples to be clustered
- `connectivity` [sparse matrix, default=None] connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e, the Ward algorithm is unstructured.
- `n_clusters` [int, default=None] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the ‘children’ output is of limited use, and the ‘parents’ output should rather be used. This option is valid only when specifying a connectivity matrix.
- `return_distance` [bool, default=None] If True, return the distance between the clusters.

Returns

- `children` [ndarray of shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children[i - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i
- `n_connected_components` [int] The number of connected components in the graph.
- `n_leaves` [int] The number of leaves in the tree
- `parents` [ndarray of shape (n_nodes,) or None] The parent of each node. Only returned when a connectivity matrix is specified, elsewhere ‘None’ is returned.
- `distances` [ndarray of shape (n_nodes-1,)] Only returned if return_distance is set to True (for compatibility). The distances between the centers of the nodes. distances[i] corresponds to a weighted euclidean distance between the nodes children[i, 1] and children[i, 2]. If the nodes refer to leaves of the tree, then distances[i] is their unweighted euclidean distance. Distances are updated in the following way (from scipy.hierarchy.linkage):

7.3. `sklearn.cluster`: Clustering
The new entry \( d(u, v) \) is computed as follows,

\[
d(u, v) = \sqrt{\frac{|v| + |s|}{T} d(v, s)^2 + \frac{|v| + |t|}{T} d(v, t)^2 - \frac{|v|}{T} d(s, t)^2}
\]

where \( u \) is the newly joined cluster consisting of clusters \( s \) and \( t \), \( v \) is an unused cluster in the forest, \( T = |v| + |s| + |t| \), and \(|*|\) is the cardinality of its argument. This is also known as the incremental algorithm.

### 7.4 sklearn.compose: Composite Estimators

Meta-estimators for building composite models with transformers

In addition to its current contents, this module will eventually be home to refurbished versions of Pipeline and FeatureUnion.

**User guide:** See the Pipelines and composite estimators section for further details.

#### 7.4.1 sklearn.compose.ColumnTransformer

**class** sklearn.compose.ColumnTransformer(**kwargs)**
Applies transformers to columns of an array or pandas DataFrame.

This estimator allows different columns or column subsets of the input to be transformed separately and the features generated by each transformer will be concatenated to form a single feature space. This is useful for heterogeneous or columnar data, to combine several feature extraction mechanisms or transformations into a single transformer.

Read more in the User Guide.

New in version 0.20.

**Parameters**

- **transformers** [list of tuples] List of (name, transformer, columns) tuples specifying the transformer objects to be applied to subsets of the data.
- **name** [str] Like in Pipeline and FeatureUnion, this allows the transformer and its parameters to be set using `set_params` and searched in grid search.
- **transformer** [{‘drop’, ‘passthrough’} or estimator] Estimator must support `fit` and `transform`. Special-cased strings ‘drop’ and ‘passthrough’ are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.
- **columns** [str, array-like of str, int, array-like of int, array-like of bool, slice or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where `transformer` expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data X and can return any of the above. To select multiple columns by name or dtype, you can use `make_column_selector`.
remainder [\{'drop', 'passthrough'\} or estimator, default='drop'] By default, only the specified columns in transformers are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying remainder='passthrough', all remaining columns that were not specified in transformers will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting remainder to be an estimator, the remaining non-specified columns will use the remainder estimator. The estimator must support fit and transform. Note that using this feature requires that the DataFrame columns input at fit and transform have identical order.

sparse_threshold [float, default=0.3] If the output of the different transformers contains sparse matrices, these will be stacked as a sparse matrix if the overall density is lower than this value. Use sparse_threshold=0 to always return dense. When the transformed output consists of all dense data, the stacked result will be dense, and this keyword will be ignored.

n_jobs [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

transformer_weights [dict, default=None] Multiplicative weights for features per transformer. The output of the transformer is multiplied by these weights. Keys are transformer names, values the weights.

verbose [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

Attributes

transformers_ [list] The collection of fitted transformers as tuples of (name, fitted_transformer, column). fitted_transformer can be an estimator, 'drop', or 'passthrough'. In case there were no columns selected, this will be the unfitted transformer. If there are remaining columns, the final element is a tuple of the form: (remainder, transformer, remaining_columns) corresponding to the remainder parameter. If there are remaining columns, then len(transformers_)==len(transformers)+1, otherwise len(transformers_)==len(transformers).

named_transformers_ [Bunch] Access the fitted transformer by name.

sparse_output_ [bool] Boolean flag indicating whether the output of transform is a sparse matrix or a dense numpy array, which depends on the output of the individual transformers and the sparse_threshold keyword.

See also:

make_column_transformer
Convenience function for combining the outputs of multiple transformer objects applied to column subsets of the original feature space.

make_column_selector
Convenience function for selecting columns based on datatype or the columns name with a regex pattern.
Notes

The order of the columns in the transformed feature matrix follows the order of how the columns are specified in the transformers list. Columns of the original feature matrix that are not specified are dropped from the resulting transformed feature matrix, unless specified in the passthrough keyword. Those columns specified with passthrough are added at the right to the output of the transformers.

Examples

```python
>>> import numpy as np
>>> from sklearn.compose import ColumnTransformer
>>> from sklearn.preprocessing import Normalizer

>>> ct = ColumnTransformer(  ...
         [('norm1', Normalizer(norm='l1'), [0, 1]),  ...
         ('norm2', Normalizer(norm='l1'), slice(2, 4))])

>>> X = np.array([[0., 1., 2., 2.],  ...
                [1., 1., 0., 1.]])

>>> # Normalizer scales each row of X to unit norm. A separate scaling  ...
>>> # is applied for the two first and two last elements of each  ...
>>> # row independently.
>>> ct.fit_transform(X)
array([[0. , 1. , 0.5, 0.5],  ...
       [0.5, 0.5, 0. , 1. ]])
```

Methods

```python
fit(X, y=None) Fit all transformers using X.
fit_transform(X, y=None) Fit all transformers, transform the data and concatenate results.
get_feature_names() Get feature names from all transformers.
get_params([deep]) Get parameters for this estimator.
set_params(**kwargs) Set the parameters of this estimator.
transform(X) Transform X separately by each transformer, concatenate results.
```

```python
fit (X, y=None)
Fit all transformers using X.

Parameters

X [[array-like, dataframe] of shape (n_samples, n_features)] Input data, of which specified subsets are used to fit the transformers.

y [array-like of shape (n_samples,...), default=None] Targets for supervised learning.

Returns

self [ColumnTransformer] This estimator

fit_transform (X, y=None)
Fit all transformers, transform the data and concatenate results.

Parameters

X [[array-like, dataframe] of shape (n_samples, n_features)] Input data, of which specified subsets are used to fit the transformers.
```
y [array-like of shape (n_samples,), default=None] Targets for supervised learning.

Returns

X_t [(array-like, sparse matrix) of shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

get_feature_names ()
Get feature names from all transformers.

Returns

feature_names [list of strings] Names of the features produced by transform.

get_params (deep=True)
Get parameters for this estimator.

Returns the parameters given in the constructor as well as the estimators contained within the transformers of the ColumnTransformer.

Parameters

dee [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property named_transformers_
Access the fitted transformer by name.

Read-only attribute to access any transformer by given name. Keys are transformer names and values are the fitted transformer objects.

set_params (**kwargs)
Set the parameters of this estimator.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in transformers of ColumnTransformer.

Returns

self

transform (X)
Transform X separately by each transformer, concatenate results.

Parameters

X [(array-like, dataframe) of shape (n_samples, n_features)] The data to be transformed by subset.

Returns

X_t [(array-like, sparse matrix) of shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.
Examples using `sklearn.compose.ColumnTransformer`

- Poisson regression and non-normal loss
- Tweedie regression on insurance claims
- Permutation Importance vs Random Forest Feature Importance (MDI)
- Column Transformer with Mixed Types
- Column Transformer with Heterogeneous Data Sources

### 7.4.2 `sklearn.compose.TransformedTargetRegressor`

**Class `sklearn.compose.TransformedTargetRegressor(**kwargs)`**

Meta-estimator to regress on a transformed target.

Useful for applying a non-linear transformation to the target \( y \) in regression problems. This transformation can be given as a Transformer such as the QuantileTransformer or as a function and its inverse such as \( \log \) and \( \exp \).

The computation during `fit` is:

```
regressor.fit(X, func(y))
```

or:

```
regressor.fit(X, transformer.transform(y))
```

The computation during `predict` is:

```
inverse_func(regressor.predict(X))
```

or:

```
transformer.inverse_transform(regressor.predict(X))
```

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

- **regressor** [object, default=None] Regressor object such as derived from `RegressorMixin`. This regressor will automatically be cloned each time prior to fitting. If regressor is None, `LinearRegression()` is created and used.

- **transformer** [object, default=None] Estimator object such as derived from `TransformerMixin`. Cannot be set at the same time as `func` and `inverse_func`. If transformer is None as well as `func` and `inverse_func`, the transformer will be an identity transformer. Note that the transformer will be cloned during fitting. Also, the transformer is restricting \( y \) to be a numpy array.

- **func** [function, default=None] Function to apply to \( y \) before passing to `fit`. Cannot be set at the same time as `transformer`. The function needs to return a 2-dimensional array. If `func` is None, the function used will be the identity function.

- **inverse_func** [function, default=None] Function to apply to the prediction of the regressor. Cannot be set at the same time as `transformer` as well. The function needs to return
a 2-dimensional array. The inverse function is used to return predictions to the same space of the original training labels.

**check_inverse** [bool, default=True] Whether to check that transform followed by inverse_transform or func followed by inverse_func leads to the original targets.

**Attributes**

- **regressor_** [object] Fitted regressor.
- **transformer_** [object] Transformer used in fit and predict.

**Notes**

Internally, the target $y$ is always converted into a 2-dimensional array to be used by scikit-learn transformers. At the time of prediction, the output will be reshaped to have the same number of dimensions as $y$.

See examples/compose/plot_transformed_target.py.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.compose import TransformedTargetRegressor

>>> tt = TransformedTargetRegressor(regressor=LinearRegression(),
...                                 func=np.log, inverse_func=np.exp)

>>> X = np.arange(4).reshape(-1, 1)
>>> y = np.exp(2 * X).ravel()

>>> tt.fit(X, y)
TransformedTargetRegressor(...)

>>> tt.score(X, y)
1.0

>>> tt.regressor_.coef_
array([2.])
```

**Methods**

- **fit**(X, y, **fit_params)** Fit the model according to the given training data.
- **get_params**(deep)
- **predict**(X)
- **score**(X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.
- **set_params**(**params)** Set the parameters of this estimator.

```python
>>> fit (X, y, **fit_params)
Fit the model according to the given training data.
```

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values.
**fit_params** [dict] Parameters passed to the fit method of the underlying regressor.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict using the base regressor, applying inverse.

The regressor is used to predict and the inverse_func or inverse_transform is applied before returning the prediction.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Samples.

Returns

y_hat [ndarray of shape (n_samples,)] Predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y\_true - y\_pred)^2).sum()$ and $v$ is the total sum of squares $((y\_true - y\_true.mean())^2).sum()$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params(**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.compose.TransformedTargetRegressor`

- Poisson regression and non-normal loss
- Common pitfalls in interpretation of coefficients of linear models
- Effect of transforming the targets in regression model

```python
compose.make_column_transformer(*transformers) Construct a ColumnTransformer from the given transformers.

compose.make_column_selector(**kwargs) Create a callable to select columns to be used with ColumnTransformer.
```

7.4.3 `sklearn.compose.make_column_transformer`

`sklearn.compose.make_column_transformer(*transformers, remainder='drop', sparse_threshold=0.3, n_jobs=None, verbose=False)`

Construct a ColumnTransformer from the given transformers.

This is a shorthand for the ColumnTransformer constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting with `transformer_weights`.

Read more in the User Guide.

Parameters

*transformers [tuples] Tuples of the form (transformer, columns) specifying the transformer objects to be applied to subsets of the data.

transformer [[‘drop’, ‘passthrough’] or estimator] Estimator must support `fit` and `transform`. Special-cased strings ‘drop’ and ‘passthrough’ are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.

columns [str, array-like of str, int, array-like of int, slice, array-like of bool or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be
used where transformer expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data X and can return any of the above. To select multiple columns by name or dtype, you can use make_column_selector.

**remainder** [{’drop’, ’passthrough’} or estimator, default=’drop’] By default, only the specified columns in transformers are transformed and combined in the output, and the non-specified columns are dropped. (default of ’drop’). By specifying remainder=’passthrough’, all remaining columns that were not specified in transformers will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting remainder to be an estimator, the remaining non-specified columns will use the remainder estimator. The estimator must support fit and transform.

**sparse_threshold** [float, default=0.3] If the transformed output consists of a mix of sparse and dense data, it will be stacked as a sparse matrix if the density is lower than this value. Use sparse_threshold=0 to always return dense. When the transformed output consists of all sparse or all dense data, the stacked result will be sparse or dense, respectively, and this keyword will be ignored.

**n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**verbose** [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Returns**

c
t [ColumnTransformer]

**See also:**

**ColumnTransformer** Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

**Examples**

```python
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer

make_column_transformer(
    ...
    (StandardScaler(), ['numerical_column']),
    ...
    (OneHotEncoder(), ['categorical_column'])
)
ColumnTransformer(transformers=[
    ('standardscaler', StandardScaler(...),
    ['numerical_column']),
    ('onehotencoder', OneHotEncoder(...),
    ['categorical_column'])
])
```
Examples using `sklearn.compose.make_column_transformer`

- Release Highlights for scikit-learn 0.23
- Combine predictors using stacking
- Common pitfalls in interpretation of coefficients of linear models

### 7.4.4 `sklearn.compose.make_column_selector`

`make_column_selector` can select columns based on datatype or the columns name with a regex. When using multiple selection criteria, all criteria must match for a column to be selected.

**Parameters**

- `pattern` [str, default=None] Name of columns containing this regex pattern will be included. If None, column selection will not be selected based on pattern.
- `dtype_include` [column dtype or list of column dtypes, default=None] A selection of dtypes to include. For more details, see pandas.DataFrame.select_dtypes.
- `dtype_exclude` [column dtype or list of column dtypes, default=None] A selection of dtypes to exclude. For more details, see pandas.DataFrame.select_dtypes.

**Returns**

- `selector` [callable] Callable for column selection to be used by a `ColumnTransformer`.

**See also:**

- `ColumnTransformer` Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

#### Examples

```python
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> from sklearn.compose import make_column_selector
>>> import pandas as pd

>>> X = pd.DataFrame({'city': ['London', 'London', 'Paris', 'Sallisaw'], 'rating': [5, 3, 4, 5]})

>>> ct = make_column_transformer((StandardScaler(), make_column_selector(dtype_include=np.number)),  # rating
... (OneHotEncoder(), make_column_selector(dtype_include=object)))  # city

>>> ct.fit_transform(X)
array([[ 0.90453403, 1., 0., 0. ],
       [-1.50755672, 1., 0., 0. ],
       [-0.30151134, 0., 1., 0. ],
       [ 0.90453403, 0., 0., 1. ]])
```
Examples using `sklearn.compose.make_column_selector`

- Column Transformer with Mixed Types

## 7.5 sklearn.covariance: Covariance Estimators

The `sklearn.covariance` module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance estimation is closely related to the theory of Gaussian Graphical Models.

**User guide:** See the *Covariance estimation* section for further details.

### 7.5.1 sklearn.covariance.EmpiricalCovariance

**class** `sklearn.covariance.EmpiricalCovariance(**kwargs)`

Maximum likelihood covariance estimator

Read more in the *User Guide*.

**Parameters**

- **store_precision** [bool, default=True] Specifies if the estimated precision is stored.
- **assume_centered** [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

**Attributes**

- **location_** [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
- **covariance_** [ndarray of shape (n_features, n_features)] Estimated covariance matrix
- **precision_** [ndarray of shape (n_features, n_features)] Estimated pseudo-inverse matrix. (stored only if store_precision is True)
Examples

```python
>>> import numpy as np
dev0
>>> from sklearn.covariance import EmpiricalCovariance
>>> from sklearn.datasets import make_gaussian_quantiles

real_cov = np.array([[.8, .3],
                     [.3, .4]])

rng = np.random.RandomState(0)

X = rng.multivariate_normal(mean=[0, 0],
                            cov=real_cov,
                            size=500)

cov = EmpiricalCovariance().fit(X)

cov.covariance_
array([[0.7569..., 0.2818...],
       [0.2818..., 0.3928...]])

cov.location_
array([0.0622..., 0.0193...])
```

**error_norm**

```
error_norm(comp_cov[, norm, scaling, squared])
```

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- `comp_cov` [array-like of shape (n_features, n_features)] The covariance to compare with.
- `norm` [“frobenius”, “spectral”, default=”frobenius”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).
- `scaling` [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- `squared` [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**
result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

Parameters
X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [Ignored] Not used, present for API consistence purpose.

Returns
self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters
dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns
precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters
X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns
dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters
X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).
y [Ignored] Not used, present for API consistence purpose.

Returns
res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.covariance.EmpiricalCovariance

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate

7.5.2 sklearn.covariance.EllipticEnvelope

class sklearn.covariance.EllipticEnvelope(**kwargs)
An object for detecting outliers in a Gaussian distributed dataset.

Read more in the User Guide.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction [float, default=None] The proportion of points to be included in the support of the raw MCD estimate. If None, the minimum value of support_fraction will be used within the algorithm: \(\frac{n_{\text{sample}} + n_{\text{features}} + 1}{2}\). Range is (0, 1).

contamination [float, default=0.1] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Range is (0, 0.5).

random_state [int, RandomState instance or None, default=None] Determines the pseudo random number generator for shuffling the data. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

Attributes

location_ [ndarray of shape (n_features,)] Estimated robust location.

covariance_ [ndarray of shape (n_features, n_features)] Estimated robust covariance matrix.

precision_ [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
**support_** [ndarray of shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

**offset_** [float] Offset used to define the decision function from the raw scores. We have the relation: \( \text{decision\_function} = \text{score\_samples} - \text{offset\_} \). The offset depends on the contamination parameter and is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training.

New in version 0.20.

**raw\_location_** [ndarray of shape (n_features,)] The raw robust estimated location before correction and re-weighting.

**raw\_covariance_** [ndarray of shape (n_features, n_features)] The raw robust estimated covariance before correction and re-weighting.

**raw\_support_** [ndarray of shape (n_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

**dist_** [ndarray of shape (n_samples,)] Mahalanobis distances of the training set (on which \( \text{fit} \) is called) observations.

See also:

*EmpiricalCovariance*, *MinCovDet*

**Notes**

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In particular, one will always take care to work with \( n\_\text{samples} > n\_\text{features} \times \text{**2} \).

**References**

[1]

**Examples**

```python
>>> import numpy as np
>>> from sklearn.covariance import EllipticEnvelope
>>> true_cov = np.array([[.8, .3],
...                      [.3, .4]])
>>> X = np.random.RandomState(0).multivariate_normal(mean=[0, 0],
...                                                cov=true_cov,
...                                                size=500)
>>> cov = EllipticEnvelope(random_state=0).fit(X)
>>> # predict returns 1 for an inlier and -1 for an outlier
>>> cov.predict([[0, 0],
...               [3, 3]])
array([[ 1, -1]])
>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])
>>> cov.location_
array([0.0813..., 0.0427...])
```
Methods

correct_covariance(data)  Apply a correction to raw Minimum Covariance Determinant estimates.

decision_function(X)  Compute the decision function of the given observations.

error_norm(comp_cov[, norm, scaling, squared])  Computes the Mean Squared Error between two covariance estimators.

fit(X[, y])  Fit the EllipticEnvelope model.

fit_predict(X[, y])  Perform fit on X and returns labels for X.

get_params([deep])  Get parameters for this estimator.

get_precision()  Getter for the precision matrix.

mahalanobis(X)  Computes the squared Mahalanobis distances of given observations.

predict(X)  Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.

reweight_covariance(data)  Re-weight raw Minimum Covariance Determinant estimates.

score(X, y[, sample_weight])  Returns the mean accuracy on the given test data and labels.

score_samples(X)  Compute the negative Mahalanobis distances.

set_params(**params)  Set the parameters of this estimator.

correct_covariance(data)
    Apply a correction to raw Minimum Covariance Determinant estimates.
    Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

    Parameters
    data  [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

    Returns
    covariance_corrected  [ndarray of shape (n_features, n_features)] Corrected robust covariance estimate.

References

[RVD]

decision_function(X)
    Compute the decision function of the given observations.

    Parameters
    X  [array-like of shape (n_samples, n_features)] The data matrix.

    Returns
    decision  [ndarray of shape (n_samples,)] Decision function of the samples. It is equal to the shifted Mahalanobis distances. The threshold for being an outlier is 0, which ensures a compatibility with other outlier detection algorithms.
error_norm(comp_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm ["frobenius", "spectral", default="frobenius"] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit(X, y=None)

Fit the EllipticEnvelope model.

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) Training data.

y [Ignored] Not used, present for API consistency by convention.

fit_predict(X, y=None)

Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

Parameters

X [array-like, sparse matrix, dataframe] of shape (n_samples, n_features)]

y [Ignored] Not used, present for API consistency by convention.

Returns

y [ndarray of shape (n_samples,)] 1 for inliers, -1 for outliers.

get_params(deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision()

Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.
**mahalanobis** *(X)*
Computes the squared Mahalanobis distances of given observations.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- **dist** [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

**predict** *(X)*
Predict the labels (1 inlier, -1 outlier) of *X* according to the fitted model.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data matrix.

**Returns**

- **is_inlier** [ndarray of shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

**reweight_covariance** *(data)*
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

**Parameters**

- **data** [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **location_reweighted** [ndarray of shape (n_features,)] Re-weighted robust location estimate.
- **covariance_reweighted** [ndarray of shape (n_features, n_features)] Re-weighted robust covariance estimate.
- **support_reweighted** [ndarray of shape (n_samples,), dtype=bool] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

**References**

[RVDriessen]

**score** *(X, y, sample_weight=None)*
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for *X*.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
Returns

score [float] Mean accuracy of self.predict(X) w.r.t. y.

score_samples (X)
Compute the negative Mahalanobis distances.

Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

negative_mahal_distances [array-like of shape (n_samples,)] Opposite of the Mahalanobis distances.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.covariance.EllipticEnvelope`

- Outlier detection on a real data set
- Comparing anomaly detection algorithms for outlier detection on toy datasets

7.5.3 sklearn.covariance.GraphicalLasso

class sklearn.covariance.GraphicalLasso(**kwargs)
Sparse inverse covariance estimation with an l1-penalized estimator.

Read more in the User Guide.

Changed in version v0.20: GraphLasso has been renamed to GraphicalLasso

Parameters

alpha [float, default=0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance. Range is (0, inf].

mode [‘cd’, ‘lars’], default=’cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [float, default=1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped. Range is (0, inf].

enet_tol [float, default=1e-4] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode=’cd’. Range is (0, inf].
max_iter  [int, default=100] The maximum number of iterations.

verbose  [bool, default=False] If verbose is True, the objective function and dual gap are plotted at each iteration.

assume_centered  [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_  [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_  [ndarray of shape (n_features, n_features)] Estimated covariance matrix

precision_  [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix.

n_iter_  [int] Number of iterations run.

graphical_lasso, GraphicalLassoCV

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLasso
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                       [0.0, 0.4, 0.0, 0.0],
...                       [0.2, 0.0, 0.3, 0.1],
...                       [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                     cov=true_cov,
...                                     size=200)
>>> cov = GraphicalLasso().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.049, 0.218, 0.019],
       [0.049, 0.364, 0.017, 0.034],
       [0.218, 0.017, 0.322, 0.093],
       [0.019, 0.034, 0.093, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.040, 0.038, 0.143])
```

**error_norm** (*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

*comp_cov* [array-like of shape (n_features, n_features)] The covariance to compare with.

*norm* [(“frobenius”, “spectral”), default=”frobenius”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

*scaling* [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

*squared* [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

*result* [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

**fit** (*X*, *y=None*)

Fits the GraphicalLasso model to X.

**Parameters**

*X* [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate

*y* [Ignored] Not used, present for API consistence purpose.

**Returns**

*self* [object]

**get_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [dict] Parameter names mapped to their values.

**get_precision** ()

Getter for the precision matrix.

**Returns**

*precision_* [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.
mahalanobis \((X)\)
Computes the squared Mahalanobis distances of given observations.

**Parameters**

- \(X\) [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score \((X_{\text{test}}, y=None)\)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

**Parameters**

- \(X_{\text{test}}\) [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. \(X_{\text{test}}\) is assumed to be drawn from the same distribution than the data used in fit (including centering).

- y [Ignored] Not used, present for API consistence purpose.

**Returns**

- res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params [dict]** Estimator parameters.

**Returns**

### 7.5.4 sklearn.covariance.GraphicalLassoCV

**class** sklearn.covariance.GraphicalLassoCV (**kwargs)**
Sparse inverse covariance w/ cross-validated choice of the l1 penalty.

See glossary entry for **cross-validation estimator**.

Read more in the User Guide.

Changed in version v0.20: GraphLassoCV has been renamed to GraphicalLassoCV

**Parameters**

- alphas [int or array-like of shape (n_alphas,), dtype=float, default=4] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details. Range is (0, inf] when floats given.
n_refinements [int, default=4] The number of times the grid is refined. Not used if explicit values of alphas are passed. Range is [1, inf).

cv [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  • None, to use the default 5-fold cross-validation,
  • integer, to specify the number of folds.
  • CV splitter,
  • An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.20: cv default value if None changed from 3-fold to 5-fold.

tol [float, default=1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped. Range is (0, inf].

enet_tol [float, default=1e-4] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'. Range is (0, inf].

max_iter [int, default=100] Maximum number of iterations.

mode [{‘cd’, ‘lars’}, default=’cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer cd which is more numerically stable.

n_jobs [int, default=None] number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

verbose [bool, default=False] If verbose is True, the objective function and duality gap are printed at each iteration.

assume_centered [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_ [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [ndarray of shape (n_features, n_features)] Estimated covariance matrix.

precision_ [ndarray of shape (n_features, n_features)] Estimated precision matrix (inverse covariance).

alpha_ [float] Penalization parameter selected.

cv_alphas_ [list of shape (n_alphas,), dtype=float] All penalization parameters explored.

Deprecated since version 0.24: The cv_alphas_ attribute is deprecated in version 0.24 in favor of cv_results_['alphas'] and will be removed in version 0.26.

grid_scores_ [ndarray of shape (n_alphas, n_folds)] Log-likelihood score on left-out data across folds.
Deprecated since version 0.24: The grid_scores_ attribute is deprecated in version 0.24 in favor of cv_results_ and will be removed in version 0.26.

**cv_results_** [dict of ndarrays] A dict with keys:

- **alphas** [ndarray of shape (n_alphas,)] All penalization parameters explored.
- **split(k)_score** [ndarray of shape (n_alphas,)] Log-likelihood score on left-out data across (k)th fold.
- **mean_score** [ndarray of shape (n_alphas,)] Mean of scores over the folds.
- **std_score** [ndarray of shape (n_alphas,)] Standard deviation of scores over the folds.

New in version 0.24.

**n_iter_** [int] Number of iterations run for the optimal alpha.

See also:

```
graphical_lasso, GraphicalLasso
```

**Notes**

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLassoCV
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                      [0.0, 0.4, 0.0, 0.0],
...                      [0.2, 0.0, 0.3, 0.1],
...                      [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                     cov=true_cov,
...                                     size=200)
>>> cov = GraphicalLassoCV().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.051, 0.22 , 0.017],
       [0.051, 0.364, 0.018, 0.036],
       [0.22 , 0.018, 0.322, 0.094],
       [0.017, 0.036, 0.094, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```

**error_norm** *(comp_cov[, norm, scaling, squared])*

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** [“frobenius”, “spectral”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \( \sqrt{tr(A^t.A)} \) - ‘spectral’: \( \sqrt{\text{max(eigenvalues}(A^t.A))} \) where \( A \) is the error (comp_cov - self.covariance_).
- **scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

- **result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

**fit**(X, y=None)

Fits the GraphicalLasso covariance model to X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate
- **y** [Ignored] Not used, present for API consistence purpose.

**Returns**

- **self** [object]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Dictionary of parameters.
params [dict] Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis(X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score(X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [Ignored] Not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using sklearn.covariance.GraphicalLassoCV

- Sparse inverse covariance estimation
- Visualizing the stock market structure

7.5.5 sklearn.covariance.LedoitWolf

class sklearn.covariance.LedoitWolf(**kwargs)

LedoitWolf Estimator

Read more in the User Guide.

Parameters

- store_precision [bool, default=True] Specify if the estimated precision is stored.
- assume_centered [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.
- block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

Attributes

- covariance_ [ndarray of shape (n_features, n_features)] Estimated covariance matrix.
- location_ [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
- precision_ [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
- shrinkage_ [float] Coefficient in the convex combination used for the computation of the shrunk estimate. Range is [0, 1].

Notes

The regularised covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n_features)}\]

where \(\mu = \text{trace(cov)} / \text{n_features}\) and shrinkage is given by the Ledoit and Wolf formula (see References)
References

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import LedoitWolf
>>> real_cov = np.array([[.4, .2],
...                        [.2, .8]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0],
...                                    cov=real_cov,
...                                    size=50)
>>> cov = LedoitWolf().fit(X)
>>> cov.covariance_
array([[0.4406..., 0.1616...],
       [0.1616..., 0.8022...]])
>>> cov.location_
array([ 0.0595..., -0.0075...])
```

Methods

- `error_norm` (comp_cov[, norm, scaling, squared]) Computes the Mean Squared Error between two covariance estimators.
- `fit` (X[, y]) Fit the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.
- `get_params` ([deep]) Get parameters for this estimator.
- `get_precision`() Getter for the precision matrix.
- `mahalanobis` (X) Computes the squared Mahalanobis distances of given observations.
- `score` (X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.
- `set_params` (**params) Set the parameters of this estimator.

`error_norm` (comp_cov, norm=’frobenius’, scaling=True, squared=True) Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

- `comp_cov` [array-like of shape (n_features, n_features)] The covariance to compare with.
- `norm` [“frobenius”, “spectral”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).
- `scaling` [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- `squared` [bool, default=True] Whether to compute the squared error norm or the error norm.
If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fit the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored] not used, present for API consistence purpose.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [Ignored] Not used, present for API consistence purpose.
Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.covariance.LedoitWolf

- Ledoit-Wolf vs OAS estimation
- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)

7.5.6 sklearn.covariance.MinCovDet

class sklearn.covariance.MinCovDet (**kwargs)

Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a MinCovDet object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.

Read more in the User Guide.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction [float, default=None] The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of support_fraction will be used within the algorithm: (n_sample + n_features + 1) / 2. The parameter must be in the range (0, 1).

random_state [int, RandomState instance or None, default=None] Determines the pseudo random number generator for shuffling the data. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

Attributes
raw_location_ [ndarray of shape (n_features,)] The raw robust estimated location before correction and re-weighting.

raw_covariance_ [ndarray of shape (n_features, n_features)] The raw robust estimated covariance before correction and re-weighting.

raw_support_ [ndarray of shape (n_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

location_ [ndarray of shape (n_features,)] Estimated robust location.

covariance_ [ndarray of shape (n_features, n_features)] Estimated robust covariance matrix.

precision_ [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_ [ndarray of shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

dist_ [ndarray of shape (n_samples,)] Mahalanobis distances of the training set (on which fit is called) observations.

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import MinCovDet
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([[.8, .3],
...                       [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                              cov=real_cov,
...                              size=500)
>>> cov = MinCovDet(random_state=0).fit(X)

>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])

>>> cov.location_
array([0.0813..., 0.0427...])
```

**correct_covariance**(data)

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

**Parameters**

- **data** [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **covariance_corrected** [ndarray of shape (n_features, n_features)] Corrected robust covariance estimate.

**References**

[RVD]

**error_norm**(comp_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** ["frobenius", "spectral"]; default="frobenius"] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A'^t.A)) - 'spectral': sqrt(max(eigenvalues(A'^t.A)) where A is the error (comp_cov - self.covariance_).
- **scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

- **result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.

**fit**(X, y=None)

Fits a Minimum Covariance Determinant with the FastMCD algorithm.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where `n_samples` is the number of samples and `n_features` is the number of features.
y: Ignored  Not used, present for API consistence purpose.

Returns

self  [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

generate_samples (n_samples=1, random_state=None)
Generate random samples from the fitted Mahalanobis model.

Parameters

n_samples  [int, default=1] The number of random samples to generate.
random_state  [int, RandomState instance or None, default=None] Determines random number generation for
sampling from the fitted Mahalanobis model. Pass an int for determinis-

Returns

X  [ndarray of shape (n_samples, n_features)] Random samples generated from the fitted Mahalanobis model.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.

Returns

precision_  [array-like of shape (n_features, n_features)] The precision matrix associated to
the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X  [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances
of the which we compute. Observations are assumed to be drawn from the same distribu-
tion than the data used in fit.

Returns

dist  [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

reweight_covariance (data)
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the
data set before computing location and covariance estimates) described in [RVDriessen].

Parameters

data  [array-like of shape (n_samples, n_features)] The data matrix, with p features and n
samples. The data set must be the one which was used to compute the raw estimates.

Returns

location_reweighted  [ndarray of shape (n_features,)] Re-weighted robust location estimate.
covariance_reweighted  [ndarray of shape (n_features, n_features)] Re-weighted robust co-
variance estimate.
support_reweighted  [ndarray of shape (n_samples,), dtype=bool] A mask of the observa-
tions that have been used to compute the re-weighted robust location and covariance esti-
mates.
References

[RVDriessen]

score$(X_{\text{test}}, y=None)$
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

$X_{\text{test}}$ [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. $X_{\text{test}}$ is assumed to be drawn from the same distribution than the data used in fit (including centering).

$y$ [Ignored] Not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.covariance.MinCovDet

- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate

7.5.7 sklearn.covariance.OAS

class sklearn.covariance.OAS(**kwargs)
Oracle Approximating Shrinkage Estimator

Read more in the User Guide.

The formula used here does not correspond to the one given in the article. In the original article, formula (23) states that $2/p$ is multiplied by Trace(cov*cov) in both the numerator and denominator, but this operation is omitted because for a large p, the value of $2/p$ is so small that it doesn’t affect the value of the estimator.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.
**assume_centered** [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

**Attributes**

- **covariance_** [ndarray of shape (n_features, n_features)] Estimated covariance matrix.
- **location_** [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
- **precision_** [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
- **shrinkage_** [float] coefficient in the convex combination used for the computation of the shrunk estimate. Range is [0, 1].

**Notes**

The regularised covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n_features)}\]

where \(\mu = \text{trace(cov)} / \text{n_features}\) and shrinkage is given by the OAS formula (see References)

**References**

**Examples**

```python
>>> import numpy as np
>>> from sklearn.covariance import OAS
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([[.8, .3],
                       [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
                             cov=real_cov,
                             size=500)
>>> oas = OAS().fit(X)
>>> oas.covariance_
array([[0.7533..., 0.2763...],
       [0.2763..., 0.3964...]])
>>> oas.precision_
array([[ 1.7833..., -1.2431...],
       [-1.2431..., 3.3889...]])
>>> oas.shrinkage
0.0195...
```

**error_norm** *(comp_cov[, norm, scaling, squared])*

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** ["frobenius", “spectral”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).
- **scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

- **result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.

**fit** *(X, y=None)*

Fit the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored] not used, present for API consistence purpose.

**Returns**

- **self** [object]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool] If True, will also return parameters set via the initializers. If False, will return parameters set via `set_params`. If None, will return all parameters.

---

7.5. sklearn.covariance: Covariance Estimators 1723
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis(X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score(X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [Ignored] Not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.covariance.OAS`

- Normal, Ledoit-Wolf and OAS Linear Discriminant Analysis for classification
- Ledoit-Wolf vs OAS estimation
- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood

### 7.5.8 `sklearn.covariance.ShrunkCovariance`

```python
class sklearn.covariance.ShrunkCovariance(**kwargs)
```

Covariance estimator with shrinkage

Read more in the User Guide.

**Parameters**

- `store_precision` [bool, default=True] Specify if the estimated precision is stored
- `assume_centered` [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.
- `shrinkage` [float, default=0.1] Coefficient in the convex combination used for the computation of the shrink estimate. Range is [0, 1].

**Attributes**

- `covariance_` [ndarray of shape (n_features, n_features)] Estimated covariance matrix
- `location_` [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
- `precision_` [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

**Notes**

The regularized covariance is given by:

\[
(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \text{mu} \times \text{np.identity(n_features)}
\]

where \(\mu = \text{trace(cov)} / n\_\text{features}\)

**Examples**

```python
>>> import numpy as np
>>> from sklearn.covariance import ShrunckCovariance
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([[.8, .3],
                      [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
                             ...                           cov=real_cov,
                             ...                           size=500)
>>> cov = ShrunckCovariance().fit(X)
>>> cov.covariance_
array([[0.7387..., 0.2536...],
       [0.2536..., 0.4110...]])
```

(continues on next page)
Methods

- **error_norm**: Computes the Mean Squared Error between two covariance estimators.
- **fit**: Fit the shrunk covariance model according to the given training data and parameters.
- **get_params**: Get parameters for this estimator.
- **get_precision**: Getter for the precision matrix.
- **mahalanobis**: Computes the squared Mahalanobis distances of given observations.
- **score**: Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
- **set_params**: Set the parameters of this estimator.

**error_norm** *(comp_cov[, norm, scaling, squared])*  
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**
- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** [“frobenius”, “spectral”; default=”frobenius”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A))) where A is the error (comp_cov - self.covariance_).
- **scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**
- **result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.

**fit** *(X, y=None)*
Fit the shrunk covariance model according to the given training data and parameters.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y**: Ignored not used, present for API consistence purpose.

**Returns**
- **self** [object]
get_params (deep=True)
Get parameters for this estimator.

Parameters

deepl [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to
the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances
of the which we compute. Observations are assumed to be drawn from the same distribu-
tion than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its
covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the
likelihood, where n_samples is the number of samples and n_features is the number of
features. X_test is assumed to be drawn from the same distribution than the data used in
fit (including centering).

y [Ignored] Not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its
covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it's possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.covariance.shrunk_covariance`

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)

```python
covariance.empirical_covariance(X, *[, ...]) Computes the Maximum likelihood covariance estimator
covariance.graphical_lasso(emp_cov, alpha, *) penalized covariance estimator
covariance.ledoit_wolf(X, *[...]) Estimates the shrunk Ledoit-Wolf covariance matrix.
covariance.oas(X, *[..., assume_centered]) Estimate covariance with the Oracle Approximating Shrinkage algorithm.
covariance.shrunk_covariance(emp_cov,...) Calculates a covariance matrix shrunk on the diagonal
```

### 7.5.9 `sklearn.covariance.empirical_covariance`

`sklearn.covariance.empirical_covariance(X, *, assume_centered=False)`

Computes the Maximum likelihood covariance estimator

**Parameters**

- `X` [ndarray of shape (n_samples, n_features)] Data from which to compute the covariance estimate
- `assume_centered` [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

**Returns**

- `covariance` [ndarray of shape (n_features, n_features)] Empirical covariance (Maximum Likelihood Estimator).

**Examples**

```python
>>> from sklearn.covariance import empirical_covariance
>>> X = [[1, 1, 1], [1, 1, 1], [1, 1, 1], ...
    [0, 0, 0], [0, 0, 0], [0, 0, 0]]
>>> empirical_covariance(X)
array([[0.25, 0.25, 0.25],
       [0.25, 0.25, 0.25],
       [0.25, 0.25, 0.25]])
```
Examples using `sklearn.covariance.empirical_covariance`

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood

### 7.5.10 `sklearn.covariance.graphical_lasso`

`sklearn.covariance.graphical_lasso` is an 11-penalized covariance estimator.

**Parameters**

- `emp_cov` [ndarray of shape (n_features, n_features)] Empirical covariance from which to compute the covariance estimate.

- `alpha` [float] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance. Range is (0, inf).

- `cov_init` [array of shape (n_features, n_features), default=None] The initial guess for the covariance. If None, then the empirical covariance is used.

- `mode` [{'cd', 'lars'}, default='cd'] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

- `tol` [float, default=1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped. Range is (0, inf).

- `enet_tol` [float, default=1e-4] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'. Range is (0, inf).

- `max_iter` [int, default=100] The maximum number of iterations.

- `verbose` [bool, default=False] If verbose is True, the objective function and dual gap are printed at each iteration.

- `return_costs` [bool, default=False] If return_costs is True, the objective function and dual gap at each iteration are returned.

- `eps` [float, default=eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Default is `np.finfo(np.float64).eps`.

**Returns**

- `covariance` [ndarray of shape (n_features, n_features)] The estimated covariance matrix.

- `precision` [ndarray of shape (n_features, n_features)] The estimated (sparse) precision matrix.

- `costs` [list of (objective, dual_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if return_costs is True.

- `n_iter` [int] Number of iterations. Returned only if return_n_iter is set to True.

---

**7.5. `sklearn.covariance`: Covariance Estimators**
See also:

*GraphicalLasso*, *GraphicalLassoCV*

**Notes**

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R glasso package.

One possible difference with the glasso R package is that the diagonal coefficients are not penalized.

### 7.5.11 sklearn.covariance.ledoit_wolf

*sklearn.covariance.ledoit_wolf*(X, *, assume_centered=False, block_size=1000)

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate
- **assume_centered** [bool, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.
- **block_size** [int, default=1000] Size of the blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

**Returns**

- **shrunk_cov** [ndarray of shape (n_features, n_features)] Shrunk covariance.
- **shrinkage** [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

**Notes**

The regularized (shrunk) covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n_features)}\]

where \(\mu = \text{trace(cov)} / \text{n_features}\)

**Examples using sklearn.covariance.ledoit_wolf**

- *Sparse inverse covariance estimation*
7.5.12 sklearn.covariance.oas

sklearn.covariance.oas(X, *, assume_centered=False)

Estimate covariance with the Oracle Approximating Shrinkage algorithm.

Parameters

X [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate.

assume_centered [bool, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

Returns

shrunk_cov [array-like of shape (n_features, n_features)] Shrunk covariance.

shrinkage [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised (shrunk) covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

The formula we used to implement the OAS is slightly modified compared to the one given in the article. See OAS for more details.

7.5.13 sklearn.covariance.shrunk_covariance

sklearn.covariance.shrunk_covariance(emp_cov, shrinkage=0.1)

Calculates a covariance matrix shrunk on the diagonal.

Read more in the User Guide.

Parameters

emp_cov [array-like of shape (n_features, n_features)] Covariance matrix to be shrunk

shrinkage [float, default=0.1] Coefficient in the convex combination used for the computation of the shrunk estimate. Range is [0, 1].

Returns

shrunk_cov [ndarray of shape (n_features, n_features)] Shrunk covariance.
Notes

The regularized (shrunk) covariance is given by:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{id}(n_{\text{features}})\]

where \(\mu = \text{trace}(%\text{cov}) / n_{\text{features}}\)

7.6 sklearn.cross_decomposition: Cross decomposition

User guide: See the Cross decomposition section for further details.

<table>
<thead>
<tr>
<th>sklearn.cross_decomposition.CCA(**kwargs)</th>
<th>Canonical Correlation Analysis, also known as “Mode B” PLS.</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>sklearn.cross_decomposition.PLSSVD(**kwargs)</td>
<td>Partial Least Square SVD.</td>
</tr>
</tbody>
</table>

7.6.1 sklearn.cross_decomposition.CCA

class sklearn.cross_decomposition.CCA(**kwargs)

Canonical Correlation Analysis, also known as “Mode B” PLS.

Read more in the User Guide.

Parameters

- **n_components** [int, default=2] Number of components to keep. Should be in \([1, \min(n_{\text{samples}}, n_{\text{features}}, n_{\text{targets}})]\).
- **scale** [bool, default=True] Whether to scale \(X\) and \(Y\).
- **algorithm** [{'nipals', 'svd'}, default='nipals'] The algorithm used to estimate the first singular vectors of the cross-covariance matrix. ‘nipals’ uses the power method while ‘svd’ will compute the whole SVD.
- **max_iter** [int, default=500] the maximum number of iterations of the power method when algorithm='nipals'. Ignored otherwise.
- **tol** [real, default 1e-06] The tolerance used as convergence criteria in the power method: the algorithm stops whenever the squared norm of \(u_i - u_{(i-1)}\) is less than \(\text{tol}\), where \(u\) corresponds to the left singular vector.
- **copy** [bool, default=True] Whether to copy \(X\) and \(Y\) in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

- **x_weights_** [ndarray of shape (n_features, n_components)] The left singular vectors of the cross-covariance matrices of each iteration.
- **y_weights_** [ndarray of shape (n_targets, n_components)] The right singular vectors of the cross-covariance matrices of each iteration.
- **x_loadings_** [ndarray of shape (n_features, n_components)] The loadings of \(X\).
y_loadings_ [ndarray of shape (n_targets, n_components)] The loadings of $Y$.
x_scores_ [ndarray of shape (n_samples, n_components)] The transformed training samples.

Deprecation since version 0.24: x_scores_ is deprecated in 0.24 and will be removed in 0.26. You can just call transform on the training data instead.

y_scores_ [ndarray of shape (n_samples, n_components)] The transformed training targets.

Deprecation since version 0.24: y_scores_ is deprecated in 0.24 and will be removed in 0.26. You can just call transform on the training data instead.

x_rotations_ [ndarray of shape (n_features, n_components)] The projection matrix used to transform $X$.
y_rotations_ [ndarray of shape (n_features, n_components)] The projection matrix used to transform $Y$.

ccoef_ [ndarray of shape (n_features, n_targets)] The coefficients of the linear model such that $Y$ is approximated as $Y = X \circ coef_$. 

n_iter_ [list of shape (n_components,)] Number of iterations of the power method, for each component. Empty if algorithm='svd'.

</tr>
<tr>
<td>transform(X[, Y, copy])</td>
<td>Apply the dimension reduction.</td>
</tr>
</tbody>
</table>

```python
>>> fit(X, Y)
Path model to data.
```

Parameters
X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, ) or (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**fit_transform** (X, y=None)
Learn and apply the dimension reduction on the train data.

**Parameters**

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets), default=None] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**Returns**

x_scores if Y is not given, (x_scores, y_scores) otherwise.

**get_params** (deep=True)
Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**inverse_transform** (X)
Transform data back to its original space.

**Parameters**

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

**Returns**

x_reconstructed [array-like of shape (n_samples, n_features)]

**Notes**

This transformation will only be exact if n_components=n_features.

**predict** (X, copy=True)
Predict targets of given samples.

**Parameters**

X [array-like of shape (n_samples, n_features)] Samples.

copy [bool, default=True] Whether to copy X and y, or perform in-place normalization.
Notes

This call requires the estimation of a matrix of shape \((n\_features, n\_targets)\), which may be an issue in high dimensional space.

**score** \((X, y, sample\_weight=None)\)

Return the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \(1 - \frac{\sum (y_true - y_pred)^2}{\sum (y_true - y_true.mean())^2}\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

**Parameters**

- \(X\) [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- \(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for \(X\).
- \(sample\_weight\) [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- \(score\) [float] \(R^2\) of self.predict \((X)\) wrt. \(y\).

Notes

The \(R^2\) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of \(r2\_score\). This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<component>\_<parameter>\) so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- \(self\) [estimator instance] Estimator instance.

**transform** \((X, Y=None, copy=True)\)

Apply the dimension reduction.

**Parameters**

- \(X\) [array-like of shape (n_samples, n_features)] Samples to transform.
- \(Y\) [array-like of shape (n_samples, n_targets), default=None] Target vectors.
- \(copy\) [bool, default=True] Whether to copy \(X\) and \(Y\), or perform in-place normalization.

**Returns**

- \(x\_scores\) if \(Y\) is not given, \((x\_scores, y\_scores)\) otherwise.
Examples using `sklearn.cross_decomposition.CCA`

- Compare cross decomposition methods
- Multilabel classification

### 7.6.2 sklearn.cross_decomposition.PLSCanonical

```python
class sklearn.cross_decomposition.PLSCanonical(**kwargs)
```

Partial Least Squares transformer and regressor.

Read more in the User Guide.

New in version 0.8.

**Parameters**

- `n_components` [int, default=2] Number of components to keep. Should be in \([1, \min(n_{samples}, n_{features}, n_{targets})]\).
- `scale` [bool, default=True] Whether to scale \(X\) and \(Y\).
- `algorithm` [{'nipals', 'svd'}, default='nipals'] The algorithm used to estimate the first singular vectors of the cross-covariance matrix. 'nipals' uses the power method while 'svd' will compute the whole SVD.
- `max_iter` [int, default=500] the maximum number of iterations of the power method when `algorithm='nipals'`. Ignored otherwise.
- `tol` [real, default 1e-06] The tolerance used as convergence criteria in the power method: the algorithm stops whenever the squared norm of \(u_i - u_(i-1)\) is less than `tol`, where \(u\) corresponds to the left singular vector.
- `copy` [bool, default=True] Whether to copy \(X\) and \(Y\) in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

**Attributes**

- `x_weights_` [ndarray of shape (n_features, n_components)] The left singular vectors of the cross-covariance matrices of each iteration.
- `y_weights_` [ndarray of shape (n_targets, n_components)] The right singular vectors of the cross-covariance matrices of each iteration.
- `x_loadings_` [ndarray of shape (n_features, n_components)] The loadings of \(X\).
- `y_loadings_` [ndarray of shape (n_targets, n_components)] The loadings of \(Y\).
- `x_scores_` [ndarray of shape (n_samples, n_components)] The transformed training samples.
  
  Deprecated since version 0.24: `x_scores_` is deprecated in 0.24 and will be removed in 0.26. You can just call transform on the training data instead.
- `y_scores_` [ndarray of shape (n_samples, n_components)] The transformed training targets.
  
  Deprecated since version 0.24: `y_scores_` is deprecated in 0.24 and will be removed in 0.26. You can just call transform on the training data instead.
- `x_rotations_` [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(X\).
- `y_rotations_` [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(Y\).
coef_ [ndarray of shape (n_features, n_targets)] The coefficients of the linear model such that $Y$

is approximated as $Y = X @ coef_.$

n_iter_ [list of shape (n_components,)] Number of iterations of the power method, for each

cOMPONENT. Empty if algorithm='svd'.

CCA

PLSSVD

Examples

```python
>>> from sklearn.cross_decomposition import PLSCanonical
>>> X = [[0. , 0. , 1. ], [1. , 0. , 0. ], [2. , 2. , 2. ], [2. , 5. , 4. ]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> plsca = PLSCanonical(n_components=2)
>>> plsca.fit(X, Y)
PLSCanonical()
>>> X_c, Y_c = plsca.transform(X, Y)
```

Methods

```python
fit(X, Y) Fit model to data.
fit_transform(X[, y]) Learn and apply the dimension reduction on the train

data.
get_params([deep]) Get parameters for this estimator.
inverse_transform(X) Transform data back to its original space.
predict(X[, copy]) Predict targets of given samples.
.score(X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the pre-
diction.
set_params(**params) Set the parameters of this estimator.
transform(X[, Y , copy]) Apply the dimension reduction.
```

fit (X, Y)

Fit model to data.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.</td>
</tr>
<tr>
<td>Y</td>
<td>array-like of shape (n_samples, ) or (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.</td>
</tr>
</tbody>
</table>

fit_transform (X, y=None)

Learn and apply the dimension reduction on the train data.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.</td>
</tr>
</tbody>
</table>
y [array-like of shape (n_samples, n_targets), default=None] Target vectors, where
n_samples is the number of samples and n_targets is the number of response variables.

Returns

  x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

  params [dict] Parameter names mapped to their values.

inverse_transform (X)
Transform data back to its original space.

Parameters

  X [array-like of shape (n_samples, n_components)] New data, where n_samples is the
  number of samples and n_components is the number of pls components.

Returns

  x_reconstructed [array-like of shape (n_samples, n_features)]

Notes

  This transformation will only be exact if n_components=n_features.

predict (X, copy=True)
Predict targets of given samples.

Parameters

  X [array-like of shape (n_samples, n_features)] Samples.
  copy [bool, default=True] Whether to copy X and y, or perform in-place normalization.

Notes

  This call requires the estimation of a matrix of shape (n_features, n_targets), which may be an
  issue in high dimensional space.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})
** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X, Y=None, copy=True)

Apply the dimension reduction.

Parameters

X [array-like of shape (n_samples, n_features)] Samples to transform.

Y [array-like of shape (n_samples, n_targets), default=None] Target vectors.

copy [bool, default=True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using sklearn.cross_decomposition.PLSCanonical

- Compare cross decomposition methods
PLS regression

PLSRegression is also known as PLS2 or PLS1, depending on the number of targets.

Read more in the User Guide.

New in version 0.8.

Parameters

- **n_components** [int, default=2] Number of components to keep. Should be in \([1, \min(n_{\text{samples}}, n_{\text{features}}, n_{\text{targets}})]\).
- **scale** [bool, default=True] Whether to scale \(X\) and \(Y\).
- **algorithm** [\{‘nipals’, ‘svd’\}, default=’nipals’] The algorithm used to estimate the first singular vectors of the cross-covariance matrix. ‘nipals’ uses the power method while ‘svd’ will compute the whole SVD.
- **max_iter** [int, default=500] The maximum number of iterations of the power method when algorithm='nipals'. Ignored otherwise.
- **tol** [real, default 1e-06] The tolerance used as convergence criteria in the power method: the algorithm stops whenever the squared norm of \(u_i - u_{i-1}\) is less than \(\text{tol}\), where \(u\) corresponds to the left singular vector.
- **copy** [bool, default=True] Whether to copy \(X\) and \(Y\) in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

- **x_weights_** [ndarray of shape (n_features, n_components)] The left singular vectors of the cross-covariance matrices of each iteration.
- **y_weights_** [ndarray of shape (n_targets, n_components)] The right singular vectors of the cross-covariance matrices of each iteration.
- **x_loadings_** [ndarray of shape (n_features, n_components)] The loadings of \(X\).
- **y_loadings_** [ndarray of shape (n_targets, n_components)] The loadings of \(Y\).
- **x_scores_** [ndarray of shape (n_samples, n_components)] The transformed training samples.
- **y_scores_** [ndarray of shape (n_samples, n_components)] The transformed training targets.
- **x_rotations_** [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(X\).
- **y_rotations_** [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(Y\).
- **coef_** [ndarray of shape (n_features, n_targets)] The coefficients of the linear model such that \(Y\) is approximated as \(Y = X @ \text{coef}_\).
- **n_iter_** [list of shape (n_components,)] Number of iterations of the power method, for each component. Empty if algorithm='svd'.

---

**fit (X, Y)**

Fit model to data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

- **Y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**fit_transform (X, y= None)**

Learn and apply the dimension reduction on the train data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

- **y** [array-like of shape (n_samples, n_targets), default=None] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**Returns**

- **x_scores** if Y is not given, (**x_scores, y_scores**) otherwise.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**inverse_transform** *(X)*

Transform data back to its original space.

**Parameters**

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

**Returns**

x_reconstructed [array-like of shape (n_samples, n_features)]

**Notes**

This transformation will only be exact if n_components=n_features.

**predict** *(X, copy=True)*

Predict targets of given samples.

**Parameters**

X [array-like of shape (n_samples, n_features)] Samples.

copy [bool, default=True] Whether to copy X and y, or perform in-place normalization.

**Notes**

This call requires the estimation of a matrix of shape (n_features, n_targets), which may be an issue in high dimensional space.

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (X, Y=None, copy=True)

Apply the dimension reduction.

**Parameters**

X [array-like of shape (n_samples, n_features)] Samples to transform.

Y [array-like of shape (n_samples, n_targets), default=None] Target vectors.

copy [bool, default=True] Whether to copy X and Y, or perform in-place normalization.

**Returns**

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using `sklearn.cross_decomposition.PLSRegression`

- Principal Component Regression vs Partial Least Squares Regression
- Compare cross decomposition methods

7.6.4 `sklearn.cross_decomposition.PLSSVD`

class `sklearn.cross_decomposition.PLSSVD(**kwargs)`

Partial Least Square SVD.

This transformer simply performs a SVD on the crosscovariance matrix $X'Y$. It is able to project both the training data $X$ and the targets $Y$. The training data $X$ is projected on the left singular vectors, while the targets are projected on the right singular vectors.

Read more in the `User Guide`.

New in version 0.8.

**Parameters**

n_components [int, default=2] The number of components to keep. Should be in $[1, \min(n_{samples}, n_{features}, n_{targets})]$. 

scale [bool, default=True] Whether to scale $X$ and $Y$. 

---

7.6. `sklearn.cross_decomposition`: Cross decomposition 1743
copy [bool, default=True] Whether to copy X and Y in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

x_weights_ [ndarray of shape (n_features, n_components)] The left singular vectors of the SVD of the cross-covariance matrix. Used to project X in transform.

y_weights_ [ndarray of (n_targets, n_components)] The right singular vectors of the SVD of the cross-covariance matrix. Used to project X in transform.

x_scores_ [ndarray of shape (n_samples, n_components)] The transformed training samples.

Deprecated since version 0.24: x_scores_ is deprecated in 0.24 and will be removed in 0.26. You can just call transform on the training data instead.

y_scores_ [ndarray of shape (n_samples, n_components)] The transformed training targets.

Deprecated since version 0.24: y_scores_ is deprecated in 0.24 and will be removed in 0.26. You can just call transform on the training data instead.

Examples

```python
>>> import numpy as np
>>> from sklearn.cross_decomposition import PLSSVD
>>> X = np.array([[0., 0., 1.],
...               [1., 0., 0.],
...               [2., 2., 2.],
...               [2., 5., 4.]])
>>> Y = np.array([[0.1, -0.2],
...               [0.9, 1.1],
...               [6.2, 5.9],
...               [11.9, 12.3]])
>>> pls = PLSSVD(n_components=2).fit(X, Y)
>>> X_c, Y_c = pls.transform(X, Y)
>>> X_c.shape, Y_c.shape
((4, 2), (4, 2))
```

Methods

`fit(X, Y)`

Fit model to data.

Parameters
X [array-like of shape (n_samples, n_features)] Training samples.
Y [array-like of shape (n_samples,) or (n_samples, n_targets)] Targets.

**fit_transform**(X, y=None)
Learn and apply the dimensionality reduction.

Parameters
X [array-like of shape (n_samples, n_features)] Training samples.
y [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Targets.

Returns
out [array-like or tuple of array-like] The transformed data X_transformed if Y is not None, (X_transformed, Y_transformed) otherwise.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

**set_params**(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

**transform**(X, Y=None)
Apply the dimensionality reduction.

Parameters
X [array-like of shape (n_samples, n_features)] Samples to be transformed.
Y [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Targets.

Returns
out [array-like or tuple of array-like] The transformed data X_transformed if Y is not None, (X_transformed, Y_transformed) otherwise.
## 7.7 sklearn.datasets: Datasets

The `sklearn.datasets` module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

**User guide:** See the Dataset loading utilities section for further details.

### 7.7.1 Loaders

<table>

<td>Load and return the wine dataset (classification).</td>
</tr>
</tbody>
</table>
**sklearn.datasets.clear_data_home**

Delete all the content of the data home cache.

**Parameters**

- **data_home** [str | None] The path to scikit-learn data dir.

**sklearn.datasets.dump_svmlight_file**

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [{array-like, sparse matrix}, shape = [n_samples, n_labels]] Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.
- **f** [string or file-like in binary mode] If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.
- **zero_based** [boolean, default=True] Whether column indices should be written zero-based (True) or one-based (False).
- **comment** [string, default=None] Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.
- **query_id** [array-like of shape (n_samples,), default=None] Array containing pairwise preference constraints (qid in svmlight format).
- **multilabel** [boolean, default=False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

New in version 0.17: parameter multilabel to support multilabel datasets.

**Examples using sklearn.datasets.dump_svmlight_file**

- **Libsvm GUI**
sklearn.datasets.fetch_20newsgroups

Load the filenames and data from the 20 newsgroups dataset (classification).
Download it if necessary.

Parameters

- **data_home** [str, default=None] Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
- **subset** [{'train', 'test', 'all'}, default='train'] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.
- **categories** [array-like, dtype=str or unicode, default=None] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).
- **shuffle** [bool, default=True] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.
- **remove** [tuple, default=()] May contain any subset of (‘headers’, ‘footers’, ‘quotes’). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.
  - ‘headers’ removes newsgroup headers, ‘footers’ removes blocks at the ends of posts that look like signatures, and ‘quotes’ removes lines that appear to be quoting another post.
  - ‘headers’ follows an exact standard; the other filters are not always correct.
- **download_if_missing** [bool, default=True] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.
- **return_X_y** [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.

Returns

- **bunch** [Bunch] Dictionary-like object, with the following attributes.
  - **data** [list of shape (n_samples,)] The data list to learn.
  - **target**: ndarray of shape (n_samples,) The target labels.
  - **filenames**: list of shape (n_samples,) The path to the location of the data.
  - **DESCR**: str The full description of the dataset.
**target_names**: list of shape (n_classes,) The names of target classes.

**(data, target)** [tuple if return_X_y=True] New in version 0.22.

**Examples using sklearn.datasets.fetch_20newsgroups**

- Sample pipeline for text feature extraction and evaluation

```
from sklearn.datasets import fetch_20newsgroups_vectorized

fetch_20newsgroups_vectorized(*, subset='train', remove=(), data_home=None, download_if_missing=True, return_X_y=False, normalize=True)
```

Load the 20 newsgroups dataset and vectorize it into token counts (classification).

Download it if necessary.

This is a convenience function; the transformation is done using the default settings for CountVectorizer. For more advanced usage (stopword filtering, n-gram extraction, etc.), combine fetch_20newsgroups with a custom CountVectorizer, HashingVectorizer, TfidfTransformer or TfidfVectorizer.

The resulting counts are normalized using sklearn.preprocessing.normalize unless normalize is set to False.

```
<table>
<thead>
<tr>
<th>Classes</th>
<th>20</th>

</tr>
</tbody>
</table>
```

Read more in the User Guide.

**Parameters**

- **subset** [{‘train’, ‘test’, ‘all’}, default=’train’] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.

- **remove** [tuple, default=()]] May contain any subset of (‘headers’, ‘footers’, ‘quotes’). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

  - ‘headers’ removes newsgroup headers,
  - ‘footers’ removes blocks at the ends of posts that look like signatures,
  - ‘quotes’ removes lines that appear to be quoting another post.

- **data_home** [str, default=None] Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **download_if_missing** [bool, default=True] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

- **return_X_y** [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.

  New in version 0.20.

- **normalize** [bool, default=True] If True, normalizes each document’s feature vector to unit norm using sklearn.preprocessing.normalize.

  New in version 0.22.
Returns

bunch [Bunch] Dictionary-like object, with the following attributes.

data: sparse matrix of shape (n_samples, n_features) The data matrix to learn.
target: ndarray of shape (n_samples,) The target labels.
target_names: list of shape (n_classes,) The names of target classes.
DESCR: str The full description of the dataset.
(data, target) [tuple if return_X_y is True] New in version 0.20.

Examples using sklearn.datasets.fetch_20newsgroups_vectorized

- Model Complexity Influence
- Multiclass sparse logistic regression on 20newsgroups
- The Johnson-Lindenstrauss bound for embedding with random projections

sklearn.datasets.fetch_california_housing

sklearn.datasets.fetch_california_housing(*, data_home=None, download_if_missing=True, return_X_y=False, as_frame=False)

Load the California housing dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>20640</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>8</td>
</tr>
<tr>
<td>Features</td>
<td>real</td>
</tr>
<tr>
<td>Target</td>
<td>real 0.15 - 5.</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

data_home [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.20.

as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target_columns.

New in version 0.23.

Returns

dataset [Bunch] Dictionary-like object, with the following attributes.

data [ndarray, shape (20640, 8)] Each row corresponding to the 8 feature values in order.

If as_frame is True, data is a pandas object.
target [numpy array of shape (20640,)] Each value corresponds to the average house value in units of 100,000. If as_frame is True, target is a pandas object.

feature_names [list of length 8] Array of ordered feature names used in the dataset.

DESCR [string] Description of the California housing dataset.

frame [pandas DataFrame] Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

(data, target) [tuple if return_X_y is True] New in version 0.20.

Notes

This dataset consists of 20,640 samples and 9 features.

Examples using sklearn.datasets.fetch_california_housing

• Partial Dependence and Individual Conditional Expectation Plots
• Imputing missing values with variants of IterativeImputer
• Imputing missing values before building an estimator
• Compare the effect of different scalers on data with outliers

sklearn.datasets.fetch_covtype

sklearn.datasets.fetch_covtype(*, data_home=None, download_if_missing=True, random_state=None, shuffle=False, return_X_y=False, as_frame=False)

Load the covtype dataset (classification).

Download it if necessary.

<table>
<thead>
<tr>

<tr>
<td>Dimensionality</td>
<td>54</td>
</tr>
<tr>
<td>Features</td>
<td>int</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

data_home [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

shuffle [bool, default=False] Whether to shuffle dataset.
return_X_y [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.20.

as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.

New in version 0.24.

Returns
dataset [Bunch] Dictionary-like object, with the following attributes.
data [ndarray of shape (581012, 54)] Each row corresponds to the 54 features in the dataset.
target [ndarray of shape (581012,)] Each value corresponds to one of the 7 forest cover-types with values ranging between 1 to 7.
frame [dataframe of shape (581012, 53)] Only present when as_frame=True. Contains data and target.
DESCR [str] Description of the forest covertype dataset.
feature_names [list] The names of the dataset columns.
target_names: list The names of the target columns.
(data, target) [tuple if return_X_y is True] New in version 0.20.

Examples using sklearn.datasets.fetch_covtype

Scalable learning with polynomial kernel aproximation

sklearn.datasets.fetch_kddcup99

Load the kddcup99 dataset (classification).

Download it if necessary.

Read more in the User Guide.

New in version 0.18.

Parameters

data_home [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders. .. versionadded:: 0.19

shuffle [bool, default=False] Whether to shuffle dataset.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling and for selection of abnormal samples if subset='SA'. Pass an int for reproducible output across multiple function calls. See Glossary.

percent10 [bool, default=True] Whether to load only 10 percent of the data.

download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object. New in version 0.20.

as_frame [bool, default=False] If True, returns a pandas DataFrame for the data and target objects in the Bunch returned object; Bunch return object will also have a frame member.

New in version 0.24.

Returns

data [Bunch] Dictionary-like object, with the following attributes.

data [{ndarray, dataframe} of shape (494021, 41)] The data matrix to learn. If as_frame=True, data will be a pandas DataFrame.

target [{ndarray, series} of shape (494021,)] The regression target for each sample. If as_frame=True, target will be a pandas Series.

frame [dataframe of shape (494021, 42)] Only present when as_frame=True. Contains data and target.

DESCR [str] The full description of the dataset.

feature_names [list] The names of the dataset columns

target_names: list The names of the target columns

(data, target) [tuple if return_X_y is True] New in version 0.20.

sklearn.datasets.fetch_lfw_pairs

sklearn.datasets.fetch_lfw_pairs(*, subset='train', data_home=None, funneled=True, resize=0.5, color=False, slice_=(slice(70, 195, None), slice(78, 172, None)), download_if_missing=True)

Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).

Download it if necessary.

<table>

</tr>
<tr>
<td>Features</td>
<td>real, between 0 and 255</td>
</tr>
</tbody>
</table>
In the official README.txt this task is described as the “Restricted” task. As I am not sure as to implement the “Unrestricted” variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47. Read more in the User Guide.

**Parameters**

- **subset** [{‘train’, ‘test’, ‘10_folds’}, default=’train’] Select the dataset to load: ‘train’ for the development training set, ‘test’ for the development test set, and ‘10_folds’ for the official evaluation set that is meant to be used with a 10-folds cross validation.

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **funneled** [bool, default=True] Download and use the funneled variant of the dataset.

- **resize** [float, default=0.5] Ratio used to resize the each face picture.

- **color** [bool, default=False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

- **slice_** [tuple of slice, default=(slice(70, 195), slice(78, 172))] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background.

- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**

- **data** [Bunch] Dictionary-like object, with the following attributes.
  - **data** [ndarray of shape (2200, 5828). Shape depends on subset.] Each row corresponds to 2 ravel’d face images of original size 62 x 47 pixels. Changing the slice_, resize or subset parameters will change the shape of the output.
  - **pairs** [ndarray of shape (2200, 2, 62, 47). Shape depends on subset.] Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the slice_, resize or subset parameters will change the shape of the output.
  - **target** [numpy array of shape (2200,)] Labels associated to each pair of images. The two label values being different persons or the same person.
  - **DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.

**Example**

```python
sklearn.datasets.fetch_lfw_people(*, data_home=None, funneled=True, resize=0.5, min_faces_per_person=0, color=False, slice_=slice(70, 195, None), slice_2=slice(78, 172, None), download_if_missing=True, return_X_y=False)
```

Load the Labeled Faces in the Wild (LFW) people dataset (classification). Download it if necessary.
Classes | 5749  
---|---
Samples total | 13233  
Dimensionality | 5828  
Features | real, between 0 and 255

Read more in the *User Guide*.

**Parameters**

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **funneled** [bool, default=True] Download and use the funneled variant of the dataset.

- **resize** [float, default=0.5] Ratio used to resize the each face picture.

- **min_faces_per_person** [int, default=None] The extracted dataset will only retain pictures of people that have at least `min_faces_per_person` different pictures.

- **color** [bool, default=False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

- **slice_** [tuple of slice, default=(slice(70, 195), slice(78, 172))] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background.

- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

- **return_X_y** [bool, default=False] If True, returns `(dataset.data, dataset.target)` instead of a Bunch object. See below for more information about the `dataset.data` and `dataset.target` object.

  New in version 0.20.

**Returns**

- **dataset** [*Bunch*] Dictionary-like object, with the following attributes.

  - **data** [numpay array of shape (13233, 2914)] Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the `slice_` or resize parameters will change the shape of the output.

  - **images** [numpay array of shape (13233, 62, 47)] Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the `slice_` or resize parameters will change the shape of the output.

  - **target** [numpay array of shape (13233,)] Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.

  - **DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.

  - **(data, target)** [tuple if `return_X_y` is True] New in version 0.20.
Examples using `sklearn.datasets.fetch_lfw_people`

- Faces recognition example using eigenfaces and SVMs

`sklearn.datasets.fetch_olivetti_faces`

`sklearn.datasets.fetch_olivetti_faces(*, data_home=None, shuffle=False, random_state=0, download_if_missing=True, return_X_y=False)`

Load the Olivetti faces data-set from AT&T (classification).

Download it if necessary.

Read more in the User Guide.

Parameters

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
- **shuffle** [bool, default=False] If True the order of the dataset is shuffled to avoid having images of the same person grouped.
- **random_state** [int, RandomState instance or None, default=0] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.
- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
- **return_X_y** [bool, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the data and target object.

New in version 0.22.

Returns

- **data** [Bunch] Dictionary-like object, with the following attributes.

  - **data**: ndarray, shape (400, 4096) Each row corresponds to a ravelled face image of original size 64 x 64 pixels.
  - **images**: [ndarray, shape (400, 64, 64)] Each row is a face image corresponding to one of the 40 subjects of the dataset.
  - **target**: [ndarray, shape (400,)] Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.
  - **DESCR** [str] Description of the modified Olivetti Faces Dataset.

  (data, target) [tuple if return_X_y=True] New in version 0.22.
Examples using sklearn.datasets.fetch_olivetti_faces

- Online learning of a dictionary of parts of faces
- Faces dataset decompositions
- Pixel importances with a parallel forest of trees
- Face completion with a multi-output estimators

sklearn.datasets.fetch_openml

Fetch dataset from openml by name or dataset id.

Datasets are uniquely identified by either an integer ID or by a combination of name and version (i.e. there might be multiple versions of the ‘iris’ dataset). Please give either name or data_id (not both). In case a name is given, a version can also be provided.

Read more in the User Guide.

New in version 0.20.

Note: EXPERIMENTAL

The API is experimental (particularly the return value structure), and might have small backward-incompatible changes without notice or warning in future releases.

Parameters

name [str, default=None] String identifier of the dataset. Note that OpenML can have multiple datasets with the same name.

version [int or ‘active’, default=’active’] Version of the dataset. Can only be provided if also name is given. If ‘active’ the oldest version that’s still active is used. Since there may be more than one active version of a dataset, and those versions may fundamentally be different from one another, setting an exact version is highly recommended.

data_id [int, default=None] OpenML ID of the dataset. The most specific way of retrieving a dataset. If data_id is not given, name (and potential version) are used to obtain a dataset.

data_home [str, default=None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

target_column [str, list or None, default=’default-target’] Specify the column name in the data to use as target. If ‘default-target’, the standard target column a stored on the server is used. If None, all columns are returned as data and the target is None. If list (of strings), all columns with these names are returned as multi-target (Note: not all scikit-learn classifiers can handle all types of multi-output combinations)

cache [bool, default=True] Whether to cache downloaded datasets using joblib.

return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target objects.
as_frame [bool or ‘auto’, default=’auto’] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target columns. The Bunch will contain a frame attribute with the target and the data. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as describe above.

If as_frame is ‘auto’, the data and target will be converted to DataFrame or Series as if as_frame is set to True, unless the dataset is stored in sparse format.

Changed in version 0.24: The default value of as_frame changed from False to ‘auto’ in 0.24.

Returns

data [Bunch] Dictionary-like object, with the following attributes.

  data [np.array, scipy.sparse.csr_matrix of floats, or pandas DataFrame] The feature matrix. Categorical features are encoded as ordinals.

  target [np.array, pandas Series or DataFrame] The regression target or classification labels, if applicable. Dtype is float if numeric, and object if categorical. If as_frame is True, target is a pandas object.

  DESCR [str] The full description of the dataset

  feature_names [list] The names of the dataset columns

  target_names: list The names of the target columns

New in version 0.22.

categories [dict or None] Maps each categorical feature name to a list of values, such that the value encoded as i is ith in the list. If as_frame is True, this is None.

details [dict] More metadata from OpenML

frame [pandas DataFrame] Only present when as_frame=True. DataFrame with data and target.

(data, target) [tuple if return_X_y is True]

Note: EXPERIMENTAL

This interface is experimental and subsequent releases may change attributes without notice (although there should only be minor changes to data and target).

Missing values in the ‘data’ are represented as NaN’s. Missing values in ‘target’ are represented as NaN’s (numerical target) or None (categorical target)

Examples using sklearn.datasets.fetch_openml

- Approximate nearest neighbors in TSNE
sklearn.datasets.fetch_rcv1

sklearn.datasets.fetch_rcv1(*, data_home=None, subset='all', download_if_missing=True, random_state=None, shuffle=False, return_X_y=False)

Load the RCV1 multilabel dataset (classification).

Download it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

</tr>
</tbody>
</table>

Read more in the User Guide.

New in version 0.17.

Parameters

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **subset** [‘train’, ‘test’, ‘all’], default=’all’ Select the dataset to load: ‘train’ for the training set (23149 samples), ‘test’ for the test set (781265 samples), ‘all’ for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

- **shuffle** [bool, default=False] Whether to shuffle dataset.

- **return_X_y** [bool, default=False] If True, returns (dataset.data, dataset.target) instead of a Bunch object. See below for more information about the dataset.data and dataset.target object.

New in version 0.20.

Returns

- **dataset** [Bunch] Dictionary-like object, with the following attributes.

  - **data** [sparse matrix of shape (804414, 47236), dtype=np.float64] The array has 0.16% of non zero values. Will be of CSR format.

  - **target** [sparse matrix of shape (804414, 103), dtype=np.uint8] Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values. Will be of CSR format.

  - **sample_id** [ndarray of shape (804414,), dtype=np.uint32] Identification number of each sample, as ordered in dataset.data.

  - **target_names** [ndarray of shape (103,), dtype=object] Names of each target (RCV1 topics), as ordered in dataset.target.

- **DESCR** [str] Description of the RCV1 dataset.

  (data, target) [tuple if return_X_y is True] New in version 0.20.
sklearn.datasets.fetch_species_distributions

sklearn.datasets.fetch_species_distributions(*, data_home=None, download_if_missing=True)

Loader for species distribution dataset from Phillips et. al. (2006)

Read more in the User Guide.

Parameters

data_home [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

data [Bunch] Dictionary-like object, with the following attributes.

coverages [array, shape = [14, 1592, 1212]] These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.

train [record array, shape = (1624,)] The training points for the data. Each point has three fields:
  • train[‘species’] is the species name
  • train[‘dd long’] is the longitude, in degrees
  • train[‘dd lat’] is the latitude, in degrees

test [record array, shape = (620,)] The test points for the data. Same format as the training data.

Nx, Ny [integers] The number of longitudes (x) and latitudes (y) in the grid

x_left_lower_corner, y_left_lower_corner [floats] The (x,y) position of the lower-left corner, in degrees

grid_size [float] The spacing between points of the grid, in degrees

Notes

This dataset represents the geographic distribution of species. The dataset is provided by Phillips et. al. (2006). The two species are:

• “Bradypus variegatus”, the Brown-throated Sloth.
• “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.
• For an example of using this dataset with scikit-learn, see examples/applications/plot_species_distribution_modeling.py.

- Species distribution modeling
- Kernel Density Estimate of Species Distributions

`sklearn.datasets.get_data_home`

`sklearn.datasets.get_data_home(data_home=None) → str`

Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named ‘scikit_learn_data’ in the user home folder.

Alternatively, it can be set by the ‘SCIKIT_LEARN_DATA’ environment variable or programmatically by giving an explicit folder path. The ‘~’ symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

**Parameters**

- `data_home` [str | None] The path to scikit-learn data dir.

Examples using `sklearn.datasets.get_data_home`

- Out-of-core classification of text documents

`sklearn.datasets.load_boston`

`sklearn.datasets.load_boston(*, return_X_y=False)`

Load and return the boston house-prices dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>

**Parameters**

- `return_X_y` [bool, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

  New in version 0.18.

**Returns**

- `data` [Bunch] Dictionary-like object, with the following attributes.
**data**  [ndarray of shape (506, 13)]  The data matrix.

**target**  [ndarray of shape (506, )]  The regression target.

**filename**  [str]  The physical location of boston csv dataset.

New in version 0.20.

**DESCR**  [str]  The full description of the dataset.

**feature_names**  [ndarray]  The names of features

(data, target)  [tuple if return_X_y is True]  New in version 0.18.

**Examples**

```python
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> print(X.shape)
(506, 13)
```

**Notes**

Changed in version 0.20: Fixed a wrong data point at [445, 0].

**sklearn.datasets.load_breast_cancer**

`sklearn.datasets.load_breast_cancer(*, return_X_y=False, as_frame=False)`

Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

**Parameters**

- **return_X_y**  [bool, default=False]  If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

- **as_frame**  [bool, default=False]  If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.

New in version 0.23.

**Returns**

- **data**  [Bunch]  Dictionary-like object, with the following attributes.
data  [[ndarray, dataframe] of shape (569, 30)] The data matrix. If as_frame=True, data will be a pandas DataFrame.

target:  [ndarray, Series] of shape (569,) The classification target. If as_frame=True, target will be a pandas Series.

feature_names: list  The names of the dataset columns.

target_names: list  The names of target classes.

frame:  DataFrame of shape (569, 31) Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

DESCR: str  The full description of the dataset.

filename: str  The path to the location of the data.

New in version 0.20.

(data, target)  [tuple if return_X_y is True] New in version 0.18.

The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is downloaded from:

https://goo.gl/U2Uwz2

Examples

Let’s say you are interested in the samples 10, 50, and 85, and want to know their class name.

```python
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

Examples using sklearn.datasets.load_breast_cancer

- Post pruning decision trees with cost complexity pruning
- Permutation Importance with Multicollinear or Correlated Features

sklearn.datasets.load_diabetes

sklearn.datasets.load_diabetes(*, return_X_y=False, as_frame=False)

Load and return the diabetes dataset (regression).

<table>
<thead>
<tr>

<td>integer 25 - 346</td>
</tr>
</tbody>
</table>

Read more in the User Guide.
Parameters

**return_X_y** [bool, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

**as_frame** [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If `return_X_y` is True, then `(data, target)` will be pandas DataFrames or Series as described below.

New in version 0.23.

Returns

**data** `[Bunch]` Dictionary-like object, with the following attributes.

- `data` `[[ndarray, dataframe] of shape (442, 10)]` The data matrix. If `as_frame=True`, `data` will be a pandas DataFrame.
- `target` `[[ndarray, Series] of shape (442,)]` The regression target. If `as_frame=True`, `target` will be a pandas Series.
- `feature_names`: list The names of the dataset columns.
- `frame`: `Dataframe of shape (442, 11)` Only present when `as_frame=True`. DataFrame with `data` and `target`.

New in version 0.23.

**DESCR**: str The full description of the dataset.

**data_filename**: str The path to the location of the data.

**target_filename**: str The path to the location of the target.

`(data, target)` `[tuple if `return_X_y` is True] New in version 0.18.

Examples using `sklearn.datasets.load_diabetes`

- Plot individual and voting regression predictions
- Gradient Boosting regression
- Model Complexity Influence
- Model-based and sequential feature selection
- Lasso path using LARS
- Linear Regression Example
- Sparsity Example: Fitting only features 1 and 2
- Lasso and Elastic Net
- Lasso model selection: Cross-Validation / AIC / BIC
- Advanced Plotting With Partial Dependence
- Imputing missing values before building an estimator
- Plotting Cross-Validated Predictions
- Cross-validation on diabetes Dataset Exercise
sklearn.datasets.load_digits

**sklearn.datasets.load_digits**, *n_class=10, return_X_y=False, as_frame=False*

Load and return the digits dataset (classification).

Each datapoint is a 8x8 image of a digit.

<table>
<thead>
<tr>
<th>Classes</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples per class</td>

</tbody>
</table>

Read more in the *User Guide*.

**Parameters**

- **n_class** [int, default=10] The number of classes to return. Between 0 and 10.
- **return_X_y** [bool, default=False] If True, returns *(data, target)* instead of a Bunch object. See below for more information about the data and target object.
  
  New in version 0.18.
- **as_frame** [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then *(data, target)* will be pandas DataFrames or Series as described below.
  
  New in version 0.23.

**Returns**

- **data** [*Bunch*] Dictionary-like object, with the following attributes.
  
  - **data** [[ndarray, dataframe] of shape (1797, 64)] The flattened data matrix. If as_frame=True, data will be a pandas DataFrame.
  - **target**: [ndarray, Series] of shape (1797,) The classification target. If as_frame=True, target will be a pandas Series.
  - **feature_names**: list The names of the dataset columns.
  - **target_names**: list The names of target classes.
    
    New in version 0.20.
  - **frame**: DataFrame of shape (1797, 65) Only present when as_frame=True. DataFrame with data and target.
    
    New in version 0.23.
  - **images**: [ndarray] of shape (1797, 8, 8) The raw image data.
  - **DESCR**: str The full description of the dataset.
  - **(data, target)** [tuple if return_X_y is True] New in version 0.18.

This is a copy of the test set of the UCI ML hand-written digits datasets

Examples

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_digits
>>> digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```

Examples using `sklearn.datasets.load_digits`

- Recognizing hand-written digits
- Feature agglomeration
- Various Agglomerative Clustering on a 2D embedding of digits
- A demo of K-Means clustering on the handwritten digits data
- The Digit Dataset
- Early stopping of Gradient Boosting
- Recursive feature elimination

- Dimensionality Reduction with Neighborhood Components Analysis
- Restricted Boltzmann Machine features for digit classification
- Compare Stochastic learning strategies for MLPClassifier
- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
sklearn.datasets.load_files

`sklearn.datasets.load_files(container_path, *, description=None, categories=None, load_content=True, shuffle=True, encoding=None, decode_error='strict', random_state=0)`

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

```
container_folder/
  category_1_folder/  file_1.txt file_2.txt ... file_42.txt
  category_2_folder/  file_43.txt file_44.txt ...
```

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if load_content is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the :mod:`sklearn.feature_extraction.text` module to build a feature extraction transformer that suits your problem.

If you set load_content=True, you should also specify the encoding of the text using the ‘encoding’ parameter. For many modern text files, ‘utf-8’ will be the correct encoding. If you leave encoding equal to None, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in text.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the User Guide.

Parameters

- **container_path** [str or unicode] Path to the main folder holding one subfolder per category
- **description** [str or unicode, default=None] A paragraph describing the characteristic of the dataset: its source, reference, etc.
- **categories** [list of str, default=None] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).
- **load_content** [bool, default=True] Whether to load or not the content of the different files. If true a ‘data’ attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.
- **shuffle** [bool, default=True] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.
- **encoding** [str, default=None] If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if load_content is True.
- **decode_error** [‘strict’, ‘ignore’, ‘replace’], default=’strict’] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. Passed as keyword argument ‘errors’ to bytes.decode.
random_state [int, RandomState instance or None, default=0] Determines random number
generation for dataset shuffling. Pass an int for reproducible output across multiple function
calls. See Glossary.

Returns
data [Bunch] Dictionary-like object, with the following attributes.

data [list of str] Only present when load_content=True. The raw text data to learn.
target [ndarray] The target labels (integer index).
target_names [list] The names of target classes.
DESCR [str] The full description of the dataset.
filenames: ndarray The filenames holding the dataset.

sklearn.datasets.load_iris

sklearn.datasets.load_iris (*, return_X_y=False, as_frame=False)
Load and return the iris dataset (classification).
The iris dataset is a classic and very easy multi-class classification dataset.

<table>
<thead>
<tr>

<td>real, positive</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch ob-
ject. See below for more information about the data and target object.
New in version 0.18.
as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with
appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the
number of target columns. If return_X_y is True, then (data, target) will be pandas
DataFrames or Series as described below.
New in version 0.23.

Returns
data [Bunch] Dictionary-like object, with the following attributes.
data [{ndarray, dataframe} of shape (150, 4)] The data matrix. If as_frame=True,
data will be a pandas DataFrame.
target: {ndarray, Series} of shape (150,) The classification target. If as_frame=True,
target will be a pandas Series.

feature_names: list The names of the dataset columns.
target_names: list The names of target classes.
frame: DataFrame of shape (150, 5) Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

DESCR: str The full description of the dataset.

filename: str The path to the location of the data.

New in version 0.20.

(data, target) [tuple if return_X_y is True] New in version 0.18.

Notes

Changed in version 0.20: Fixed two wrong data points according to Fisher’s paper. The new version is the same as in R, but not as in the UCI Machine Learning Repository.

Examples

Let’s say you are interested in the samples 10, 25, and 50, and want to know their class name.

```python
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
array([0, 0, 1])
>>> list(data.target_names)
['setosa', 'versicolor', 'virginica']
```

Examples using sklearn.datasets.load_iris

- Release Highlights for scikit-learn 0.22
- Plot classification probability
- Plot Hierarchical Clustering Dendrogram
- K-means Clustering
- The Iris Dataset
- Plot the decision surface of a decision tree on the iris dataset
- Understanding the decision tree structure
- PCA example with Iris Data-set
- Incremental PCA
- Comparison of LDA and PCA 2D projection of Iris dataset
- Factor Analysis (with rotation) to visualize patterns
- Plot the decision boundaries of a VotingClassifier
- Early stopping of Gradient Boosting
- Plot the decision surfaces of ensembles of trees on the iris dataset
- Test with permutations the significance of a classification score
- Univariate Feature Selection
sklearn.datasets.load_linnerud

sklearn.datasets.load_linnerud(*, return_X_y=False, as_frame=False)

Load and return the physical exercise linnerud dataset.

This dataset is suitable for multi-output regression tasks.

<table>
<thead>
<tr>
<th>Samples total</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>3 (for both data and target)</td>
</tr>
<tr>

<td>integer</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

**Parameters**

- **return_X_y** [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

  New in version 0.18.
as_frame  [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.

New in version 0.23.

Returns

data  [Bunch] Dictionary-like object, with the following attributes.

data  [[ndarray, dataframe] of shape (20, 3)] The data matrix. If as_frame=True, data will be a pandas DataFrame.

target: [ndarray, dataframe] of shape (20, 3) The regression targets. If as_frame=True, target will be a pandas DataFrame.

feature_names: list The names of the dataset columns.

target_names: list The names of the target columns.

frame: DataFrame of shape (20, 6) Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

DESCR: str The full description of the dataset.

data_filename: str The path to the location of the data.

target_filename: str The path to the location of the target.

New in version 0.20.

(data, target) [tuple if return_X_y is True] New in version 0.18.

8. sklearn.datasets

sklearn.datasets.load_sample_image

sklearn.datasets.load_sample_image(image_name)

Load the numpy array of a single sample image

Read more in the User Guide.

Parameters

image_name  [[china.jpg, flower.jpg]] The name of the sample image loaded

Returns

img  [3D array] The image as a numpy array: height x width x color

Examples

```python
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')
>>> china.dtype
dtype('uint8')
>>> china.shape
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg')
>>> flower.dtype
dtype('uint8')
```
Examples using `sklearn.datasets.load_sample_image`

- **Color Quantization using K-Means**

`sklearn.datasets.load_sample_images`

`sklearn.datasets.load_sample_images()`

Load sample images for image manipulation.

Loads both, `china` and `flower`.

Read more in the User Guide.

Returns

- **data** [Bunch] Dictionary-like object, with the following attributes.
  - **images** [list of ndarray of shape (427, 640, 3)] The two sample image.
  - **filenames** [list] The filenames for the images.
  - **DESCR** [str] The full description of the dataset.

Examples

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_sample_images
>>> dataset = load_sample_images()
>>> len(dataset.images)
2
>>> first_img_data = dataset.images[0]
>>> first_img_data.shape
(427, 640, 3)
>>> first_img_data.dtype
dtype('uint8')
```

`sklearn.datasets.load_svmlight_file`

`sklearn.datasets.load_svmlight_file(f, *, n_features=None, dtype=<class 'numpy.float64'>, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)`

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.
Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with joblib.Memory.cache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

https://github.com/mblondel/svmlight-loader

Parameters

- **f** [str, file-like or int] (Path to) a file to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

- **n_features** [int, default=None] The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. n_features is only required if offset or length are passed a non-default value.

- **dtype** [numpy data type, default=np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays X and y.

- **multilabel** [bool, default=False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

- **zero_based** [bool or “auto”, default=”auto”] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length are passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

- **query_id** [bool, default=False] If True, will return the query_id array for each file.

- **offset** [int, default=0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

- **length** [int, default=-1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

- **X** [scipy.sparse matrix of shape (n_samples, n_features)]

- **y** [ndarray of shape (n_samples,), or, in the multilabel a list of] tuples of length n_samples.

- **query_id** [array of shape (n_samples,)] query_id for each sample. Only returned when query_id is set to True.

See also:

7.7. sklearn.datasets: Datasets
**load_svmlight_files**  Similar function for loading multiple files in this format, enforcing the same number of features/columns on all of them.

### Examples

To use joblib.Memory to cache the svmlight file:

```python
from joblib import Memory
from .datasets import load_svmlight_file

mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

### sklearn.datasets.load_svmlight_files

**sklearn.datasets.load_svmlight_files** *(files, *, n_features=None, dtype=np.float64, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)*

Load dataset from multiple files in SVMlight format

This function is equivalent to mapping load_svmlight_file over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as in the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

**Parameters**

- **files** [array-like, dtype=str, file-like or int] (Paths of) files to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-likes and file descriptors will not be closed by this function. File-like objects must be opened in binary mode.

- **n_features** [int, default=None] The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

  This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

- **dtype** [numpy data type, default=np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays X and y.

- **multilabel** [bool, default=False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

- **zero_based** [bool or “auto”, default=”auto”] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length
is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

**query_id**  [bool, default=False] If True, will return the query_id array for each file.

**offset**  [int, default=0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

**length**  [int, default=-1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

**Returns**

[X1, y1, ..., Xn, yn]

where each (Xi, yi) pair is the result from load_svmlight_file(files[i]).

If query_id is set to True, this will return instead [X1, y1, q1, ...

..., Xn, yn, qn] where (Xi, yi, qi) is the result from load_svmlight_file(files[i])

**See also:**

load_svmlight_file

**Notes**

When fitting a model to a matrix X_train and evaluating it against a matrix X_test, it is essential that X_train and X_test have the same number of features (X_train.shape[1] == X_test.shape[1]). This may not be the case if you load the files individually with load_svmlight_file.

**sklearn.datasets.load_wine**

sklearn.datasets.load_wine(*, return_X_y=False, as_frame=False)

Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

| Classes | 3 |
| Samples per class | 59, 71, 48 |
| Samples total | 178 |
| Dimensionality | 13 |
| Features | real, positive |

Read more in the **User Guide**.

**Parameters**

**return_X_y**  [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

**as_frame**  [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.
Returns

data [Bunch] Dictionary-like object, with the following attributes.

data [[ndarray, dataframe] of shape (178, 13)] The data matrix. If as_frame=True, data will be a pandas DataFrame.

target: [ndarray, Series] of shape (178,) The classification target. If as_frame=True, target will be a pandas Series.

feature_names: list The names of the dataset columns.

target_names: list The names of target classes.

frame: DataFrame of shape (178, 14) Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

DESCR: str The full description of the dataset.

(data, target) [tuple if return_X_y is True]

The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit standard format from:

Examples

Let's say you are interested in the samples 10, 80, and 140, and want to know their class name.

```python
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

Examples using sklearn.datasets.load_wine

- Outlier detection on a real data set
- ROC Curve with Visualization API
- Importance of Feature Scaling
7.7.2 Samples generator

```python
datasets.make_biclusters(shape, n_clusters, *, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)
```

Generate an array with constant block diagonal structure for biclustering.

Read more in the User Guide.

**Parameters**

- `shape` [iterable of shape (n_rows, n_cols)] The shape of the result.
- `n_clusters` [int] The number of biclusters.
- `noise` [float, default=0.0] The standard deviation of the gaussian noise.
maxval  [int, default=100] Maximum value of a bicluster.
shuffle  [bool, default=True] Shuffle the samples.
random_state  [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X  [ndarray of shape shape] The generated array.
rows  [ndarray of shape (n_clusters, X.shape[0])] The indicators for cluster membership of each row.
cols  [ndarray of shape (n_clusters, X.shape[1])] The indicators for cluster membership of each column.

See also:

make_checkerboard

References

Examples using sklearn.datasets.make_biclusters

• A demo of the Spectral Co-Clustering algorithm

sklearn.datasets.make_blobs

sklearn.datasets.make_blobs(n_samples=100, n_features=2, *, centers=None, cluster_std=1.0, center_box=(-10.0, 10.0), shuffle=True, random_state=None, return_centers=False)

Generate isotropic Gaussian blobs for clustering.

Read more in the User Guide.

Parameters

n_samples  [int or array-like, default=100] If int, it is the total number of points equally divided among clusters. If array-like, each element of the sequence indicates the number of samples per cluster.

Changed in version v0.20: one can now pass an array-like to the n_samples parameter

n_features  [int, default=2] The number of features for each sample.

centers  [int or ndarray of shape (n_centers, n_features), default=None] The number of centers to generate, or the fixed center locations. If n_samples is an int and centers is None, 3 centers are generated. If n_samples is array-like, centers must be either None or an array of length equal to the length of n_samples.

cluster_std  [float or array-like of float, default=1.0] The standard deviation of the clusters.

center_box  [tuple of float (min, max), default=(-10.0, 10.0)] The bounding box for each cluster center when centers are generated at random.

shuffle  [bool, default=True] Shuffle the samples.
random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

return_centers [bool, default=False] If True, then return the centers of each cluster

New in version 0.23.

Returns

X [ndarray of shape (n_samples, n_features)] The generated samples.

y [ndarray of shape (n_samples,)] The integer labels for cluster membership of each sample.

centers [ndarray of shape (n_centers, n_features)] The centers of each cluster. Only returned if return_centers=True.

See also:

make_classification A more intricate variant.

Examples

```python
>>> from sklearn.datasets import make_blobs
>>> X, y = make_blobs(n_samples=10, centers=3, n_features=2,
...                   random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 0, 1, 0, 2, 2, 2, 1, 1, 0])
>>> X, y = make_blobs(n_samples=[3, 3, 4], centers=None, n_features=2,
...                   random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 1, 2, 0, 2, 2, 2, 1, 1, 0])
```

sklearn.datasets.make_checkerboard

sklearn.datasets.make_checkerboard(shape, n_clusters, *, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)

Generate an array with block checkerboard structure for biclustering.

Read more in the User Guide.

Parameters

- **shape** [tuple of shape (n_rows, n_cols)] The shape of the result.
- **n_clusters** [int or array-like or shape (n_row_clusters, n_column_clusters)] The number of row and column clusters.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise.
- **minval** [int, default=10] Minimum value of a bicluster.
- **maxval** [int, default=100] Maximum value of a bicluster.
- **shuffle** [bool, default=True] Shuffle the samples.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape shape] The generated array.
- **rows** [ndarray of shape (n_clusters, X.shape[0])] The indicators for cluster membership of each row.
- **cols** [ndarray of shape (n_clusters, X.shape[1])] The indicators for cluster membership of each column.

- A demo of the Spectral Biclustering algorithm

sklearn.datasets.make_checkerboard

Examples using sklearn.datasets.make_circles

- A simple toy dataset to visualize clustering and classification algorithms.
  - Read more in the User Guide.

Parameters

- **n_samples** [int or tuple of shape (2,), dtype=int, default=100] If int, it is the total number of points generated. For odd numbers, the inner circle will have one point more than the outer circle. If two-element tuple, number of points in outer circle and inner circle.
  - Changed in version 0.23: Added two-element tuple.
- **shuffle** [bool, default=True] Whether to shuffle the samples.
- **noise** [float, default=None] Standard deviation of Gaussian noise added to the data.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See Glossary.
- **factor** [float, default=.8] Scale factor between inner and outer circle in the range \((0, 1)\).

Returns

- **X** [ndarray of shape \((n_samples, 2)\)] The generated samples.
- **y** [ndarray of shape \((n_samples,)\)] The integer labels (0 or 1) for class membership of each sample.

Examples using sklearn.datasets.make_circles

- Classifier comparison
- Comparing different hierarchical linkage methods on toy datasets
- Comparing different clustering algorithms on toy datasets
- Kernel PCA
- Hashing feature transformation using Totally Random Trees
- t-SNE: The effect of various perplexity values on the shape

- Varying regularization in Multi-layer Perceptron
sklearn.datasets.make_classification

Generate a random n-class classification problem.

This initially creates clusters of points normally distributed (std=1) about vertices of an n_informative-dimensional hypercube with sides of length 2\times class_sep and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Without shuffling, X horizontally stacks features in the following order: the primary n_informative features, followed by n_redundant linear combinations of the informative features, followed by n_repeated duplicates, drawn randomly with replacement from the informative and redundant features. The remaining features are filled with random noise. Thus, without shuffling, all useful features are contained in the columns X[:, :n_informative + n_redundant + n_repeated].

Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **n_features** [int, default=20] The total number of features. These comprise n_informative informative features, n_redundant redundant features, n_repeated duplicated features and n_features-n_informative-n_redundant-n_repeated useless features drawn at random.
- **n_informative** [int, default=2] The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension n_informative. For each cluster, informative features are drawn independently from N(0, 1) and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.
- **n_redundant** [int, default=2] The number of redundant features. These features are generated as random linear combinations of the informative features.
- **n_repeated** [int, default=0] The number of duplicated features, drawn randomly from the informative and the redundant features.
- **n_classes** [int, default=2] The number of classes (or labels) of the classification problem.
- **n_clusters_per_class** [int, default=2] The number of clusters per class.
- **weights** [array-like of shape (n_classes,) or (n_classes - 1,), default=None] The proportions of samples assigned to each class. If None, then classes are balanced. Note that if len(weights) == n_classes - 1, then the last class weight is automatically inferred. More than n_samples samples may be returned if the sum of weights exceeds 1.
- **flip_y** [float, default=0.01] The fraction of samples whose class is assigned randomly. Larger values introduce noise in the labels and make the classification task harder. Note that the default setting flip_y > 0 might lead to less than n_classes in y in some cases.
class_sep [float, default=1.0] The factor multiplying the hypercube size. Larger values spread out the clusters/classes and make the classification task easier.

hypercube [bool, default=True] If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.

shift [float, ndarray of shape (n_features,) or None, default=0.0] Shift features by the specified value. If None, then features are shifted by a random value drawn in [-class_sep, class_sep].

scale [float, ndarray of shape (n_features,) or None, default=1.0] Multiply features by the specified value. If None, then features are scaled by a random value drawn in [1, 100]. Note that scaling happens after shifting.

shuffle [bool, default=True] Shuffle the samples and the features.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [ndarray of shape (n_samples, n_features)] The generated samples.

y [ndarray of shape (n_samples,)] The integer labels for class membership of each sample.

See also:

make_blobs Simplified variant.

make_multilabel_classification Unrelated generator for multilabel tasks.

Notes

The algorithm is adapted from Guyon [1] and was designed to generate the “Madelon” dataset.

sklearn.datasets.make_friedman1

Generate the “Friedman #1” regression problem.

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are independent features uniformly distributed on the interval [0, 1]. The output y is created according to the formula:

\[
y(X) = 10 \times \sin(\pi \times X[:, 0] \times X[:, 1]) + 20 \times (X[:, 2] - 0.5)^2 + 10 \times X[:, \rightarrow 3] + 5 \times X[:, 4] + \text{noise} \times N(0, 1).
\]

Out of the n_features features, only 5 are actually used to compute y. The remaining features are independent of y.

The number of features has to be >= 5.

Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **n_features** [int, default=10] The number of features. Should be at least 5.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, n_features)] The input samples.
- **y** [ndarray of shape (n_samples,)] The output values.

References

[1], [2]
sklearn.datasets.make_friedman2

sklearn.datasets.make_friedman2(n_samples=100, *, noise=0.0, random_state=None)
Generate the “Friedman #2” regression problem.

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are 4 independent features uniformly distributed on the intervals:

\[
\begin{align*}
0 & \leq X[:, 0] \leq 100, \\
40 \cdot \pi & \leq X[:, 1] \leq 560 \cdot \pi, \\
0 & \leq X[:, 2] \leq 1, \\
1 & \leq X[:, 3] \leq 11.
\end{align*}
\]

The output y is created according to the formula:

\[
y(X) = (X[:, 0] \cdot X[:, 1] \cdot X[:, 2] - 1 / (X[:, 1] \cdot X[:, 3])) \cdot 2 + 5 + \text{noise} \cdot N(0, 1).
\]

Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, 4)] The input samples.
- **y** [ndarray of shape (n_samples,)] The output values.

References

[1], [2]

sklearn.datasets.make_friedman3

sklearn.datasets.make_friedman3(n_samples=100, *, noise=0.0, random_state=None)
Generate the “Friedman #3” regression problem.

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are 4 independent features uniformly distributed on the intervals:

\[
\begin{align*}
0 & \leq X[:, 0] \leq 100, \\
40 \cdot \pi & \leq X[:, 1] \leq 560 \cdot \pi, \\
0 & \leq X[:, 2] \leq 1, \\
1 & \leq X[:, 3] \leq 11.
\end{align*}
\]

The output y is created according to the formula:

\[
y(X) = \arctan((X[:, 1] \cdot X[:, 2] - 1 / (X[:, 1] \cdot X[:, 3])) / X[:, 0]) + \text{noise} \cdot N(0, 1).
\]
**Parameters**

- **n_samples** [int, default=100] The number of samples.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- **X** [ndarray of shape (n_samples, 4)] The input samples.
- **y** [ndarray of shape (n_samples,)] The output values.

**References**

[1], [2]

```python
def make_gaussian_quantiles(*, mean=None, cov=1.0, n_samples=100, n_features=2, n_classes=3, shuffle=True, random_state=None)
```

Generate isotropic Gaussian and label samples by quantile.

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the $\chi^2$ distribution).

**Parameters**

- **mean** [ndarray of shape (n_features,), default=None] The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).
- **cov** [float, default=1.0] The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.
- **n_samples** [int, default=100] The total number of points equally divided among classes.
- **n_features** [int, default=2] The number of features for each sample.
- **n_classes** [int, default=3] The number of classes
- **shuffle** [bool, default=True] Shuffle the samples.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- **X** [ndarray of shape (n_samples, n_features)] The generated samples.
- **y** [ndarray of shape (n_samples,)] The integer labels for quantile membership of each sample.
Notes

The dataset is from Zhu et al [1].

sklearn.datasets.make_hastie_10_2

sklearn.datasets.make_hastie_10_2 (n_samples=12000, *, random_state=None)

Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target \( y \) is defined by:

\[ y[i] = 1 \quad \text{if} \quad \text{np.sum}(X[i] ** 2) > 9.34 \quad \text{else} \quad -1 \]

Read more in the User Guide.

Parameters

- **n_samples** [int, default=12000] The number of samples.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, 10)] The input samples.
- **y** [ndarray of shape (n_samples,)] The output values.

`sunless.datasets.make_low_rank_matrix`

`sunless.datasets.make_low_rank_matrix`(`n_samples=100`, `n_features=100`, *, `effective_rank=10`, `tail_strength=0.5`, `random_state=None`)

Generate a mostly low rank matrix with bell-shaped singular values.

Most of the variance can be explained by a bell-shaped curve of width `effective_rank`: the low rank part of the singular values profile is:

\[(1 - \text{tail_strength}) \times \exp(-1.0 \times (i / \text{effective_rank}) ** 2)\]

The remaining singular values’ tail is fat, decreasing as:

\[\text{tail_strength} \times \exp(-0.1 \times i / \text{effective_rank}).\]

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

This kind of singular profiles is often seen in practice, for instance:

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **n_features** [int, default=100] The number of features.
- **effective_rank** [int, default=10] The approximate number of singular vectors required to explain most of the data by linear combinations.
- **tail_strength** [float, default=0.5] The relative importance of the fat noisy tail of the singular values profile. The value should be between 0 and 1.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, n_features)] The matrix.
sklearn.datasets.make_moons

Make two interleaving half circles.
A simple toy dataset to visualize clustering and classification algorithms. Read more in the User Guide.

Parameters

n_samples [int or tuple of shape (2,), dtype=int, default=100] If int, the total number of points generated. If two-element tuple, number of points in each of two moons.

Changed in version 0.23: Added two-element tuple.

shuffle [bool, default=True] Whether to shuffle the samples.

noise [float, default=None] Standard deviation of Gaussian noise added to the data.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [ndarray of shape (n_samples, 2)] The generated samples.

y [ndarray of shape (n_samples,)] The integer labels (0 or 1) for class membership of each sample.

Examples using sklearn.datasets.make_moons

- Classifier comparison
- Comparing different hierarchical linkage methods on toy datasets
- Comparing different clustering algorithms on toy datasets
- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Compare Stochastic learning strategies for MLPClassifier
- Varying regularization in Multi-layer Perceptron
- Feature discretization

sklearn.datasets.make_multilabel_classification

Generate a random multilabel classification problem.

For each sample, the generative process is:

- pick the number of labels: n ~ Poisson(n_labels)
- n times, choose a class c: c ~ Multinomial(theta)
- pick the document length: k ~ Poisson(length)
• k times, choose a word: \( w \sim \text{Multinomial}(\theta_c) \)

In the above process, rejection sampling is used to make sure that \( n \) is never zero or more than \( n_{\text{classes}} \), and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the User Guide.

Parameters

- \( n_{\text{samples}} \) [int, default=100] The number of samples.
- \( n_{\text{features}} \) [int, default=20] The total number of features.
- \( n_{\text{classes}} \) [int, default=5] The number of classes of the classification problem.
- \( n_{\text{labels}} \) [int, default=2] The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with \( n_{\text{labels}} \) as its expected value, but samples are bounded (using rejection sampling) by \( n_{\text{classes}} \), and must be nonzero if \( \text{allow_unlabeled} \) is False.
- \( \text{length} \) [int, default=50] The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.
- \( \text{allow_unlabeled} \) [bool, default=True] If True, some instances might not belong to any class.
- \( \text{sparse} \) [bool, default=False] If True, return a sparse feature matrix

    New in version 0.17: parameter to allow sparse output.
- \( \text{return_indicator} \) [{'dense', 'sparse'} or False, default='dense'] If 'dense' return \( Y \) in the dense binary indicator format. If 'sparse' return \( Y \) in the sparse binary indicator format. False returns a list of lists of labels.
- \( \text{return_distributions} \) [bool, default=False] If True, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.
- \( \text{random_state} \) [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- \( X \) [ndarray of shape \((n_{\text{samples}}, n_{\text{features}})\)] The generated samples.
- \( Y \) [(ndarray, sparse matrix) of shape \((n_{\text{samples}}, n_{\text{classes}})\)] The label sets. Sparse matrix should be of CSR format.
- \( p_c \) [ndarray of shape \((n_{\text{classes}},)\)] The probability of each class being drawn. Only returned if return_distributions=True.
- \( p_{w,c} \) [ndarray of shape \((n_{\text{features}}, n_{\text{classes}})\)] The probability of each feature being drawn given each class. Only returned if return_distributions=True.
scikit-learn user guide, Release 0.24.dev0

Examples using `sklearn.datasets.make_multilabel_classification`

- Plot randomly generated multilabel dataset
- Multilabel classification

`sklearn.datasets.make_regression`

```python
sklearn.datasets.make_regression(n_samples=100, n_features=100, *, n_informative=10, n_targets=1, bias=0.0, effective_rank=None, tail_strength=0.5, noise=0.0, shuffle=True, coef=False, random_state=None)
```

Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See `make_low_rank_matrix` for more details.

The output is generated by applying a (potentially biased) random linear regression model with `n_informative` nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the User Guide.

Parameters

- `n_samples` [int, default=100] The number of samples.
- `n_features` [int, default=100] The number of features.
- `n_informative` [int, default=10] The number of informative features, i.e., the number of features used to build the linear model used to generate the output.
- `n_targets` [int, default=1] The number of regression targets, i.e., the dimension of the y output vector associated with a sample. By default, the output is a scalar.
- `bias` [float, default=0.0] The bias term in the underlying linear model.
- `effective_rank` [int, default=None]
  - if not None: The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.
  - if None: The input set is well conditioned, centered and gaussian with unit variance.
- `tail_strength` [float, default=0.5] The relative importance of the fat noisy tail of the singular values profile if `effective_rank` is not None. When a float, it should be between 0 and 1.
- `noise` [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- `shuffle` [bool, default=True] Shuffle the samples and the features.
- `coef` [bool, default=False] If True, the coefficients of the underlying linear model are returned.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- `X` [ndarray of shape (n_samples, n_features)] The input samples.
- `y` [ndarray of shape (n_samples,) or (n_samples, n_targets)] The output values.
coef [ndarray of shape (n_features,) or (n_features, n_targets)] The coefficient of the underlying linear model. It is returned only if coef is True.

Examples using sklearn.datasets.make_regression

- Release Highlights for scikit-learn 0.23
- Prediction Latency
- Plot Ridge coefficients as a function of the L2 regularization
- Robust linear model estimation using RANSAC
- HuberRegressor vs Ridge on dataset with strong outliers
- Lasso on dense and sparse data
- Effect of transforming the targets in regression model

sklearn.datasets.make_s_curve

sklearn.datasets.make_s_curve(n_samples=100, *, noise=0.0, random_state=None)

Generate an S curve dataset.

Read more in the User Guide.

Parameters

- n_samples [int, default=100] The number of sample points on the S curve.
- noise [float, default=0.0] The standard deviation of the gaussian noise.
- random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- X [ndarray of shape (n_samples, 3)] The points.
- t [ndarray of shape (n_samples,)] The univariate position of the sample according to the main dimension of the points in the manifold.

Examples using sklearn.datasets.make_s_curve

- Comparison of Manifold Learning methods
- t-SNE: The effect of various perplexity values on the shape
sklearn.datasets.make_sparse_coded_signal

Parameters

- `n_samples` [int] Number of samples to generate
- `n_components` [int] Number of components in the dictionary
- `n_features` [int] Number of features of the dataset to generate
- `n_nonzero_coefs` [int] Number of active (non-zero) coefficients in each sample
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- `data` [ndarray of shape (n_features, n_samples)] The encoded signal (Y).
- `dictionary` [ndarray of shape (n_features, n_components)] The dictionary with normalized components (D).
- `code` [ndarray of shape (n_components, n_samples)] The sparse code such that each column of this matrix has exactly n_nonzero_coefs non-zero items (X).

Examples using sklearn.datasets.make_sparse_coded_signal

- Orthogonal Matching Pursuit

sklearn.datasets.make_sparse_spd_matrix

Parameters

- `dim` [int, default=1] The size of the random matrix to generate.
- `alpha` [float, default=0.95] The probability that a coefficient is zero (see notes). Larger values enforce more sparsity. The value should be in the range 0 and 1.
- `norm_diag` [bool, default=False] Whether to normalize the output matrix to make the leading diagonal elements all 1
- `smallest_coef` [float, default=0.1] The value of the smallest coefficient between 0 and 1.
- `largest_coef` [float, default=0.9] The value of the largest coefficient between 0 and 1.
**random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

prec [sparse matrix of shape (dim, dim)] The generated matrix.

**See also:**

* make_spd_matrix

**Notes**

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into the filling fraction of the matrix itself.

**Examples using sklearn.datasets.make_sparse_spd_matrix**

- Sparse inverse covariance estimation

**sklearn.datasets.make_sparse_uncorrelated**

**Parameters**

- n_samples [int, default=100] The number of samples.
- n_features [int, default=10] The number of features.
- random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- X [ndarray of shape (n_samples, n_features)] The input samples.
- y [ndarray of shape (n_samples,)] The output values.

X ~ N(0, 1)
y(X) = X[:, 0] + 2 * X[:, 1] - 2 * X[:, 2] - 1.5 * X[:, 3]
References

[1]

**sklearn.datasets.make_spd_matrix**

*sklearn.datasets.make_spd_matrix*(n_dim, *, random_state=None)*

Generate a random symmetric, positive-definite matrix.

Read more in the *User Guide*.

**Parameters**

- **n_dim** [int] The matrix dimension.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- **X** [ndarray of shape (n_dim, n_dim)] The random symmetric, positive-definite matrix.

See also:

*make_sparse_spd_matrix*

**sklearn.datasets.make_swiss_roll**

*sklearn.datasets.make_swiss_roll*(n_samples=100, *, noise=0.0, random_state=None)*

Generate a swiss roll dataset.

Read more in the *User Guide*.

**Parameters**

- **n_samples** [int, default=100] The number of sample points on the S curve.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- **X** [ndarray of shape (n_samples, 3)] The points.
- **t** [ndarray of shape (n_samples,)] The univariate position of the sample according to the main dimension of the points in the manifold.
Notes

The algorithm is from Marsland [1].

[1]

Examples using sklearn.datasets.make_swiss_roll

- Hierarchical clustering: structured vs unstructured ward
- Swiss Roll reduction with LLE

7.8 sklearn.decomposition: Matrix Decomposition

The sklearn.decomposition module includes matrix decomposition algorithms, including among others PCA, NMF or ICA. Most of the algorithms of this module can be regarded as dimensionality reduction techniques.

User guide: See the Decomposing signals in components (matrix factorization problems) section for further details.

```
from sklearn.decomposition import DictionaryLearning

dictionary_learning = DictionaryLearning(**kwargs)
```

Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

\[
(U^*, V^*) = \arg \min_{U \in \mathbb{R}^{n \times d}, V \in \mathbb{R}^{d \times d}} 0.5 \| X - U V \|_F^2 + \alpha \| U \|_1 \| V \|_1
\]

with \( \| V_k \|_F = 1 \) for all \( 0 \leq k < n_{\text{components}} \)
Read more in the User Guide.

Parameters

- **n_components** [int, default=n_features] Number of dictionary elements to extract.
- **alpha** [float, default=1.0] Sparsity controlling parameter.
- **max_iter** [int, default=1000] Maximum number of iterations to perform.
- **tol** [float, default=1e-8] Tolerance for numerical error.
- **fit_algorithm** [{‘lars’, ‘cd’}, default=’lars’]
  - **lars**: uses the least angle regression method to solve the lasso problem
    (linear_model.lars_path);
  - **cd**: uses the coordinate descent method to compute the Lasso solution
    (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

  New in version 0.17: cd coordinate descent method to improve speed.
  Algorithm used to transform the data:
  - **lars**: uses the least angle regression method (linear_model.lars_path);
  - **lasso_lars**: uses Lars to compute the Lasso solution.
  - **lasso_cd**: uses the coordinate descent method to compute the Lasso solution
    (linear_model.Lasso). 'lasso_lars' will be faster if the estimated components are sparse.
  - **omp**: uses orthogonal matching pursuit to estimate the sparse solution.
  - **threshold**: squashes to zero all coefficients less than alpha from the projection
    dictionary * X'.

  New in version 0.17: lasso_cd coordinate descent method to improve speed.
- **transform_n_nonzero_coefs** [int, default=None] Number of nonzero coefficients to target
  in each column of the solution. This is only used by algorithm='lars' and
  algorithm='omp' and is overridden by alpha in the omp case. If None, then
  transform_n_nonzero_coefs=int(n_features / 10).
- **transform_alpha** [float, default=None] If algorithm='lasso_lars' or
  algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If
  algorithm='threshold', alpha is the absolute value of the threshold below
  which coefficients will be squashed to zero. If algorithm='omp', alpha is the
  tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides
  n_nonzero_coefs. If None, default to 1.0
- **n_jobs** [int or None, default=None] Number of parallel jobs to run. None means 1 unless in
  a joblib.parallel_backend context. -1 means using all processors. See Glossary
  for more details.
- **code_init** [ndarray of shape (n_samples, n_components), default=None] Initial value for the
  code, for warm restart.
- **dict_init** [ndarray of shape (n_components, n_features), default=None] Initial values for the
dictionary, for warm restart.
- **verbose** [bool, default=False] To control the verbosity of the procedure.
split_sign [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

random_state [int, RandomState instance or None, default=None] Used for initializing the dictionary when dict_init is not specified, randomly shuffling the data when shuffle is set to True, and updating the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

positive_dict [bool, default=False] Whether to enforce positivity when finding the dictionary

New in version 0.20.

transform_max_iter [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or 'lasso_lars'.

New in version 0.22.

Attributes

components_ [ndarray of shape (n_components, n_features)] dictionary atoms extracted from the data

error_ [array] vector of errors at each iteration

n_iter_ [int] Number of iterations run.

MiniBatchSparsePCA

Notes

References:

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_sparse_coded_signal
>>> from sklearn.decomposition import DictionaryLearning

>>> X, dictionary, code = make_sparse_coded_signal(n_samples=100, n_components=15, n_features=20, n_nonzero_coefs=10, random_state=42)

>>> dict_learner = DictionaryLearning(n_components=15, transform_algorithm='lasso_lars', random_state=42)

>>> X_transformed = dict_learner.fit_transform(X)
```
We can check the level of sparsity of $X_{\text{transformed}}$:

```python
>>> np.mean(X_transformed == 0)
0.88...
```

We can compare the average squared euclidean norm of the reconstruction error of the sparse coded signal relative to the squared euclidean norm of the original signal:

```python
>>> X_hat = X_transformed @ dict_learner.components_
>>> np.mean(np.sum((X_hat - X) ** 2, axis=1) / np.sum(X ** 2, axis=1))
0.07...
```

**Methods**

**fit** ($X$, $y$=None)

Fit the model from data in $X$.

**Parameters**

- $X$ [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- $y$ [Ignored]

**Returns**

- self [object] Returns the object itself.

**fit_transform** ($X$, $y$=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to $X$ and $y$ with optional parameters `fit_params` and returns a transformed version of $X$.

**Parameters**

- $X$ [array-like of shape (n_samples, n_features)] Input samples.

- $y$ [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

- **fit_params** [dict] Additional fit parameters.

**Returns**

- $X_{\text{new}}$ [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)

Encode the data as a sparse combination of the dictionary atoms. Coding method is determined by the object parameter transform_algorithm.

Parameters

X [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [ndarray of shape (n_samples, n_components)] Transformed data.

### 7.8.2 sklearn.decomposition.FactorAnalysis

class sklearn.decomposition.FactorAnalysis(**kwargs)

Factor Analysis (FA).

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain PPCA.

FactorAnalysis performs a maximum likelihood estimate of the so-called loading matrix, the transformation of the latent variables to the observed ones, using SVD based approach.

Read more in the User Guide.

New in version 0.13.

Parameters

n_components [int, default=None] Dimensionality of latent space, the number of components of X that are obtained after transform. If None, n_components is set to the number of features.

tol [float, default=1e-2] Stopping tolerance for log-likelihood increase.
copy [bool, default=True] Whether to make a copy of X. If False, the input X gets overwritten during fitting.

max_iter [int, default=1000] Maximum number of iterations.

noise_variance_init [ndarray of shape (n_features,), default=None] The initial guess of the noise variance for each feature. If None, it defaults to np.ones(n_features).

svd_method [('lapack', 'randomized'), default='randomized'] Which SVD method to use. If 'lapack' use standard SVD from scipy.linalg, if 'randomized' use fast randomized_svd function. Defaults to 'randomized'. For most applications 'randomized' will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for iterated_power. If this is not sufficient, for maximum precision you should choose 'lapack'.

iterated_power [int, default=3] Number of iterations for the power method. 3 by default. Only used if svd_method equals 'randomized'.

rotation [('varimax', 'quartimax'), default=None] If not None, apply the indicated rotation. Currently, varimax and quartimax are implemented. See “The varimax criterion for analytic rotation in factor analysis” H. F. Kaiser, 1958.

New in version 0.24.

random_state [int or RandomState instance, default=0] Only used when svd_method equals 'randomized'. Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes

components_ [ndarray of shape (n_components, n_features)] Components with maximum variance.

loglike_ [list of shape (n_iterations,) ] The log likelihood at each iteration.

noise_variance_ [ndarray of shape (n_features,) ] The estimated noise variance for each feature.

n_iter_ [int] Number of iterations run.

mean_ [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training set.

See also:

PCA Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

FastICA Independent component analysis, a latent variable model with non-Gaussian latent variables.

**fit** *(X, y=None)*

Fit the FactorAnalysis model to X using SVD based approach

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [Ignored]

**Returns**

- **self**

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.
get_covariance()
Compute data covariance with the FactorAnalysis model.

cov = components_.T * components_ + diag(noise_variance)

Returns

cov  [ndarray of shape (n_features, n_features)] Estimated covariance of data.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

get_precision()
Compute data precision matrix with the FactorAnalysis model.

Returns

precision  [ndarray of shape (n_features, n_features)] Estimated precision of data.

score (X, y=None)
Compute the average log-likelihood of the samples

Parameters

X  [ndarray of shape (n_samples, n_features)] The data

y  [Ignored]

Returns

ll  [float] Average log-likelihood of the samples under the current model

score_samples (X)
Compute the log-likelihood of each sample

Parameters

X  [ndarray of shape (n_samples, n_features)] The data

Returns

ll  [ndarray of shape (n_samples,)] Log-likelihood of each sample under the current model

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.
**transform**\((X)\)
Apply dimensionality reduction to \(X\) using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

**Parameters**

\(X\) [array-like of shape (n_samples, n_features)] Training data.

**Returns**

\(X\_\text{new}\) [ndarray of shape (n_samples, n_components)] The latent variables of \(X\).

**Examples using sklearn.decomposition.FactorAnalysis**

- *Factor Analysis (with rotation) to visualize patterns*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Faces dataset decompositions*

### 7.8.3 sklearn.decomposition.FastICA

class sklearn.decomposition.FastICA(**kwargs)
FastICA: a fast algorithm for Independent Component Analysis.

**Parameters**

- **n_components** [int, default=None] Number of components to use. If None is passed, all are used.
- **algorithm** [{'parallel', 'deflation'}, default='parallel'] Apply parallel or deflational algorithm for FastICA.
- **whiten** [bool, default=True] If whiten is false, the data is already considered to be whitened, and no whitening is performed.
- **fun** ['logcosh', 'exp', 'cube'] or callable, default='logcosh' The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

```python
def my_g(x):
    return x ** 3, (3 * x ** 2).mean(axis=-1)
```

- **fun_args** [dict, default=None] Arguments to send to the functional form. If empty and if `fun='logcosh'`, `fun_args` will take value {‘alpha’: 1.0}.
- **max_iter** [int, default=200] Maximum number of iterations during fit.
- **tol** [float, default=1e-4] Tolerance on update at each iteration.
- **w_init** [ndarray of shape (n_components, n_components), default=None] The mixing matrix to be used to initialize the algorithm.
- **random_state** [int, RandomState instance or None, default=None] Used to initialize \(w\_\text{init}\) when not specified, with a normal distribution. Pass an int, for reproducible results across multiple function calls. See [Glossary](https://scikit-learn.org/stable/glossary.html).

**Attributes**
components_ [ndarray of shape (n_components, n_features)] The linear operator to apply to the data to get the independent sources. This is equal to the unmixing matrix when whiten is False, and equal to np.dot(unmixing_matrix, self.whitening_) when whiten is True.

mixing_ [ndarray of shape (n_features, n_components)] The pseudo-inverse of components_. It is the linear operator that maps independent sources to the data.

mean_ [ndarray of shape(n_features,)] The mean over features. Only set if self.whiten is True.

n_iter_ [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

whitening_ [ndarray of shape (n_components, n_features)] Only set if whiten is ‘True’. This is the pre-whitening matrix that projects data onto the first n_components principal components.

Notes

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FastICA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FastICA(n_components=7,
...                       random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored]
Returns

self

**fit_transform** *(X, y=None)*
Fit the model and recover the sources from X.

Parameters

**X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**y** [Ignored]

Returns

**X_new** [ndarray of shape (n_samples, n_components)]

**get_params** *(deep=True)*
Get parameters for this estimator.

Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**inverse_transform** *(X, copy=True)*
Transform the sources back to the mixed data (apply mixing matrix).

Parameters

**X** [array-like of shape (n_samples, n_components)] Sources, where n_samples is the number of samples and n_components is the number of components.

**copy** [bool, default=True] If False, data passed to fit are overwritten. Defaults to True.

Returns

**X_new** [ndarray of shape (n_samples, n_features)]

**set_params** (**params**)
Set the parameters of this estimator.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

**transform** *(X, copy=True)*
Recover the sources from X (apply the unmixing matrix).

Parameters

**X** [array-like of shape (n_samples, n_features)] Data to transform, where n_samples is the number of samples and n_features is the number of features.

**copy** [bool, default=True] If False, data passed to fit can be overwritten. Defaults to True.
Returns

\(X_{\text{new}}\) [ndarray of shape (n_samples, n_components)]

Examples using `sklearn.decomposition.FastICA`

- Blind source separation using FastICA
- FastICA on 2D point clouds
- Faces dataset decompositions

### 7.8.4 sklearn.decomposition.IncrementalPCA

class sklearn.decomposition.IncrementalPCA(**kwargs)

Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of the data, keeping only the most significant singular vectors to project the data to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA, and allows sparse input.

This algorithm has constant memory complexity, on the order of \(\text{batch}_\text{size} * \text{n}_\text{features}\), enabling use of np.memmap files without loading the entire file into memory. For sparse matrices, the input is converted to dense in batches (in order to be able to subtract the mean) which avoids storing the entire dense matrix at any one time.

The computational overhead of each SVD is \(O(\text{batch}_\text{size} * \text{n}_\text{features} ** 2)\), but only \(2 * \text{batch}_\text{size}\) samples remain in memory at a time. There will be \(\text{n}_\text{samples} / \text{batch}_\text{size}\) SVD computations to get the principal components, versus 1 large SVD of complexity \(O(\text{n}_\text{samples} * \text{n}_\text{features} ** 2)\) for PCA.

Read more in the User Guide.

New in version 0.16.

Parameters

- **n_components** [int, default=None] Number of components to keep. If \(\text{n}_\text{components}\) is None, then \(\text{n}_\text{components}\) is set to \(\text{min}(\text{n}_\text{samples}, \text{n}_\text{features})\).

- **whiten** [bool, default=False] When True (False by default) the components_ vectors are divided by \(\text{n}_\text{samples} * \text{components}_\text{vector}\) to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.

- **copy** [bool, default=True] If False, X will be overwritten. copy=False can be used to save memory but is unsafe for general use.

- **batch_size** [int, default=None] The number of samples to use for each batch. Only used when calling fit. If batch_size is None, then batch_size is inferred from the data and set to \(5 * \text{n}_\text{features}\), to provide a balance between approximation accuracy and memory consumption.

Attributes
components_ [ndarray of shape (n_components, n_features)] Components with maximum variance.

explained_variance_ [ndarray of shape (n_components,)] Variance explained by each of the selected components.

explained_variance_ratio_ [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.

singular_values_ [ndarray of shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

mean_ [ndarray of shape (n_features,)] Per-feature empirical mean, aggregate over calls to partial_fit.

var_ [ndarray of shape (n_features,)] Per-feature empirical variance, aggregate over calls to partial_fit.

n_components_ [int] The estimated number of components. Relevant when n_components=None.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across partial_fit calls.

batch_size_ [int] Inferred batch size from batch_size.

TruncatedSVD

Notes

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is Matrix Computations, Third Edition, G. Holub and C. Van Loan, Chapter 5, section 5.4.4, pp 252-253.. This technique has been omitted because it is advantageous only when decomposing a matrix with n_samples (rows) >= S/3 * n_features (columns), and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

**fit** *(X, y=None)*

Fit the model with X, using minibatches of size batch_size.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored]

**Returns**

- **self** [object] Returns the instance itself.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.
Parameters

X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

generate_covariance()
Compute data covariance with the generative model.

cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)
where S**2 contains the explained variances, and sigma2 contains the noise variances.

Returns

cov [array, shape=(n_features, n_features)] Estimated covariance of data.

generate_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

generate_precision()
Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns

precision [array, shape=(n_features, n_features)] Estimated precision of data.

inverse_transform (X)
Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters

X [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

X_original array-like, shape (n_samples, n_features)
Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

partial_fit (X, y=None, check_input=True)
Incremental fit with X. All of X is processed as a single batch.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

check_input [bool, default=True] Run check_array on X.

y [Ignored]

Returns

self [object] Returns the instance itself.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set, using minibatches of size batch_size if X is sparse.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [ndarray of shape (n_samples, n_components)]

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2],
... [1, 1], [2, 1], [3, 2]]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X)
```
7.8.5 sklearn.decomposition.KernelPCA

class sklearn.decomposition.KernelPCA(**kwargs)
    Kernel Principal component analysis (KPCA).

    Non-linear dimensionality reduction through the use of kernels (see Pairwise metrics, Affinities and Kernels).
    Read more in the User Guide.

    Parameters

    n_components [int, default=None] Number of components. If None, all non-zero components are kept.

    kernel [['linear', 'poly', 'rbf', 'sigmoid', 'cosine', 'precomputed'], default='linear'] Kernel used for PCA.

    gamma [float, default=None] Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels. If gamma is None, then it is set to 1/n_features.

    degree [int, default=3] Degree for poly kernels. Ignored by other kernels.

    coef0 [float, default=1] Independent term in poly and sigmoid kernels. Ignored by other kernels.

    kernel_params [dict, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

    alpha [float, default=1.0] Hyperparameter of the ridge regression that learns the inverse transform (when fit_inverse_transform=True).

    fit_inverse_transform [bool, default=False] Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)

    eigen_solver [['auto', 'dense', 'arpack'], default='auto'] Select eigensolver to use. If n_components is much less than the number of training samples, arpack may be more efficient than the dense eigensolver.

    tol [float, default=0] Convergence tolerance for arpack. If 0, optimal value will be chosen by arpack.

    max_iter [int, default=None] Maximum number of iterations for arpack. If None, optimal value will be chosen by arpack.

    remove_zero_eig [bool, default=False] If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be < n_components (and sometimes even zero due to numerical instability). When n_components is None, this parameter is ignored and components with zero eigenvalues are removed regardless.

    random_state [int, RandomState instance or None, default=None] Used when eigen_solver == ‘arpack’. Pass an int for reproducible results across multiple function calls. See Glossary.

    New in version 0.18.

    copy_X [bool, default=True] If True, input X is copied and stored by the model in the X_fit_ attribute. If no further changes will be done to X, setting copy_X=False saves memory by storing a reference.

    New in version 0.18.
**n_jobs** [int, default=None] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

New in version 0.18.

**Attributes**

- **lambdas_** [ndarray of shape (n_components,)] Eigenvalues of the centered kernel matrix in decreasing order. If `n_components` and `remove_zero_eig` are not set, then all values are stored.

- **alphas_** [ndarray of shape (n_samples, n_components)] Eigenvectors of the centered kernel matrix. If `n_components` and `remove_zero_eig` are not set, then all components are stored.

- **dual_coef_** [ndarray of shape (n_samples, n_features)] Inverse transform matrix. Only available when `fit_inverse_transform` is True.

- **X_transformed_fit_** [ndarray of shape (n_samples, n_components)] Projection of the fitted data on the kernel principal components. Only available when `fit_inverse_transform` is True.

- **X_fit_** [ndarray of shape (n_samples, n_features)] The data used to fit the model. If `copy_X=False`, then `X_fit_` is a reference. This attribute is used for the calls to transform.

**References**

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import KernelPCA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = KernelPCA(n_components=7, kernel='linear')
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

**fit (X, y=None)**

- Fit the model from data in X.
Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where
    n_samples in the number of samples and n_features is the number of features.

Returns
self  [object] Returns the instance itself.

**fit_transform** *(X, y=None, **params)*
Fit the model from data in X and transform X.

Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where
    n_samples in the number of samples and n_features is the number of features.

Returns
X_new  [ndarray of shape (n_samples, n_components)]

**get_params** *(deep=True)*
Get parameters for this estimator.

Parameters
deep  [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

Returns
params  [dict] Parameter names mapped to their values.

**inverse_transform** *(X)*
Transform X back to original space.

Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_components)]

Returns
X_new  [ndarray of shape (n_samples, n_features)]

References

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters
**params  [dict] Estimator parameters.

Returns
self  [estimator instance] Estimator instance.

**transform** *(X)*
Transform X.
Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)]

Returns

X_new  [ndarray of shape (n_samples, n_components)]

Examples using sklearn.decomposition.KernelPCA

• Kernel PCA

7.8.6 sklearn.decomposition.LatentDirichletAllocation

class sklearn.decomposition.LatentDirichletAllocation(**kwargs)

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the User Guide.

Parameters

n_components  [int, default=10] Number of topics.

Changed in version 0.19: n_topics was renamed to n_components

doc_topic_prior  [float, default=None] Prior of document topic distribution theta. If the value
is None, defaults to 1 / n_components. In [1], this is called alpha.

topic_word_prior  [float, default=None] Prior of topic word distribution beta. If the value is
None, defaults to 1 / n_components. In [1], this is called eta.

learning_method  [['batch', 'online'], default='batch'] Method used to update _component.

Only used in fit method. In general, if the data size is large, the online update will be much
faster than the batch update.

Valid options:

'batch': Batch variational Bayes method. Use all training data in
each EM update.

Old `components_` will be overwritten in each iteration.

'online': Online variational Bayes method. In each EM update, use
mini-batch of training data to update the `components_`
variable incrementally. The learning rate is controlled by the
``learning_decay`` and the `learning_offset` parameters.

Changed in version 0.20: The default learning method is now "batch".

learning_decay  [float, default=0.7] It is a parameter that control learning rate in the online
learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic con-
vergence. When the value is 0.0 and batch_size is n_samples, the update method is same
as batch learning. In the literature, this is called kappa.

learning_offset  [float, default=10.] A (positive) parameter that downweights early iterations in
online learning. It should be greater than 1.0. In the literature, this is called tau_0.

max_iter  [int, default=10] The maximum number of iterations.

batch_size  [int, default=128] Number of documents to use in each EM iteration. Only used in
online learning.
evaluate_every  [int, default=0] How often to evaluate perplexity. Only used in fit method. Set it to 0 or negative number to not evaluate perplexity in training at all. Evaluating perplexity can help you check convergence in training process, but it will also increase total training time. Evaluating perplexity in every iteration might increase training time up to two-fold.

total_samples  [int, default=1e6] Total number of documents. Only used in the partial_fit method.

perp_tol  [float, default=1e-1] Perplexity tolerance in batch learning. Only used when evaluate_every is greater than 0.

n_jobs  [int, default=None] The number of jobs to use in the E-step. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose  [int, default=0] Verbosity level.

random_state  [int, RandomState instance or None, default=None] Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes

components_  [ndarray of shape (n_components, n_features)] Variational parameters for topic word distribution. Since the complete conditional for topic word distribution is a Dirichlet, components_[i, j] can be viewed as pseudocount that represents the number of times word j was assigned to topic i. It can also be viewed as distribution over the words for each topic after normalization: model.components_ / model.components_.sum(axis=1)[, np.newaxis].

exp_dirichlet_component_  [ndarray of shape (n_components, n_features)] Exponential value of expectation of log topic word distribution. In the literature, this is exp(E[log(beta)]).

n_batch_iter_  [int] Number of iterations of the EM step.

n_iter_  [int] Number of passes over the dataset.

bound_  [float] Final perplexity score on training set.

doc_topic_prior_  [float] Prior of document topic distribution theta. If the value is None, it is 1 / n_components.

random_state_  [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by np.random.

topic_word_prior_  [float] Prior of topic word distribution beta. If the value is None, it is 1 / n_components.
References

Examples

```python
>>> from sklearn.decomposition import LatentDirichletAllocation
>>> from sklearn.datasets import make_multilabel_classification

# This produces a feature matrix of token counts, similar to what
# CountVectorizer would produce on text.
>>> X, _ = make_multilabel_classification(random_state=0)

>>> lda = LatentDirichletAllocation(n_components=5,
                        random_state=0)
>>> lda.fit(X)
LatentDirichletAllocation(...)

>>> lda.transform(X[-2:])
array([[0.00360392, 0.25499205, 0.0036211 , 0.64236448, 0.09541846],
       [0.15297572, 0.00362644, 0.44412786, 0.39568399, 0.003586 ]])
```

**fit** *(X, y=None)*

Learn model for the data X with variational Bayes method.

When `learning_method` is ‘online’, use mini-batch update. Otherwise, use batch update.

**Parameters**

- **X** : array-like or sparse matrix of shape (n_samples, n_features)
  Document word matrix.
- **y** : ignored

**Returns**

- **self**

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Input samples.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

- X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

**partial_fit**(X, y=None)

Online VB with Mini-Batch update.

**Parameters**

- X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.
- y [Ignored]

**Returns**

- self

**perplexity**(X, sub_sampling=False)

Calculate approximate perplexity for data X.

Perplexity is defined as exp(-1. * log-likelihood per word)

Changed in version 0.19: doc_topic_distr argument has been deprecated and is ignored because user no longer has access to unnormalized distribution.

**Parameters**

- X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.
- sub_sampling [bool] Do sub-sampling or not.

**Returns**

- score [float] Perplexity score.

**score**(X, y=None)

Calculate approximate log-likelihood as score.

**Parameters**

- X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.
- y [Ignored]

**Returns**
score [float] Use approximate bound as score.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Transform data X according to the fitted model.

Changed in version 0.18: doc_topic_distr is now normalized

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Document word matrix.

Returns

doc_topic_distr [ndarray of shape (n_samples, n_components)] Document topic distribution for X.

Examples using sklearn.decomposition.LatentDirichletAllocation

- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation

7.8.7 sklearn.decomposition.MiniBatchDictionaryLearning

class sklearn.decomposition.MiniBatchDictionaryLearning(**kwargs)
Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

\[
(U^*, V^*) = \text{argmin} \ 0.5 \ || \ X - U \ V \ ||_2^2 + \alpha \ || \ U \ ||_1
\]

with \ || \ V_k \ ||_2 = 1 \ \text{for all} \ \ 0 \leq k < n\_components

Read more in the User Guide.

Parameters

n_components [int, default=None] Number of dictionary elements to extract.
alpha [float, default=1] Sparsity controlling parameter.
n_iter [int, default=1000] Total number of iterations to perform.
fit_algorithm [{‘lars’, ‘cd’}, default=’lars’] The algorithm used:
• 'lars': uses the least angle regression method to solve the lasso problem
(linear_model.lars_path)
• 'cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

**n_jobs** [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**batch_size** [int, default=3] Number of samples in each mini-batch.

**shuffle** [bool, default=True] Whether to shuffle the samples before forming batches.

**dict_init** [ndarray of shape (n_components, n_features), default=None] initial value of the dictionary for warm restart scenarios

**transform_algorithm** [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='omp'] Algorithm used to transform the data:
  • 'lars': uses the least angle regression method (linear_model.lars_path);
  • 'lasso_lars': uses Lars to compute the Lasso solution.
  • 'lasso_cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). 'lasso_lars' will be faster if the estimated components are sparse.
  • 'omp': uses orthogonal matching pursuit to estimate the sparse solution.
  • 'threshold': squashes to zero all coefficients less than alpha from the projection dictionary * X'.

**transform_n_nonzero_coefs** [int, default=None] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case. If None, then transform_n_nonzero_coefs=int(n_features / 10).

**transform_alpha** [float, default=None] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs if None, default to 1.

**verbose** [bool, default=False] To control the verbosity of the procedure.

**split_sign** [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**random_state** [int, RandomState instance or None, default=None] Used for initializing the dictionary when dict_init is not specified, randomly shuffling the data when shuffle is set to True, and updating the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.

**positive_code** [bool, default=False] Whether to enforce positivity when finding the code.

  New in version 0.20.

**positive_dict** [bool, default=False] Whether to enforce positivity when finding the dictionary.

  New in version 0.20.

**transform_max_iter** [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or 'lasso_lars'.

1820 Chapter 7. API Reference
New in version 0.22.

Attributes

components_ [ndarray of shape (n_components, n_features)] Components extracted from the data.

inner_stats_ [tuple of (A, B) ndarrays] Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid losing the history of the evolution, but they shouldn't have any use for the end user. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix.

n_iter_ [int] Number of iterations run.

iter_offset_ [int] The number of iteration on data batches that has been performed before.

random_state_ [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by np.random.

MiniBatchSparsePCA

Notes

References:

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_sparse_coded_signal
>>> from sklearn.decomposition import MiniBatchDictionaryLearning

>>> X, dictionary, code = make_sparse_coded_signal(n_samples=100, n_components=15, n_features=20, n_nonzero_coefs=10, random_state=42)
>>> dict_learner = MiniBatchDictionaryLearning(n_components=15, transform_algorithm='lasso_lars', random_state=42)
>>> X_transformed = dict_learner.fit_transform(X)

We can check the level of sparsity of X_transformed:

```python
>>> np.mean(X_transformed == 0)
0.87...
```

We can compare the average squared euclidean norm of the reconstruction error of the sparse coded signal relative to the squared euclidean norm of the original signal:

```python
```python
>>> X_hat = X_transformed @ dict_learner.components_
>>> np.mean(np.sum((X_hat - X) ** 2, axis=1) / np.sum(X ** 2, axis=1))
0.10...
```

**Methods**

- `fit(X[, y])` Fit the model from data in X.
- `fit_transform(X[, y])` Fit to data, then transform it.
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X[, y, iter_offset])` Updates the model using the data in X as a mini-batch.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Encode the data as a sparse combination of the dictionary atoms.

**fit** *(X, y=None)*

Fit the model from data in X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- `y` [Ignored]

**Returns**

- `self` [object] Returns the instance itself.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.
**partial_fit** *(X, y=None, iter_offset=None)*
Updates the model using the data in X as a mini-batch.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored]
- **iter_offset** [int, default=None] The number of iteration on data batches that has been performed before this call to partial_fit. This is optional: if no number is passed, the memory of the object is used.

**Returns**

- **self** [object] Returns the instance itself.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** *(X)*
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

- **X_new** [ndarray of shape (n_samples, n_components)] Transformed data.

**Examples using sklearn.decomposition.MiniBatchDictionaryLearning**

- *Image denoising using dictionary learning*
- *Faces dataset decompositions*
7.8.8 sklearn.decomposition.MiniBatchSparsePCA

```python
class sklearn.decomposition.MiniBatchSparsePCA(**kwargs)

    Mini-batch Sparse Principal Components Analysis

    Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is contro-
    lled by the coefficient of the L1 penalty, given by the parameter alpha.

    Read more in the User Guide.

    Parameters

    n_components [int, default=None] number of sparse atoms to extract
    alpha [int, default=1] Sparsity controlling parameter. Higher values lead to sparser compo-
        nents.
    ridge_alpha [float, default=0.01] Amount of ridge shrinkage to apply in order to improve con-
        ditioning when calling the transform method.
    n_iter [int, default=100] number of iterations to perform for each mini batch
    callback [callable, default=None] callable that gets invoked every five iterations
    batch_size [int, default=3] the number of features to take in each mini batch
    verbose [int or bool, default=False] Controls the verbosity; the higher, the more messages.
        Defaults to 0.
    shuffle [bool, default=True] whether to shuffle the data before splitting it in batches
    n_jobs [int, default=None] Number of parallel jobs to run. None means 1 unless in a
        joblib.parallel_backend context. -1 means using all processors. See Glossary
        for more details.
    method [{'lars', 'cd'}, default='lars'] lars: uses the least angle regression method to solve the
        lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute
        the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are
        sparse.
    random_state [int, RandomState instance or None, default=None] Used for random shuffling
        when shuffle is set to True, during online dictionary learning. Pass an int for repro-
        ducible results across multiple function calls. See Glossary.

    Attributes

    components_ [ndarray of shape (n_components, n_features)] Sparse components extracted
        from the data.
    n_components_ [int] Estimated number of components.
        New in version 0.23.
    n_iter_ [int] Number of iterations run.
    mean_ [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training
        set. Equal to X.mean(axis=0).

    See also:

    PCA
    SparsePCA
    DictionaryLearning
```
Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import MiniBatchSparsePCA

>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = MiniBatchSparsePCA(n_components=5, batch_size=50,
...   random_state=0)

>>> transformer.fit(X)
MiniBatchSparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
>>> np.mean(transformer.components_ == 0)
0.94
```

Methods

```python
fit(X[, y]) Fit the model from data in X.

fit_transform(X[, y], **fit_params) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

set_params(**params) Set the parameters of this estimator.

transform(X) Least Squares projection of the data onto the sparse components.
```

**fit (X, y=None)**

Fit the model from data in X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- `y` [Ignored]

**Returns**

- `self` [object] Returns the instance itself.

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.
**get_params** *(**deep**=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** *(X)*

Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the `ridge_alpha` parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

- **X_new** [ndarray of shape (n_samples, n_components)] Transformed data.

### 7.8.9 sklearn.decomposition.NMF

**class** `sklearn.decomposition.NMF(**kwargs)`

Non-Negative Matrix Factorization (NMF).

Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:
Where:
\[
\|A\|_F^2 = \sum_{i,j} A_{ij}^2 \quad \text{(Frobenius norm)}
\]
\[
\|\text{vec}(A)\|_1 = \sum_{i,j} \text{abs}(A_{ij}) \quad \text{(Elementwise L1 norm)}
\]

For multiplicative-update (‘mu’) solver, the Frobenius norm (0.5 * ||X - WH||^2_F) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H.

Read more in the User Guide.

**Parameters**

- **n_components** [int, default=None] Number of components, if n_components is not set all features are kept.

- **init** ['random', 'nndsvd', 'nndsvda', 'nndsvdar', 'custom'], default=None] Method used to initialize the procedure. Default: None. Valid options:
  - None: ‘nndsvd’ if n_components <= min(n_samples, n_features), otherwise random.
  - ‘random’: non-negative random matrices, scaled with: sqrt(X.mean() / n_components)
  - ‘nndsvd’: Nonnegative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
  - ‘nndsvda’: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
  - ‘nndsvdar’: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
  - ‘custom’: use custom matrices W and H

- **solver** ['cd', ‘mu’], default=’cd’] Numerical solver to use: ‘cd’ is a Coordinate Descent solver. ‘mu’ is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

- **beta_loss** [float or {'frobenius', 'kullback-leibler', 'itakura-saito'}, default='frobenius'] Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

- **tol** [float, default=1e-4] Tolerance of the stopping condition.

- **max_iter** [int, default=200] Maximum number of iterations before timing out.
random_state [int, RandomState instance or None, default=None] Used for initialisation (when init == 'nndsvdar' or 'random'), and in Coordinate Descent. Pass an int for reproducible results across multiple function calls. See Glossary.

alpha [float, default=0.] Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: alpha used in the Coordinate Descent solver.

l1_ratio [float, default=0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter l1_ratio used in the Coordinate Descent solver.

verbose [bool, default=False] Whether to be verbose.

shuffle [bool, default=False] If true, randomize the order of coordinates in the CD solver.

New in version 0.17: shuffle parameter used in the Coordinate Descent solver.

regularization [{'both', 'components', 'transformation', None}, default='both'] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

New in version 0.24.

Attributes

components_ [ndarray of shape (n_components, n_features)] Factorization matrix, sometimes called ‘dictionary’.

n_components_ [int] The number of components. It is same as the n_components parameter if it was given. Otherwise, it will be same as the number of features.

reconstruction_err_ [float] Frobenius norm of the matrix difference, or beta-divergence, between the training data X and the reconstructed data WH from the fitted model.

n_iter_ [int] Actual number of iterations.

References

Examples

```python
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_
```

Methods

<td>Transform the data X according to the fitted NMF model.</td>
</tr>
</tbody>
</table>

**fit** *(X, y=None, **params)*

Learn a NMF model for the data X.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Data matrix to be decomposed
- **y** [Ignored]

**Returns**

self

**fit_transform** *(X, y=None, W=None, H=None)*

Learn a NMF model for the data X and returns the transformed data.

This is more efficient than calling fit followed by transform.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Data matrix to be decomposed
- **y** [Ignored]
- **W** [array-like of shape (n_samples, n_components)] If init='custom', it is used as initial guess for the solution.
- **H** [array-like of shape (n_components, n_features)] If init='custom', it is used as initial guess for the solution.

**Returns**

**W** [ndarray of shape (n_samples, n_components)] Transformed data.

get_params *(deep=True)*

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (W)

Transform data back to its original space.

Parameters

W [{ndarray, sparse matrix} of shape (n_samples, n_components)] Transformed data matrix.

Returns

X [{ndarray, sparse matrix} of shape (n_samples, n_features)] Data matrix of original shape.

New in version 0.18: ..

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Transform the data X according to the fitted NMF model.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Data matrix to be transformed by the model.

Returns

W [ndarray of shape (n_samples, n_components)] Transformed data.

Examples using sklearn.decomposition.NMF

- Beta-divergence loss functions
- Faces dataset decompositions
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Selecting dimensionality reduction with Pipeline and GridSearchCV
Principal component analysis (PCA).

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the scipy.sparse.linalg ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See TruncatedSVD for an alternative with sparse data.

Read more in the User Guide.

Parameters

**n_components** [int, float or str, default=None] Number of components to keep. if n_components is not set all components are kept:

\[
\text{n\_components} = \min(\text{n\_samples, n\_features})
\]

If n_components == 'mle' and svd_solver == 'full', Minka's MLE is used to guess the dimension. Use of n_components == 'mle' will interpret svd_solver == 'auto' as svd_solver == 'full'.

If 0 < n_components < 1 and svd_solver == 'full', select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by n_components.

If svd_solver == 'arpack', the number of components must be strictly less than the minimum of n_features and n_samples.

Hence, the None case results in:

\[
\text{n\_components} = \min(\text{n\_samples, n\_features}) - 1
\]

**copy** [bool, default=True] If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

**whiten** [bool, default=False] When True (False by default) the components_vectors are multiplied by the square root of n_samples and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the down-stream estimators by making their data respect some hard-wired assumptions.

**svd_solver** [‘auto’, ‘full’, ‘arpack’, ‘randomized’], default=’auto’

If auto: The solver is selected by a default policy based on X.shape and n_components: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient ‘randomized’ method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.

If full: run exact full SVD calling the standard LAPACK solver via scipy.linalg.svd and select the components by postprocessing.
If **arpack** : run SVD truncated to n_components calling ARPACK solver via \texttt{scipy.sparse.linalg.svds}. It requires strictly 0 < n_components < min(X.shape)

If **randomized** : run randomized SVD by the method of Halko et al.

New in version 0.18.0.

**tol** [float, default=0.0] Tolerance for singular values computed by svd_solver == ‘arpack’. Must be of range [0.0, infinity).

New in version 0.18.0.

**iterated_power** [int or ‘auto’, default=’auto’] Number of iterations for the power method computed by svd_solver == ‘randomized’. Must be of range [0, infinity).

New in version 0.18.0.

**random_state** [int, RandomState instance or None, default=None] Used when the ‘arpack’ or ‘randomized’ solvers are used. Pass an int for reproducible results across multiple function calls. See \textit{Glossary}.

New in version 0.18.0.

**Attributes**

**components_** [ndarray of shape (n_components, n_features)] Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by explained_variance_.

**explained_variance_** [ndarray of shape (n_components,)] The amount of variance explained by each of the selected components.

Equal to n_components largest eigenvalues of the covariance matrix of X.

New in version 0.18.

**explained_variance_ratio_** [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components.

If n_components is not set then all components are stored and the sum of the ratios is equal to 1.0.

**singular_values_** [ndarray of shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

New in version 0.19.

**mean_** [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training set.

Equal to X.mean(axis=0).

**n_components_** [int] The estimated number of components. When n_components is set to ‘mle’ or a number between 0 and 1 (with svd_solver == ‘full’) this number is estimated from input data. Otherwise it equals the parameter n_components, or the lesser value of n_features and n_samples if n_components is None.

**n_features_** [int] Number of features in the training data.

**n_samples_** [int] Number of samples in the training data.

**noise_variance_** [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See “Pattern Recognition and Machine Learning” by C.
Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf. It is required to compute the estimated data covariance and score samples.

Equal to the average of (min(n_features, n_samples) - n_components) smallest eigenvalues of the covariance matrix of X.

**KernelPCA** Kernel Principal Component Analysis.

**SparsePCA** Sparse Principal Component Analysis.

**TruncatedSVD** Dimensionality reduction using truncated SVD.

**IncrementalPCA** Incremental Principal Component Analysis.

References

For n_components == ‘mle’, this class uses the method of Minka, T. P. “Automatic choice of dimensionality for PCA”. In NIPS, pp. 598-604

For svd_solver == ‘arpack’, refer to scipy.sparse.linalg.svds.

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import PCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> pca = PCA(n_components=2)
>>> pca.fit(X)
PCA(n_components=2)
>>> print(pca.explained_variance_ratio_)
[0.9924... 0.0075...]
>>> print(pca.singular_values_)
[6.30061... 0.54980...]
>>> pca = PCA(n_components=1, svd_solver='arpack')
>>> pca.fit(X)
```
PCA(n_components=1, svd_solver='arpack')

```python
>>> print(pca.explained_variance_ratio_)
[0.99244...]
>>> print(pca.singular_values_)
[6.30061...]
```

## Methods

- `fit(X[, y])`: Fit the model with X.
- `fit_transform(X[, y])`: Fit the model with X and apply the dimensionality reduction on X.
- `get_covariance()`: Compute data covariance with the generative model.
- `get_params([deep])`: Get parameters for this estimator.
- `get_precision()`: Compute data precision matrix with the generative model.
- `inverse_transform(X)`: Transform data back to its original space.
- `score(X[, y])`: Return the average log-likelihood of all samples.
- `score_samples(X)`: Return the log-likelihood of each sample.
- `set_params(**params)`: Set the parameters of this estimator.
- `transform(X)`: Apply dimensionality reduction to X.

### fit(X, y=None)

Fit the model with X.

**Parameters**

- **X**: array-like of shape (n_samples, n_features) – Training data, where n_samples is the number of samples and n_features is the number of features.
- **y**: [Ignored]

**Returns**

- **self**: [object] – Returns the instance itself.

### fit_transform(X, y=None)

Fit the model with X and apply the dimensionality reduction on X.

**Parameters**

- **X**: array-like of shape (n_samples, n_features) – Training data, where n_samples is the number of samples and n_features is the number of features.
- **y**: [Ignored]

**Returns**

- **X_new**: [ndarray of shape (n_samples, n_components)] – Transformed values.
Notes

This method returns a Fortran-ordered array. To convert it to a C-ordered array, use `np.ascontiguousarray`.

**get_covariance()**

Compute data covariance with the generative model.

\[
\text{cov} = \text{components}_-^\top \ast S^2 \ast \text{components}_+ + \sigma^2 \ast \text{eye}(n\text{features})
\]

where \(S^2\) contains the explained variances, and \(\sigma^2\) contains the noise variances.

**Returns**

- **cov** [array, shape=(n_features, n_features)] Estimated covariance of data.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**get_precision()**

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

**Returns**

- **precision** [array, shape=(n_features, n_features)] Estimated precision of data.

**inverse_transform**(X)

Transform data back to its original space.

In other words, return an input \(X\_\text{original}\) whose transform would be \(X\).

**Parameters**

- **X** [array-like, shape (n_samples, n_components)] New data, where \(n\text{samples}\) is the number of samples and \(n\text{components}\) is the number of components.

**Returns**

- **X\_original** array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

**score**(X, y=None)

Return the average log-likelihood of all samples.

See “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data.
- **y** [Ignored]

---

7.8. sklearn.decomposition: Matrix Decomposition
Returns

- **ll** [float] Average log-likelihood of the samples under the current model.

**score_samples** *(X)*

Return the log-likelihood of each sample.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data.

**Returns**

- **ll** [ndarray of shape (n_samples,)] Log-likelihood of each sample under the current model.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** *(X)*

Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **X_new** [array-like, shape (n_samples, n_components)]

**Examples**

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X)
```
Examples using `sklearn.decomposition.PCA`

- A demo of K-Means clustering on the handwritten digits data
- Principal Component Regression vs Partial Least Squares Regression
- The Iris Dataset
- PCA example with Iris Data-set
- Incremental PCA
- Comparison of LDA and PCA 2D projection of Iris dataset
- Factor Analysis (with rotation) to visualize patterns
- Blind source separation using FastICA
- Principal components analysis (PCA)
- FastICA on 2D point clouds
- Kernel PCA
- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Faces dataset decompositions
- Faces recognition example using eigenfaces and SVMs
- Multi-dimensional scaling
- Multilabel classification
- Explicit feature map approximation for RBF kernels
- Balance model complexity and cross-validated score
- Kernel Density Estimation
- Dimensionality Reduction with Neighborhood Components Analysis
- Concatenating multiple feature extraction methods
- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Importance of Feature Scaling

**7.8.11 `sklearn.decomposition.SparsePCA`**

The `SparsePCA` class is used to find a set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

```python
class sklearn.decomposition.SparsePCA(**kwargs)
```

Sparse Principal Components Analysis (SparsePCA).

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

**Parameters**

- `n_components` [int, default=None] Number of sparse atoms to extract.
- `alpha` [float, default=1] Sparsity controlling parameter. Higher values lead to sparser components.
**ridge_alpha**  [float, default=0.01] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.

**max_iter**  [int, default=1000] Maximum number of iterations to perform.

**tol**  [float, default=1e-8] Tolerance for the stopping condition.

**method**  [['lars', 'cd'], default='lars'] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

**n_jobs**  [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**U_init**  [ndarray of shape (n_samples, n_components), default=None] Initial values for the loadings for warm restart scenarios.

**V_init**  [ndarray of shape (n_components, n_features), default=None] Initial values for the components for warm restart scenarios.

**verbose**  [int or bool, default=False] Controls the verbosity; the higher, the more messages. Defaults to 0.

**random_state**  [int, RandomState instance or None, default=None] Used during dictionary learning. Pass an int for reproducible results across multiple function calls. See Glossary.

**Attributes**

- **components_**  [ndarray of shape (n_components, n_features)] Sparse components extracted from the data.

- **error_**  [ndarray] Vector of errors at each iteration.

- **n_components_**  [int] Estimated number of components.

  New in version 0.23.

- **n_iter_**  [int] Number of iterations run.

- **mean_**  [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to X.mean(axis=0).

**See also:**

- **PCA**
- **MiniBatchSparsePCA**
- **DictionaryLearning**

**Examples**

```python
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import SparsePCA
>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = SparsePCA(n_components=5, random_state=0)
>>> transformer.fit(X)
SparsePCA(...)
>>> X_transformed = transformer.transform(X)
```

(continues on next page)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
>>> np.mean(transformer.components_ == 0)
0.9666...

## Methods

### fit (X, y=None)

Fit the model from data in X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored]

**Returns**

- **self** [object] Returns the instance itself.

### fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.
set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the ridge_alpha parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters

X [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [ndarray of shape (n_samples, n_components)] Transformed data.

7.8.12 sklearn.decomposition.SparseCoder
class sklearn.decomposition.SparseCoder(**kwargs)
Sparse coding
Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array code such that:

\[
X \approx \text{code} \times \text{dictionary}
\]

Read more in the User Guide.

Parameters

dictionary [ndarray of shape (n_components, n_features)] The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.

transform_algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='omp']
Algorithm used to transform the data:

- 'lars': uses the least angle regression method (linear_model.lars_path);
- 'lasso_lars': uses Lars to compute the Lasso solution;
- 'lasso_cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). 'lasso_lars' will be faster if the estimated components are sparse;
- 'omp': uses orthogonal matching pursuit to estimate the sparse solution;
• 'threshold': squashes to zero all coefficients less than alpha from the projection
dictionary * X'.

transform_n_nonzero_coefs [int, default=None] Number of nonzero coefficients to target
in each column of the solution. This is only used by algorithm='lars' and
algorithm='omp' and is overridden by alpha in the omp case. If None, then
transform_n_nonzero_coefs=int(n_features / 10).

transform_alpha [float, default=None] If algorithm='lasso_lars' or
algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If
algorithm='threshold', alpha is the absolute value of the threshold below
which coefficients will be squashed to zero. If algorithm='omp', alpha is the
tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides
n_nonzero_coefs. If None, default to 1.

split_sign [bool, default=False] Whether to split the sparse feature vector into the concatenation
of its negative part and its positive part. This can improve the performance of downstream
classifiers.

n_jobs [int, default=None] Number of parallel jobs to run. None means 1 unless in a
joblib.parallel_backend context. -1 means using all processors. See Glossary
for more details.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.
New in version 0.20.

transform_max_iter [int, default=1000] Maximum number of iterations to perform if
algorithm='lasso_cd' or lasso_lars.
New in version 0.22.

Attributes

components_ [ndarray of shape (n_components, n_features)] The unchanged dictionary atoms.
Deprecate since version 0.24: This attribute is deprecated in 0.24 and will be removed in
0.26. Use dictionary instead.

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import SparseCoder
>>> X = np.array([[-1, -1, -1], [0, 0, 3]])
>>> dictionary = np.array(
...     [[0, 1, 0],
...      [-1, -1, 2],
...      [1, 1, 1],
...      [0, 1, 1],
```

(continues on next page)
...    [0, 2, 1]),
...    dtype=np.float64
...)
>>> coder = SparseCoder(
...    dictionary=dictionary, transform_algorithm='lasso_lars',
...    transform_alpha=1e-10,
...)
>>> coder.transform(X)
array([[ 0.,  0., -1.,  0.,  0.],
       [ 0.,  1.,  1.,  0.,  0.]])

**fit** (X, y=None)

Do nothing and return the estimator unchanged.

This method is just there to implement the usual API and hence work in pipelines.

Parameters

- **X** [Ignored]
- **y** [Ignored]

Returns

- **self** [object]

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters **fit_params** and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X, y=None)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter transform_algorithm.

Parameters

X [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the
same number of features as the data used to train the model.

Returns

X_new [ndarray of shape (n_samples, n_components)] Transformed data.

Examples using sklearn.decomposition.SparseCoder

• Sparse coding with a precomputed dictionary

7.8.13 sklearn.decomposition.TruncatedSVD
class sklearn.decomposition.TruncatedSVD(**kwargs)
Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition
(SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decom-
position. This means it can work with sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in sklearn.
feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a “naive” algorithm that uses
ARPACK as an eigensolver on X * X.T or X.T * X, whichever is more efficient.

Read more in the User Guide.

Parameters

n_components [int, default=2] Desired dimensionality of output data. Must be strictly less than
the number of features. The default value is useful for visualisation. For LSA, a value of
100 is recommended.
algorithm [{‘arpack’, ‘randomized’}, default=’randomized’] SVD solver to use. Either “arpack” for the ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or “randomized” for the randomized algorithm due to Halko (2009).

n_iter [int, default=5] Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in randomized_svd to handle sparse matrices that may have large slowly decaying spectrum.

random_state [int, RandomState instance or None, default=None] Used during randomized svd. Pass an int for reproducible results across multiple function calls. See Glossary.

tol [float, default=0.] Tolerance for ARPACK. 0 means machine precision. Ignored by randomized SVD solver.

Attributes

components_ [ndarray of shape (n_components, n_features)]

explained_variance_ [ndarray of shape (n_components,)] The variance of the training samples transformed by a projection to each component.

explained_variance_ratio_ [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components.

singular_values_ [ndarray of shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

See also:

PCA

Notes

SVD suffers from a problem called “sign indeterminacy”, which means the sign of the components_ and the output from transform depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

#### `fit `(X, y=None)

Fit model on training data X.

**Parameters**

- **X**  
  [array-like, sparse matrix] of shape (n_samples, n_features) Training data.  
- **y**  
  [Ignored]

**Returns**

- **self**  
  [object] Returns the transformer object.

#### `fit_transform `(X, y=None)

Fit model to X and perform dimensionality reduction on X.

**Parameters**

- **X**  
  [array-like, sparse matrix] of shape (n_samples, n_features) Training data.  
- **y**  
  [Ignored]

**Returns**

- **X_new**  
  [ndarray of shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

#### `get_params`(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep**  
  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**  
  [dict] Parameter names mapped to their values.

#### `inverse_transform `(X)

Transform X back to its original space.

Returns an array X_original whose transform would be X.

**Parameters**

- **X**  
  [array-like of shape (n_samples, n_components)] New data.
Returns

X_original [ndarray of shape (n_samples, n_features)] Note that this is always a dense array.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Perform dimensionality reduction on X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data.

Returns

X_new [ndarray of shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

Examples using sklearn.decomposition.TruncatedSVD

• Hashing feature transformation using Totally Random Trees
• Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
• Column Transformer with Heterogeneous Data Sources
• Clustering text documents using k-means

decomposition.dict_learning(X, n_components,...) Solves a dictionary learning matrix factorization problem.
decomposition.dict_learning_online(X,...) Solves a dictionary learning matrix factorization problem online.
decomposition.fastica(X,[n_components,...]) Perform Fast Independent Component Analysis.
decomposition.non_negative_factorization Compute Non-negative Matrix Factorization (NMF).
decomposition.sparse_encode(X,dictionary,...) Sparse coding

1846 Chapter 7. API Reference
Solves a dictionary learning matrix factorization problem.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix `X` by solving:

\[(U^*, V^*) = \underset{U, V}{\arg\min} \frac{1}{2} \| X - U V \|^2_2 + \alpha \| U \|_1 \]

where `V` is the dictionary and `U` is the sparse code.

Read more in the User Guide.

Parameters

- `X` [ndarray of shape (n_samples, n_features)] Data matrix.
- `n_components` [int] Number of dictionary atoms to extract.
- `alpha` [int] Sparsity controlling parameter.
- `max_iter` [int, default=100] Maximum number of iterations to perform.
- `tol` [float, default=1e-8] Tolerance for the stopping condition.
- `method` [{`'lars'`, `'cd'`}, default=`'lars'`] The method used:
  - `'lars'`: uses the least angle regression method to solve the lasso problem
    (linear_model.lars_path);
  - `'cd'`: uses the coordinate descent method to compute the Lasso solution
    (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- `n_jobs` [int, default=None] Number of parallel jobs to run. `None` means 1 unless in a joblib.parallel_backend context. `-1` means using all processors. See Glossary for more details.
- `dict_init` [ndarray of shape (n_components, n_features), default=None] Initial value for the dictionary for warm restart scenarios.
- `code_init` [ndarray of shape (n_samples, n_components), default=None] Initial value for the sparse code for warm restart scenarios.
- `callback` [callable, default=None] Callable that gets invoked every five iterations
- `verbose` [bool, default=False] To control the verbosity of the procedure.
- `random_state` [int, RandomState instance or None, default=None] Used for randomly initializing the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.
- `return_n_iter` [bool, default=False] Whether or not to return the number of iterations.
- `positive_dict` [bool, default=False] Whether to enforce positivity when finding the dictionary.

New in version 0.20.
positive_code [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

method_max_iter [int, default=1000] Maximum number of iterations to perform.

New in version 0.22.

Returns

code [ndarray of shape (n_samples, n_components)] The sparse code factor in the matrix factorization.

dictionary [ndarray of shape (n_components, n_features),] The dictionary factor in the matrix factorization.

ersors [array] Vector of errors at each iteration.

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

SparsePCA
MiniBatchSparsePCA

7.8.15 sklearn.decomposition.dict_learning_online

Solves a dictionary learning matrix factorization problem online. Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

\[(U^*, V^*) = \arg\min_{U, V} \frac{1}{2} \| X - UV \|_2^2 + \alpha \| U \|_1 \]

\[(U, V)\]

with \( \| V_k \|_2 = 1 \) for all \( 0 \leq k < n_{\text{components}} \)

where V is the dictionary and U is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples, n_features)] Data matrix.

n_components [int, default=2] Number of dictionary atoms to extract.

alpha [float, default=1] Sparsity controlling parameter.
n_iter [int, default=100] Number of mini-batch iterations to perform.

return_code [bool, default=True] Whether to also return the code U or just the dictionary V.

dict_init [ndarray of shape (n_components, n_features), default=None] Initial value for the dictionary for warm restart scenarios.

callback [callable, default=None] Callable that gets invoked every five iterations.

batch_size [int, default=3] The number of samples to take in each batch.

verbose [bool, default=False] To control the verbosity of the procedure.

shuffle [bool, default=True] Whether to shuffle the data before splitting it in batches.

n_jobs [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

method [{‘lars’, ‘cd’}, default=’lars’]

• ‘lars’: uses the least angle regression method to solve the lasso problem (linear_model.lars_path);

• ‘cd’: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

iter_offset [int, default=0] Number of previous iterations completed on the dictionary used for initialization.

random_state [int, RandomState instance or None, default=None] Used for initializing the dictionary when dict_init is not specified, randomly shuffling the data when shuffle is set to True, and updating the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.

return_inner_stats [bool, default=False] Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If return_inner_stats is True, return_code is ignored.

inner_stats [tuple of (A, B) ndarrays, default=None] Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid losing the history of the evolution. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

positive_dict [bool, default=False] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

method_max_iter [int, default=1000] Maximum number of iterations to perform when solving the lasso problem.

New in version 0.22.

Returns

code [ndarray of shape (n_samples, n_components),] The sparse code (only returned if return_code=True).

dictionary [ndarray of shape (n_components, n_features),] The solutions to the dictionary learning problem.
**n_iter** [int] Number of iterations run. Returned only if *return_n_iter* is set to True.

See also:

### 7.8.16 sklearn.decomposition.fastica

**sklearn.decomposition.fastica** *(X, n_components=None, *, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None, return_X_mean=False, compute_sources=True, return_n_iter=False)*

Perform Fast Independent Component Analysis.

Read more in the User Guide.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **n_components** [int, default=None] Number of components to extract. If None no dimension reduction is performed.
- **algorithm** [{'parallel', 'deflation'}, default='parallel'] Apply a parallel or deflational FASTICA algorithm.
- **whiten** [bool, default=True] If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n_components will be ignored.
- **fun** [{'logcosh', 'exp', 'cube'} or callable, default='logcosh'] The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. The derivative should be averaged along its last dimension. Example:

  ```python
def my_g(x):
    return x ** 3, np.mean(3 * x ** 2, axis=-1)
```

- **fun_args** [dict, default=None] Arguments to send to the functional form. If empty or None and if fun=’logcosh’, fun_args will take value {'alpha': 1.0}
- **max_iter** [int, default=200] Maximum number of iterations to perform.
- **tol** [float, default=1e-04] A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.
- **w_init** [ndarray of shape (n_components, n_components), default=None] Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.’s is used.
- **random_state** [int, RandomState instance or None, default=None] Used to initialize w_init when not specified, with a normal distribution. Pass an int, for reproducible results across multiple function calls. See *Glossary*. 

---

1850 Chapter 7. API Reference
return_X_mean [bool, default=False] If True, X_mean is returned too.

compute_sources [bool, default=True] If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

Returns

K [ndarray of shape (n_components, n_features) or None] If whiten is ‘True’, K is the pre-whitening matrix that projects data onto the first n_components principal components. If whiten is ‘False’, K is ‘None’.

W [ndarray of shape (n_components, n_components)] The square matrix that unmixes the data after whitening. The mixing matrix is the pseudo-inverse of matrix \( W K \) if K is not None, else it is the inverse of W.

S [ndarray of shape (n_samples, n_components) or None] Estimated source matrix

X_mean [ndarray of shape (n_features,)] The mean over features. Returned only if return_X_mean is True.

n_iter [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return_n_iter is set to True.

Notes

The data matrix X is considered to be a linear combination of non-Gaussian (independent) components i.e. \( X = AS \) where columns of S contain the independent components and A is a linear mixing matrix. In short ICA attempts to un-mix’ the data by estimating an un-mixing matrix \( W \) where \( S = W K X \). While FastICA was proposed to estimate as many sources as features, it is possible to estimate less by setting n_components < n_features. It this case K is not a square matrix and the estimated A is the pseudo-inverse of \( W K \).

This implementation was originally made for data of shape [n_features, n_samples]. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

7.8.17 sklearn.decomposition.non_negative_factorization

sklearn.decomposition.non_negative_factorization(X, W=None, H=None, n_components=None, *, init=None, update_H=True, solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, alpha=0.0, l1_ratio=0.0, regularization=None, random_state=None, verbose=0, shuffle=False)

Compute Non-negative Matrix Factorization (NMF).

Find two non-negative matrices \( (W, H) \) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:
\[0.5 \times \|X - WH\|_{F_r}^2 + \alpha \times l_1 \text{ratio} \times \|\text{vec}(W)\|_1 + \alpha \times l_1 \text{ratio} \times \|\text{vec}(H)\|_1 + 0.5 \times \alpha \times (1 - l_1 \text{ratio}) \times \|W\|_{F_r}^2 + 0.5 \times \alpha \times (1 - l_1 \text{ratio}) \times \|H\|_{F_r}^2\]

Where:
\[\|A\|_{F_r}^2 = \sum_{i,j} A_{ij}^2\] (Frobenius norm)
\[\|\text{vec}(A)\|_1 = \sum_{i,j} \text{abs}(A_{ij})\] (Elementwise L1 norm)

For multiplicative-update (‘mu’) solver, the Frobenius norm \(0.5 \times \|X - WH\|_{F_r}^2\) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H. If H is given and update_H=False, it solves for W only.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Constant matrix.
- **W** [array-like of shape (n_samples, n_components), default=None] If init=’custom’, it is used as initial guess for the solution.
- **H** [array-like of shape (n_components, n_features), default=None] If init=’custom’, it is used as initial guess for the solution. If update_H=False, it is used as a constant, to solve for W only.
- **n_components** [int, default=None] Number of components, if n_components is not set all features are kept.
- **init** [{'random', 'nndsvd', 'nndsvda', 'nndsvdar', 'custom'}, default=None] Method used to initialize the procedure.

Valid options:
- None: ‘nndsvd’ if n_components < n_features, otherwise ‘random’.
- ‘random’: non-negative random matrices, scaled with: sqrt(X.mean() / n_components)
- ‘nndsvd’: Nonnegative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
- ‘nndsvda’: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
- ‘nndsvdar’: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
- ‘custom’: use custom matrices W and H if update_H=True. If update_H=False, then only custom matrix H is used.

Changed in version 0.23: The default value of init changed from ‘random’ to None in 0.23.

- **update_H** [bool, default=True] Set to True, both W and H will be estimated from initial guesses. Set to False, only W will be estimated.
- **solver** [{'cd', 'mu'}, default='cd'] Numerical solver to use:
• ‘cd’ is a Coordinate Descent solver that uses Fast Hierarchical Alternating Least Squares (Fast HALS).

• ‘mu’ is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

beta_loss [float or {'frobenius', 'kullback-leibler', 'itakura-saito'}, default='frobenius'] Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

max_iter [int, default=200] Maximum number of iterations before timing out.

alpha [float, default=0.] Constant that multiplies the regularization terms.

l1_ratio [float, default=0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

regularization [{‘both’, ‘components’, ‘transformation’}, default=None] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

random_state [int, RandomState instance or None, default=None] Used for NMF initialization (when init == ‘nndsvdar’ or ‘random’), and in Coordinate Descent. Pass an int for reproducible results across multiple function calls. See Glossary.

verbose [int, default=0] The verbosity level.

shuffle [bool, default=False] If true, randomize the order of coordinates in the CD solver.

Returns

W [ndarray of shape (n_samples, n_components)] Solution to the non-negative least squares problem.

H [ndarray of shape (n_components, n_features)] Solution to the non-negative least squares problem.

n_iter [int] Actual number of iterations.

References

Examples

```python
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import non_negative_factorization
>>> W, H, n_iter = non_negative_factorization(X, n_components=2, ...
               init='random', random_state=0)
```

7.8.18 sklearn.decomposition.sparse_encode

`sklearn.decomposition.sparse_encode(X, dictionary, *, gram=None, cov=None, algorithm='lasso_lars', n_nonzero_coefs=None, alpha=None, copy_cov=True, init=None, max_iter=1000, n_jobs=None, check_input=True, verbose=0, positive=False)`

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array `code` such that:

```
X ~= code * dictionary
```

Read more in the User Guide.

Parameters

- **X** [ndarray of shape (n_samples, n_features)] Data matrix.
- **dictionary** [ndarray of shape (n_components, n_features)] The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.
- **gram** [ndarray of shape (n_components, n_components), default=None] Precomputed Gram matrix, `dictionary * dictionary'`.
- **cov** [ndarray of shape (n_components, n_samples), default=None] Precomputed covariance, `dictionary' * X`.
- **algorithm** ['lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold', default='lasso_lars'] The algorithm used:
  - 'lasso_lars': uses the least angle regression method (`linear_model.lars_path`);
  - 'lasso_cd': uses Lars to compute the Lasso solution;
  - 'lasso_cd': uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). lasso_lars will be faster if the estimated components are sparse;
  - 'omp': uses orthogonal matching pursuit to estimate the sparse solution;
  - 'threshold': squashes to zero all coefficients less than regularization from the projection `dictionary * data`.
- **n_nonzero_coefs** [int, default=None] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lasso_lars'` and `algorithm='omp'` and is overridden by `alpha` in the `omp` case. If None, then `n_nonzero_coefs=int(n_features / 10)`.
alpha [float, default=None] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs. If None, default to 1.

copy_cov [bool, default=True] Whether to copy the precomputed covariance matrix; if False, it may be overwritten.

init [ndarray of shape (n_samples, n_components), default=None] Initialization value of the sparse codes. Only used if algorithm='lasso_cd'.

max_iter [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or 'lasso_lars'.

n_jobs [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

check_input [bool, default=True] If False, the input arrays X and dictionary will not be checked.

verbose [int, default=0] Controls the verbosity; the higher, the more messages.

positive [bool, default=False] Whether to enforce positivity when finding the encoding. New in version 0.20.

Returns
code [ndarray of shape (n_samples, n_components)] The sparse codes

Linear Discriminant Analysis

A classifier with a linear decision boundary, generated by fitting class conditional densities to the data and using Bayes’ rule.

The model fits a Gaussian density to each class, assuming that all classes share the same covariance matrix.

The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discriminative directions, using the `transform` method.

New in version 0.17: `LinearDiscriminantAnalysis`.

Read more in the User Guide.

Parameters

- **solver** [‘svd’, ‘lsqr’, ‘eigen’], default=’svd’
  
  **Solver to use, possible values:**

  - ‘svd’: Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
  
  - ‘lsqr’: Least squares solution. Can be combined with shrinkage or custom covariance estimator.
  
  - ‘eigen’: Eigenvalue decomposition. Can be combined with shrinkage or custom covariance estimator.

- **shrinkage** [‘auto’ or float, default=None]
  
  **Shrinkage parameter, possible values:**

  - None: no shrinkage (default).
  
  - ‘auto’: automatic shrinkage using the Ledoit-Wolf lemma.
  
  - float between 0 and 1: fixed shrinkage parameter.

  This should be left to None if `covariance_estimator` is used. Note that shrinkage works only with ‘lsqr’ and ‘eigen’ solvers.

- **priors** [array-like of shape (n_classes,), default=None] The class prior probabilities. By default, the class proportions are inferred from the training data.

- **n_components** [int, default=None] Number of components (<= min(n_classes - 1, n_features)) for dimensionality reduction. If None, will be set to min(n_classes - 1, n_features). This parameter only affects the `transform` method.

- **store_covariance** [bool, default=False] If True, explicitly compute the weighted within-class covariance matrix when solver is ‘svd’. The matrix is always computed and stored for the other solvers.

  New in version 0.17.
tol [float, default=1.0e-4] Absolute threshold for a singular value of X to be considered significant, used to estimate the rank of X. Dimensions whose singular values are non-significant are discarded. Only used if solver is ‘svd’.

New in version 0.17.

covariance_estimator [covariance estimator, default=None] If not None, covariance_estimator is used to estimate the covariance matrices instead of relying on the empirical covariance estimator (with potential shrinkage). The object should have a fit method and a covariance_attribute like the estimators in sklearn.covariance. If None the shrinkage parameter drives the estimate.

This should be left to None if shrinkage is used. Note that covariance_estimator works only with ‘lsqr’ and ‘eigen’ solvers.

New in version 0.24.

Attributes

coef_ [ndarray of shape (n_features,) or (n_classes, n_features)] Weight vector(s).

intercept_ [ndarray of shape (n_classes,)] Intercept term.

covariance_ [array-like of shape (n_features, n_features)] Weighted within-class covariance matrix. It corresponds to sum_k prior_k * C_k where C_k is the covariance matrix of the samples in class k. The C_k are estimated using the (potentially shrunk) biased estimator of covariance. If solver is ‘svd’, only exists when store_covariance is True.

explained_variance_ratio_ [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components. If n_components is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.

means_ [array-like of shape (n_classes, n_features)] Class-wise means.

priors_ [array-like of shape (n_classes,)] Class priors (sum to 1).

scalings_ [array-like of shape (rank, n_classes - 1)] Scaling of the features in the space spanned by the class centroids. Only available for ‘svd’ and ‘eigen’ solvers.

xbar_ [array-like of shape (n_features,)] Overall mean. Only present if solver is ‘svd’.

classes_ [array-like of shape (n_classes,)] Unique class labels.

QuadraticDiscriminantAnalysis Quadratic Discriminant Analysis.

Examples

```python
>>> import numpy as np
>>> from sklearn.discriminant_analysis import LinearDiscriminantAnalysis
>>> X = np.array([[1, 2], [2, 3], [3, 4], [4, 5], [5, 6]])
>>> y = np.array([1, 2, 3, 4, 5])
>>> clf = LinearDiscriminantAnalysis()
>>> clf.fit(X, y)
LinearDiscriminantAnalysis()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```
Methods

**decision_function**<br>
Apply decision function to an array of samples.

**fit**(X, y)<br>
Fit LinearDiscriminantAnalysis model according to the given training data and parameters.

**fit_transform**(X, y)<br>
Fit to data, then transform it.

**get_params**(deep)<br>
Get parameters for this estimator.

**predict**(X)<br>
Predict class labels for samples in X.

**predict_log_proba**(X)<br>
Estimate log probability.

**predict_proba**(X)<br>
Estimate probability.

**score**(X, y[, sample_weight])<br>
Return the mean accuracy on the given test data and labels.

**set_params**(**params)**<br>
Set the parameters of this estimator.

**transform**(X)<br>
Project data to maximize class separation.

---

**decision_function**<br>
Apply decision function to an array of samples.

The decision function is equal (up to a constant factor) to the log-posterior of the model, i.e. \( \log p(y = k | x) \). In a binary classification setting this instead corresponds to the difference \( \log p(y = 1 | x) - \log p(y = 0 | x) \). See Mathematical formulation of the LDA and QDA classifiers.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

**Returns**

- **C** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Decision function values related to each class, per sample. In the two-class case, the shape is (n_samples,), giving the log likelihood ratio of the positive class.

**fit**(X, y)<br>
Fit LinearDiscriminantAnalysis model according to the given training data and parameters.

Changed in version 0.19: *store_covariance* has been moved to main constructor.

Changed in version 0.19: *tol* has been moved to main constructor.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.

- **y** [array-like of shape (n_samples,)] Target values.

**fit_transform**(X, y=None, **fit_params)<br>
Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit_params* and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.
Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict class labels for samples in X.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

predict_log_proba (X)
Estimate log probability.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

Returns

C [ndarray of shape (n_samples, n_classes)] Estimated log probabilities.

predict_proba (X)
Estimate probability.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

Returns

C [ndarray of shape (n_samples, n_classes)] Estimated probabilities.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.
set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)

Project data to maximize class separation.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

Returns

X_new [ndarray of shape (n_samples, n_components)] Transformed data.

7.9.2 sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

class sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis(**kwargs)

Quadratic Discriminant Analysis

A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Bayes’ rule.

The model fits a Gaussian density to each class.

New in version 0.17: QuadraticDiscriminantAnalysis

Read more in the User Guide.

Parameters

priors [ndarray of shape (n_classes,), default=None] Class priors. By default, the class proportions are inferred from the training data.

reg_param [float, default=0.0] Regularizes the per-class covariance estimates by transforming \( S_2 \) as \( S_2 = (1 - \text{reg\_param}) \times S_2 + \text{reg\_param} \times \text{np. eye}(n\_features) \), where \( S_2 \) corresponds to the scaling_ attribute of a given class.
store_covariance [bool, default=False] If True, the class covariance matrices are explicitely computed and stored in the self.covariance_ attribute.

New in version 0.17.

tol [float, default=1.0e-4] Absolute threshold for a singular value to be considered significant, used to estimate the rank of \(X_k\) where \(X_k\) is the centered matrix of samples in class k. This parameter does not affect the predictions. It only controls a warning that is raised when features are considered to be colinear.

New in version 0.17.

Attributes

covariance_ [list of len n_classes of ndarray of shape (n_features, n_features)] For each class, gives the covariance matrix estimated using the samples of that class. The estimations are unbiased. Only present if store_covariance is True.

means_ [array-like of shape (n_classes, n_features)] Class-wise means.

priors_ [array-like of shape (n_classes,)] Class priors (sum to 1).

rotations_ [list of len n_classes of ndarray of shape (n_features, n_k)] For each class \(k\), an array of shape (n_features, n_k), where \(n_k = \min(n_{features}, \text{number of elements in class } k)\) It is the rotation of the Gaussian distribution, i.e. its principal axis. It corresponds to \(V\), the matrix of eigenvectors coming from the SVD of \(X_k = U S V^t\) where \(X_k\) is the centered matrix of samples from class \(k\).

scalings_ [list of len n_classes of ndarray of shape (n_k,)] For each class, contains the scaling of the Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate system. It corresponds to \(S^2 / (n_{samples} - 1)\), where \(S\) is the diagonal matrix of singular values from the SVD of \(X_k\), where \(X_k\) is the centered matrix of samples from class \(k\).

classes_ [ndarray of shape (n_classes,)] Unique class labels.

LinearDiscriminantAnalysis Linear Discriminant Analysis.

Examples

```python
>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
QuadraticDiscriminantAnalysis()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```
Methods

**decision_function**(X)  
Apply decision function to an array of samples.

**fit**(X, y)  
Fit the model according to the given training data and parameters.

**get_params**(deep)  
Get parameters for this estimator.

**predict**(X)  
Perform classification on an array of test vectors X.

**predict_log_proba**(X)  
Return log of posterior probabilities of classification.

**predict_proba**(X)  
Return posterior probabilities of classification.

**score**(X, y[, sample_weight])  
Return the mean accuracy on the given test data and labels.

**set_params**(**params**)  
Set the parameters of this estimator.

**decision_function**(X)

Apply decision function to an array of samples.

The decision function is equal (up to a constant factor) to the log-posterior of the model, i.e. \( \log p(y = k | x) \). In a binary classification setting this instead corresponds to the difference \( \log p(y = 1 | x) - \log p(y = 0 | x) \). See **Mathematical formulation of the LDA and QDA classifiers**.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

**Returns**

- **C** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Decision function values related to each class, per sample. In the two-class case, the shape is (n_samples,), giving the log likelihood ratio of the positive class.

**fit**(X, y)

Fit the model according to the given training data and parameters.

Changed in version 0.19: **store_covariances** has been moved to main constructor as **store_covariance**

Changed in version 0.19: **tol** has been moved to main constructor.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples,)] Target values (integers)

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict**(X)

Perform classification on an array of test vectors X.
The predicted class C for each sample in X is returned.

Parameters
- X [array-like of shape (n_samples, n_features)]

Returns
- C [ndarray of shape (n_samples,)]

**predict_log_proba** (X)
Return log of posterior probabilities of classification.

Parameters
- X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns
- C [ndarray of shape (n_samples, n_classes)] Posterior log-probabilities of classification per class.

**predict_proba** (X)
Return posterior probabilities of classification.

Parameters
- X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns
- C [ndarray of shape (n_samples, n_classes)] Posterior probabilities of classification per class.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
- X [array-like of shape (n_samples, n_features)] Test samples.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
- score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as **Pipeline**). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
- **params [dict] Estimator parameters.

Returns
Examples using `sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis`

- Classifier comparison
- Linear and Quadratic Discriminant Analysis with covariance ellipsoid

7.10 `sklearn.dummy`: Dummy estimators

**User guide:** See the [Metrics and scoring: quantifying the quality of predictions](#) section for further details.

<table>
<thead>
<tr>
<th><code>dummy.DummyClassifier(**kwargs)</code></th>
<th>DummyClassifier is a classifier that makes predictions using simple rules.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dummy.DummyRegressor(**kwargs)</code></td>
<td>DummyRegressor is a regressor that makes predictions using simple rules.</td>
</tr>
</tbody>
</table>

7.10.1 `sklearn.dummy.DummyClassifier`

**class** `sklearn.dummy.DummyClassifier(**kwargs)`

DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the [User Guide](#).

New in version 0.13.

**Parameters**

- **strategy**: [{“stratified”, “most_frequent”, “prior”, “uniform”, “constant”}, default="prior"]
  Strategy to use to generate predictions.
  - “stratified”: generates predictions by respecting the training set’s class distribution.
  - “most_frequent”: always predicts the most frequent label in the training set.
  - “prior”: always predicts the class that maximizes the class prior (like “most_frequent”) and `predict_proba` returns the class prior.
  - “uniform”: generates predictions uniformly at random.
  - “constant”: always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class

  Changed in version 0.24: The default value of `strategy` has changed to “prior” in version 0.24.

- **random_state**: [int, RandomState instance or None, default=None] Controls the randomness to generate the predictions when `strategy='stratified'` or `strategy='uniform'`. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

- **constant**: [int or str or array-like of shape (n_outputs,)] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

**Attributes**

- **classes_**: [ndarray of shape (n_classes,) or list thereof] Class labels for each output.
n_classes_ [int or list of int] Number of label for each output.

class_prior_ [ndarray of shape (n_classes,) or list thereof] Probability of each class for each output.

n_outputs_ [int] Number of outputs.

sparse_output_ [bool] True if the array returned from predict is to be in sparse CSC format. Is automatically set to True if the input y is passed in sparse format.

Examples

```python
>>> import numpy as np
>>> from sklearn.dummy import DummyClassifier
>>> X = np.array([-1, 1, 1, 1])
>>> y = np.array([0, 1, 1, 1])
>>> dummy_clf = DummyClassifier(strategy="most_frequent")
>>> dummy_clf.fit(X, y)
DummyClassifier(strategy='most_frequent')
>>> dummy_clf.predict(X)
array([1, 1, 1, 1])
>>> dummy_clf.score(X, y)
0.75
```

</tr>
</tbody>
</table>

**fit (X, y, sample_weight=None)**

Fit the random classifier.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **self** [object]

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)] Test data.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Predicted target values for X.

predict_log_proba (X)
Return log probability estimates for the test vectors X.

Parameters

X [[array-like, object with finite length or shape]] Training data, requires length = n_samples

Returns

P [ndarray of shape (n_samples, n_classes) or list thereof] Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

predict_proba (X)
Return probability estimates for the test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)] Test data.

Returns

P [ndarray of shape (n_samples, n_classes) or list thereof] Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [None or array-like of shape (n_samples, n_features)] Test samples. Passing None as test samples gives the same result as passing real test samples, since DummyClassifier operates independently of the sampled observations.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.
**set_params(**params)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### 7.10.2 sklearn.dummy.DummyRegressor

**class sklearn.dummy.DummyRegressor(**kwargs)**

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

Read more in the *User Guide*.

New in version 0.13.

**Parameters**

**strategy** [[“mean”, “median”, “quantile”, “constant”], default=”mean”] Strategy to use to generate predictions.

- “mean”: always predicts the mean of the training set
- “median”: always predicts the median of the training set
- “quantile”: always predicts a specified quantile of the training set, provided with the quantile parameter.
- “constant”: always predicts a constant value that is provided by the user.

**constant** [int or float or array-like of shape (n_outputs,), default=None] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

**quantile** [float in [0.0, 1.0], default=None] The quantile to predict using the “quantile” strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

**Attributes**

**constant_** [ndarray of shape (1, n_outputs)] Mean or median or quantile of the training targets or constant value given by the user.

**n_outputs_** [int] Number of outputs.
Examples

```python
>>> import numpy as np
>>> from sklearn.dummy import DummyRegressor
>>> X = np.array([1.0, 2.0, 3.0, 4.0])
>>> y = np.array([2.0, 3.0, 5.0, 10.0])
>>> dummy_regr = DummyRegressor(strategy="mean")
>>> dummy_regr.fit(X, y)
DummyRegressor()
>>> dummy_regr.predict(X)
array([5., 5., 5., 5.])
>>> dummy_regr.score(X, y)
0.0
```

Methods

<table>
<thead>
<tr>
<th>Method</th>

</tr>
</tbody>
</table>

**fit** *(X, y, sample_weight=None)*

Fit the random regressor.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **self** [object]

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**predict** *(X, return_std=False)*

Perform classification on test vectors X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test data.
- **return_std** [bool, default=False] Whether to return the standard deviation of posterior prediction. All zeros in this case.
New in version 0.20.

**Returns**

- `y` [array-like of shape `(n_samples,)` or `(n_samples, n_outputs)`] Predicted target values for `X`.
- `y_std` [array-like of shape `(n_samples,)` or `(n_samples, n_outputs)`] Standard deviation of predictive distribution of query points.

**score** *(`X`, `y`, `sample_weight=None`)*

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean})^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- `X` [None or array-like of shape `(n_samples, n_features)`] Test samples. Passing None as test samples gives the same result as passing real test samples, since DummyRegressor operates independently of the sampled observations.
- `y` [array-like of shape `(n_samples,)` or `(n_samples, n_outputs)`] True values for `X`.
- `sample_weight` [array-like of shape `(n_samples,)`, default=None] Sample weights.

**Returns**

- `score` [float] $R^2$ of `self.predict(X)` wrt. `y`.

**set_params** *(**params)***

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

**Examples using sklearn.dummy.DummyRegressor**

- Poisson regression and non-normal loss
7.11 sklearn.ensemble: Ensemble Methods

The `sklearn.ensemble` module includes ensemble-based methods for classification, regression and anomaly detection.

User guide: See the Ensemble methods section for further details.

7.11.1 sklearn.ensemble.AdaBoostClassifier

class sklearn.ensemble.AdaBoostClassifier(**kwargs)
An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

This class implements the algorithm known as AdaBoost-SAMME [2].

Read more in the User Guide.

New in version 0.14.

Parameters

- `base_estimator` [object, default=None] The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper `classes_` and `n_classes_` attributes. If None, then the base estimator is `DecisionTreeClassifier` initialized with `max_depth=1`.

- `n_estimators` [int, default=50] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

- `learning_rate` [float, default=1.] Learning rate shrinks the contribution of each classifier by learning_rate. There is a trade-off between learning_rate and n_estimators.
algorithm ['SAMME', 'SAMME.R'], default='SAMME.R'] If 'SAMME.R' then use the SAMME.R real boosting algorithm. base_estimator must support calculation of class probabilities. If 'SAMME' then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

random_state [int, RandomState instance or None, default=None] Controls the random seed given at each base_estimator at each boosting iteration. Thus, it is only used when base_estimator exposes a random_state. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.
estimators_ [list of classifiers] The collection of fitted sub-estimators.
classes_ [ndarray of shape (n_classes,)] The classes labels.
n_classes_ [int] The number of classes.
estimator_weights_ [ndarray of floats] Weights for each estimator in the boosted ensemble.
estimator_errors_ [ndarray of floats] Classification error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] The impurity-based feature importances.

See also:

AdaBoostRegressor An AdaBoost regressor that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction.

GradientBoostingClassifier GB builds an additive model in a forward stage-wise fashion. Regression trees are fit on the negative gradient of the binomial or multinomial deviance loss function. Binary classification is a special case where only a single regression tree is induced.

sklearn.tree.DecisionTreeClassifier A non-parametric supervised learning method used for classification. Creates a model that predicts the value of a target variable by learning simple decision rules inferred from the data features.

### decision_function(X)

Compute the decision function of X.

**Parameters**

- **X**
  
  [[array-like, sparse matrix] of shape (n_samples, n_features)]
  
  The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

- **score**
  
  [ndarray of shape (n_samples, k)]
  
  The decision function of the input samples. The order of outputs is the same of that of the `classes_` attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

### property feature_importances_

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

**Warning:** impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

**Returns**

- **feature_importances_**
  
  [ndarray of shape (n_features,)]
  
  The feature importances.

### fit(X, y, sample_weight=None)

Build a boosted classifier from the training set (X, y).

**Parameters**
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] The target values (class labels).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns

self [object] Fitted estimator.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

y [ndarray of shape (n_samples,)] The predicted classes.

predict_log_proba (X)
Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

p [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

predict_proba (X)
Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

p  [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples.
y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

staged_decision_function (X)
Compute decision function of X for each boosting iteration.
This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

score  [generator of ndarray of shape (n_samples, k)] The decision function of the input samples. The order of outputs is the same of that of the classes_ attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in classes_, respectively.

staged_predict (X)
Return staged predictions for X.
The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.
This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Yields**

- **y** [generator of ndarray of shape (n_samples,)] The predicted classes.

**staged_predict_proba** *(X)*

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Yields**

- **p** [generator of ndarray of shape (n_samples,)] The class probabilities of the input samples. The order of outputs is the same of that of the `classes_` attribute.

**staged_score** *(X, y, sample_weight=None)*

Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

- **y** [array-like of shape (n_samples,)] Labels for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Yields**

- **z** [float]
Examples using sklearn.ensemble.AdaBoostClassifier

- Classifier comparison
- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees
- Discrete versus Real AdaBoost
- Plot the decision surfaces of ensembles of trees on the iris dataset

7.11.2 sklearn.ensemble.AdaBoostRegressor

class sklearn.ensemble.AdaBoostRegressor(**kwargs)

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the User Guide.

New in version 0.14.

Parameters

- base_estimator [object, default=None] The base estimator from which the boosted ensemble is built. If None, then the base estimator is DecisionTreeRegressor initialized with max_depth=3.
- n_estimators [int, default=50] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.
- learning_rate [float, default=1.] Learning rate shrinks the contribution of each regressor by learning_rate. There is a trade-off between learning_rate and n_estimators.
- loss [{'linear', 'square', 'exponential'}, default='linear'] The loss function to use when updating the weights after each boosting iteration.
- random_state [int, RandomState instance or None, default=None] Controls the random seed given at each base_estimator at each boosting iteration. Thus, it is only used when base_estimator exposes a random_state. In addition, it controls the bootstrap of the weights used to train the base_estimator at each boosting iteration. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

- base_estimator_ [estimator] The base estimator from which the ensemble is grown.
- estimators_ [list of classifiers] The collection of fitted sub-estimators.
- estimator_weights_ [ndarray of floats] Weights for each estimator in the boosted ensemble.
- estimator_errors_ [ndarray of floats] Regression error for each estimator in the boosted ensemble.
- feature_importances_ [ndarray of shape (n_features,)] The impurity-based feature importances.

sklearn.tree.DecisionTreeRegressor

References

[1], [2]

Examples

```python
>>> from sklearn.ensemble import AdaBoostRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, n_informative=2, ...
                   random_state=0, shuffle=False)
>>> regr = AdaBoostRegressor(random_state=0, n_estimators=100)
>>> regr.fit(X, y)
AdaBoostRegressor(n_estimators=100, random_state=0)
>>> regr.predict([[0, 0, 0, 0]])
array([4.7972...])
>>> regr.score(X, y)
0.9771...
```

Methods

**fit**(X, y[, sample_weight])

Build a boosted regressor from the training set (X, y).

**get_params**(deep)

Get parameters for this estimator.

**predict**(X)

Predict regression value for X.

**score**(X, y[, sample_weight])

Return the coefficient of determination $R^2$ of the prediction.

**set_params**(**params)

Set the parameters of this estimator.

**staged_predict**(X)

Return staged predictions for X.

**staged_score**(X, y[, sample_weight])

Return staged scores for X, y.

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**

**feature_importances_** [ndarray of shape (n_features,)] The feature importances.

**fit**(X, y, sample_weight=None)

Build a boosted regressor from the training set (X, y).

**Parameters**
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y  [array-like of shape (n_samples,)] The target values (real numbers).

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns
self  [object]

get_params  (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

predict  (X)
Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

y  [ndarray of shape (n_samples,)] The predicted regression values.

score  (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true}.mean())^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

`staged_predict (X)`
Return staged predictions for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.

Yields

y [generator of ndarray of shape (n_samples,)] The predicted regression values.

`staged_score (X, y, sample_weight=None)`
Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] Labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Yields

z [float]
A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [1]. If samples are drawn with replacement, then the method is known as Bagging [2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [4].

Read more in the User Guide.

New in version 0.15.

Parameters

- **base_estimator** [object, default=None] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a DecisionTreeClassifier.
- **n_estimators** [int, default=10] The number of base estimators in the ensemble.
- **max_samples** [int or float, default=1.0] The number of samples to draw from X to train each base estimator (with replacement by default, see bootstrap for more details).
  - If int, then draw max_samples samples.
  - If float, then draw max_samples * X.shape[0] samples.
- **max_features** [int or float, default=1.0] The number of features to draw from X to train each base estimator (without replacement by default, see bootstrap_features for more details).
  - If int, then draw max_features features.
  - If float, then draw max_features * X.shape[1] features.
- **bootstrap** [bool, default=True] Whether samples are drawn with replacement. If False, sampling without replacement is performed.
- **bootstrap_features** [bool, default=False] Whether features are drawn with replacement.
- **oob_score** [bool, default=False] Whether to use out-of-bag samples to estimate the generalization error.
- **warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See the Glossary.

New in version 0.17: warm_start constructor parameter.
n_jobs [int, default=None] The number of jobs to run in parallel for both fit and predict. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance or None, default=None] Controls the random resampling of the original dataset (sample wise and feature wise). If the base estimator accepts a random_state attribute, a different seed is generated for each instance in the ensemble. Pass an int for reproducible output across multiple function calls. See Glossary.

verbose [int, default=0] Controls the verbosity when fitting and predicting.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.
n_features_ [int] The number of features when fit is performed.
estimators_ [list of estimators] The collection of fitted base estimators.
estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.
estimators_features_ [list of arrays] The subset of drawn features for each base estimator.
classes_ [ndarray of shape (n_classes,)] The classes labels.
n_classes_ [int or list] The number of classes.
oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.
oob_decision_function_ [ndarray of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

`decision_function(X)`
Average of the decision functions of the base classifiers.

Parameters

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

- `score` [ndarray of shape (n_samples, k)] The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`. Regression and binary classification are special cases with k == 1, otherwise k==n_classes.

property `estimators_samples_`
The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

`fit(X, y, sample_weight=None)`
Build a Bagging ensemble of estimators from the training set (X, y).

Parameters

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

- `y` [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns

- `self` [object]
**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class for X.

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a `predict_proba` method, then it resorts to voting.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **y** [ndarray of shape (n_samples,)] The predicted classes.

**predict_log_proba** *(X)*

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **p** [ndarray of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict_proba** *(X)*

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities of the base estimators in the ensemble. If base estimators do not implement a `predict_proba` method, then it resorts to voting and the predicted class probabilities of an input sample represents the proportion of estimators predicting each class.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **p** [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.
Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [estimator instance] Estimator instance.

7.11.4 sklearn.ensemble.BaggingRegressor

class sklearn.ensemble.BaggingRegressor(**kwargs)

A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [1]. If samples are drawn with replacement, then the method is known as Bagging [2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [4].

Read more in the User Guide.

New in version 0.15.

Parameters

- **base_estimator** [object, default=None] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a DecisionTreeRegressor.
- **n_estimators** [int, default=10] The number of base estimators in the ensemble.
- **max_samples** [int or float, default=1.0] The number of samples to draw from X to train each base estimator (with replacement by default, see bootstrap for more details).
  - If int, then draw max_samples samples.
  - If float, then draw max_samples * X.shape[0] samples.
max_features [int or float, default=1.0] The number of features to draw from X to train each
base estimator (without replacement by default, see bootstrap_features for more
details).

- If int, then draw max_features features.
- If float, then draw max_features * X.shape[1] features.

bootstrap [bool, default=True] Whether samples are drawn with replacement. If False, sam-
pling without replacement is performed.

bootstrap_features [bool, default=False] Whether features are drawn with replacement.

oob_score [bool, default=False] Whether to use out-of-bag samples to estimate the generaliza-
tion error.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to
fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See
the Glossary.

n_jobs [int, default=None] The number of jobs to run in parallel for both fit and predict.
None means 1 unless in a joblib.parallel_backend context. -1 means using all
processors. See Glossary for more details.

random_state [int, RandomState instance or None, default=None] Controls the random resam-
ping of the original dataset (sample wise and feature wise). If the base estimator accepts a
random_state attribute, a different seed is generated for each instance in the ensemble.
Pass an int for reproducible output across multiple function calls. See Glossary.

verbose [int, default=0] Controls the verbosity when fitting and predicting.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

n_features_ [int] The number of features when fit is performed.

estimators_ [list of estimators] The collection of fitted sub-estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estima-
tor.

estimators_features_ [list of arrays] The subset of drawn features for each base estimator.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This
attribute exists only when oob_score is True.

oob_prediction_ [ndarray of shape (n_samples,)] Prediction computed with out-of-bag esti-
mate on the training set. If n_estimators is small it might be possible that a data point was
never left out during the bootstrap. In this case, oob_prediction_ might contain NaN.
This attribute exists only when oob_score is True.
References

[1], [2], [3], [4]

Examples

```python
>>> from sklearn.svm import SVR
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_samples=100, n_features=4,
...                        n_informative=2, n_targets=1,
...                        random_state=0, shuffle=False)
>>> regr = BaggingRegressor(base_estimator=SVR(),
...                          n_estimators=10, random_state=0).fit(X, y)
>>> regr.predict([[0, 0, 0, 0]])
array([-2.8720...])
```

Methods

- `fit(X, y[, sample_weight])`: Build a Bagging ensemble of estimators from the training set (X, y).
- `get_params([deep])`: Get parameters for this estimator.
- `predict(X)`: Predict regression target for X.
- `score(X, y[, sample_weight])`: Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)`: Set the parameters of this estimator.

**property estimators_samples_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit (X, y, sample_weight=None)**

Build a Bagging ensemble of estimators from the training set (X, y).

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.
- `y` ([array-like of shape (n_samples,))] The target values (class labels in classification, real numbers in regression).
- `sample_weight` ([array-like of shape (n_samples,), default=None]) Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

**Returns**

- `self` ([object])
**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

- **y** [ndarray of shape (n_samples,)] The predicted values.

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - rac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.ensemble.BaggingRegressor

- Single estimator versus bagging: bias-variance decomposition

7.11.5 sklearn.ensemble.ExtraTreesClassifier

class sklearn.ensemble.ExtraTreesClassifier(**kwargs)

An extra-trees classifier.

This class implements a meta estimator that fits a number of randomized decision trees (a.k.a. extra-trees) on
various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting.

Read more in the User Guide.

Parameters

n_estimators [int, default=100] The number of trees in the forest.

Changed in version 0.22: The default value of n_estimators changed from 10 to 100 in
0.22.

criterion ["gini", "entropy"], default="gini"] The function to measure the quality of a split.
Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.

max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are ex-

danded until all leaves are pure or until all leaves contain less than min_samples_split sam-

ples.

min_samples_split [int or float, default=2] The minimum number of samples required to split
an internal node:

- If int, then consider min_samples_split as the minimum number.

- If float, then min_samples_split is a fraction and ceil(min_samples_split 
  * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

min_samples_leaf [int or float, default=1] The minimum number of samples required to be
at a leaf node. A split point at any depth will only be considered if it leaves at least
min_samples_leaf training samples in each of the left and right branches. This may
have the effect of smoothing the model, especially in regression:

- If int, then consider min_samples_leaf as the minimum number.

- If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf 
  * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total
of weights (of all the input samples) required to be at a leaf node. Samples have equal weight
when sample_weight is not provided.
**max_features**  [{“auto”, “sqrt”, “log2”}, int or float, default=“auto”] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and round(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=sqrt(n_features).
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

**max_leaf_nodes**  [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease**  [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right.impurity} - \frac{N_{t,L}}{N_t} \times \text{left.impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,R}\) and \(N_{t,L}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split**  [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.

**bootstrap**  [bool, default=False] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score**  [bool, default=False] Whether to use out-of-bag samples to estimate the generalization accuracy.

**n_jobs**  [int, default=None] The number of jobs to run in parallel. fit, predict, decision_path and apply are all parallelized over the trees. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state**  [int, RandomState instance or None, default=None] Controls 3 sources of randomness:

- the bootstrapping of the samples used when building trees (if bootstrap=True)
• the sampling of the features to consider when looking for the best split at each node (if \( \text{max_features} < \text{n_features} \))
• the draw of the splits for each of the \text{max_features}

See \textit{Glossary} for details.

\textbf{verbose} \ [\text{int, default=0}] Controls the verbosity when fitting and predicting.

\textbf{warm_start} \ [\text{bool, default=False}] When set to \texttt{True}, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See \textit{the Glossary}.

\textbf{class_weight} \ [\{“balanced”, “balanced_subsample”\}, dict or list of dicts, default=None] Weights associated with classes in the form \{\text{class_label: weight}\}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of \text{y}.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be \{\{0: 1, 1: 1\}, \{0: 1, 1: 5\}, \{0: 1, 1: 1\}, \{0: 1, 1: 1\}\} instead of \{\{1:1\}, \{2:5\}, \{3:1\}, \{4:1\}\}.

The “balanced” mode uses the values of \text{y} to automatically adjust weights inversely proportional to class frequencies in the input data as \(n_{\text{samples}} / (n_{\text{classes}} * \text{np.bincount}(y))\)

The “balanced_subsample” mode is the same as “balanced” except that weights are computed based on the bootstrap sample for every tree grown.

For multi-output, the weights of each column of \text{y} will be multiplied.

Note that these weights will be multiplied with \text{sample_weight} (passed through the fit method) if \text{sample_weight} is specified.

\textbf{ccp_alpha} \ [\text{non-negative float, default=0.0}] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than \text{ccp_alpha} will be chosen. By default, no pruning is performed. See \textit{Minimal Cost-Complexity Pruning} for details.

New in version 0.22.

\textbf{max_samples} \ [\text{int or float, default=None}] If bootstrap is True, the number of samples to draw from \text{X} to train each base estimator.

• If None (default), then draw \(X.\text{shape}[0]\) samples.
• If int, then draw \text{max_samples} samples.
• If float, then draw \text{max_samples} * \text{X.shape[0]} samples. Thus, \text{max_samples} should be in the interval \((0, 1)\).

New in version 0.22.

\textbf{Attributes}

\textbf{base_estimator_} \ [\text{ExtraTreesClassifier}] The child estimator template used to create the collection of fitted sub-estimators.

\textbf{estimators_} \ [\text{list of DecisionTreeClassifier}] The collection of fitted sub-estimators.

\textbf{classes_} \ [\text{ndarray of shape (n_classes,) or a list of such arrays}] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
**n_classes_** [int or list] The number of classes (single output problem), or a list containing the number of classes for each output (multi-output problem).

**feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.

**n_features_** [int] The number of features when fit is performed.

**n_outputs_** [int] The number of outputs when fit is performed.

**oob_score_** [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

**oob_decision_function_** [ndarray of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

See also:

*sklearn.tree.ExtraTreeClassifier* Base classifier for this ensemble.

*RandomForestClassifier* Ensemble Classifier based on trees with optimal splits.

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

</table>

## apply(X)

Apply trees in the forest to X, return leaf indices.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- `X_leaves` ([ndarray of shape (n_samples, n_estimators)]) For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

## decision_path(X)

Return the decision path in the forest.

New in version 0.18.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- `indicator` [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.
- `n_nodes_ptr` [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

## property feature_importances_

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

**Returns**
**feature_importances_** [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit**(X, y, sample_weight=None)
Build a forest of trees from the training set (X, y).

**Parameters**

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

self [object]

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**predict**(X)
Predict class for X.

The predicted class of an input sample is a vote by the trees in the forest, weighted by their probability estimates. That is, the predicted class is the one with highest mean probability estimate across the trees.

**Parameters**

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

y [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes.

**predict_log_proba**(X)
Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the trees in the forest.

**Parameters**

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.
Returns

\[ p \] [ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict_proba** *(X)*

Predict class probabilities for \( X \).

The predicted class probabilities of an input sample are computed as the mean predicted class probabilities of the trees in the forest. The class probability of a single tree is the fraction of samples of the same class in a leaf.

Parameters

\( X \) [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns

\[ p \] [ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

\( X \) [array-like of shape (n_samples, n_features)] Test samples.

\( y \) [array-like of shape (n_samples,), or (n_samples, n_outputs)] True labels for \( X \).

\[ sample_weight \] [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. \( y \).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

\[ **params \] [dict] Estimator parameters.

Returns

\[ self \] [estimator instance] Estimator instance.
**Examples using `sklearn.ensemble.ExtraTreesClassifier`**

- **Pixel importances with a parallel forest of trees**
- **Feature importances with forests of trees**
- **Hashing feature transformation using Totally Random Trees**
- **Plot the decision surfaces of ensembles of trees on the iris dataset**

### 7.11.6 `sklearn.ensemble.ExtraTreesRegressor`

**class** `sklearn.ensemble.ExtraTreesRegressor(**kwargs)`

An extra-trees regressor.

This class implements a meta estimator that fits a number of randomized decision trees (a.k.a. extra-trees) on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. Read more in the [User Guide](#).

**Parameters**

- `n_estimators` [int, default=100] The number of trees in the forest.
  
  Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

- `criterion` [{'mse', 'mae'}, default='mse'] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion, and “mae” for the mean absolute error.
  
  New in version 0.18: Mean Absolute Error (MAE) criterion.

- `max_depth` [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

- `min_samples_split` [int or float, default=2] The minimum number of samples required to split an internal node:
  
  - If int, then consider `min_samples_split` as the minimum number.
  
  - If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.
  
  Changed in version 0.18: Added float values for fractions.

- `min_samples_leaf` [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
  
  - If int, then consider `min_samples_leaf` as the minimum number.
  
  - If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.
  
  Changed in version 0.18: Added float values for fractions.

- `min_weight_fraction_leaf` [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.
**max_features** ([“auto”, “sqrt”, “log2”], int or float, default=”auto”) The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and round(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=n_features.
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

**max_leaf_nodes** (int, default=None) Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** (float, default=0.0) A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t \_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t \_L}}{N_t} \times \text{left\_impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t \_L}\) is the number of samples in the left child, and \(N_{t \_R}\) is the number of samples in the right child.

\(N, N_t, N_{t \_R}\) and \(N_{t \_L}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** (float, default=None) Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.

**bootstrap** (bool, default=False) Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score** (bool, default=False) Whether to use out-of-bag samples to estimate the \(R^2\) on unseen data.

**n_jobs** (int, default=None) The number of jobs to run in parallel. \(fit, predict, decision\_path\) and \(apply\) are all parallelized over the trees. None means 1 unless in a joblib.parallel\_backend context. -1 means using all processors. See Glossary for more details.

**random_state** (int, RandomState instance or None, default=None) Controls 3 sources of randomness:

- the bootstrapping of the samples used when building trees (if bootstrap=True)
• the sampling of the features to consider when looking for the best split at each node (if \( \text{max\_features} < n\_\text{features} \))
• the draw of the splits for each of the \text{max\_features}

See Glossary for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**max_samples** [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.

* If None (default), then draw \( X.\text{shape}[0] \) samples.
* If int, then draw \( \text{max\_samples} \) samples.
* If float, then draw \( \text{max\_samples} \times X.\text{shape}[0] \) samples. Thus, \( \text{max\_samples} \) should be in the interval \((0, 1)\).

New in version 0.22.

**Attributes**

**base\_estimator**_ [ExtraTreeRegressor] The child estimator template used to create the collection of fitted sub-estimators.

**estimators**_ [list of DecisionTreeRegressor] The collection of fitted sub-estimators.

**feature\_importances**_ [ndarray of shape \( n\_\text{features} \)] The impurity-based feature importances.

**n\_features**_ [int] The number of features.

**n\_outputs**_ [int] The number of outputs.

**oob\_score**_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob\_score is True.

**oob\_prediction**_ [ndarray of shape \( n\_\text{samples} \)] Prediction computed with out-of-bag estimate on the training set. This attribute exists only when oob\_score is True.

See also:

[sklearn.tree.ExtraTreeRegressor](#) Base estimator for this ensemble.

[RandomForestRegressor](#) Ensemble regressor using trees with optimal splits.
Notes

The default values for the parameters controlling the size of the trees (e.g., max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

</tbody>
</table>

apply(X)

Apply trees in the forest to X, return leaf indices.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

- **X_leaves** [ndarray of shape (n_samples, n_estimators)] For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

decision_path(X)

Return the decision path in the forest.

New in version 0.18.
Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

indicator [(sparse matrix of shape (n_samples, n_nodes)) Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.
n_nodes_ptr [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

property feature_importances_
The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns

feature_importances_ [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit (X, y, sample_weight=None)
Build a forest of trees from the training set (X, y).

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.
predict \( (X) \)
Predict regression target for \( X \).

The predicted regression target of an input sample is computed as the mean predicted regression targets of the trees in the forest.

Parameters

\( X \) [[array-like, sparse matrix] of shape \((n_{\text{samples}}, n_{\text{features}})\)] The input samples. Internally, its dtype will be converted to dtype=\( \text{np.float32} \). If a sparse matrix is provided, it will be converted into a sparse \text{csr_matrix}.

Returns

\( y \) [ndarray of shape \((n_{\text{samples}},)\) or \((n_{\text{samples}}, n_{\text{outputs}})\)] The predicted values.

score \( (X, y, \text{sample\_weight}=\text{None}) \)
Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \( ((y_{\text{true}} - y_{\text{pred}})^2).\text{sum()} \) and \( v \) is the total sum of squares \( ((y_{\text{true}} - y_{\text{true}}.\text{mean()}^2).\text{sum()} \).

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

Parameters

\( X \) [array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape \((n_{\text{samples}}, n_{\text{samples\_fitted}})\), where \( n_{\text{samples\_fitted}} \) is the number of samples used in the fitting for the estimator.

\( y \) [array-like of shape \((n_{\text{samples}},)\) or \((n_{\text{samples}}, n_{\text{outputs}})\)] True values for \( X \).

\( \text{sample\_weight} \) [array-like of shape \((n_{\text{samples}},)\), default=None] Sample weights.

Returns

score [float] \( R^2 \) of self.predict \( (X) \) wrt. \( y \).

Notes

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of \text{r2\_score}. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**\text{params} \)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<\text{component}>\_\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

**\text{params} [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.ensemble.ExtraTreesRegressor`

- Face completion with a multi-output estimators
- Imputing missing values with variants of IterativeImputer

### 7.11.7 `sklearn.ensemble.GradientBoostingClassifier`

class `sklearn.ensemble.GradientBoostingClassifier(**kwargs)`

Gradient Boosting for classification.

GB builds an additive model in a forward stage-wise fashion; it allows for the optimization of arbitrary differentiable loss functions. In each stage, \( n_{\text{classes}} \) regression trees are fit on the negative gradient of the binomial or multinomial deviance loss function. Binary classification is a special case where only a single regression tree is induced.

Read more in the User Guide.

#### Parameters

- **loss** [‘deviance’, ‘exponential’], default=’deviance’] The loss function to be optimized. ‘deviance’ refers to deviance (= logistic regression) for classification with probabilistic outputs. For loss ‘exponential’ gradient boosting recovers the AdaBoost algorithm.

- **learning_rate** [float, default=0.1] Learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.

- **n_estimators** [int, default=100] The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.

- **subsample** [float, default=1.0] The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.

- **criterion** [‘friedman_mse’, ‘mse’, ‘mae’], default=’friedman_mse’] The function to measure the quality of a split. Supported criteria are ‘friedman_mse’ for the mean squared error with improvement score by Friedman, ‘mse’ for mean squared error, and ‘mae’ for the mean absolute error. The default value of ‘friedman_mse’ is generally the best as it can provide a better approximation in some cases.

  New in version 0.18.

  Deprecated since version 0.24: criterion=’mae’ is deprecated and will be removed in version 0.26. Use criterion=’friedman_mse’ or ‘mse’ instead, as trees should use a least-square criterion in Gradient Boosting.

- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:

  - If int, then consider min_samples_split as the minimum number.

  - If float, then min_samples_split is a fraction and \( \text{ceil}(\text{min_samples_split} \times n_{\text{samples}}) \) are the minimum number of samples for each split.

  Changed in version 0.18: Added float values for fractions.

- **min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
• If int, then consider `min_samples_leaf` as the minimum number.
• If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

`min_weight_fraction_leaf` [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

`max_depth` [int, default=3] The maximum depth of the individual regression estimators. The maximum depth limits the number of nodes in the tree. Tune this parameter for best performance; the best value depends on the interaction of the input variables.

`min_impurity_decrease` [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
N_t / N \times (impurity - N_t_R / N_t \times right_impurity
- N_t_L / N_t \times left_impurity)
\]

where `N` is the total number of samples, `N_t` is the number of samples at the current node, `N_t_L` is the number of samples in the left child, and `N_t_R` is the number of samples in the right child.

`N, N_t, N_t_R` and `N_t_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

`min_impurity_split` [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

`init` [estimator or ‘zero’, default=None] An estimator object that is used to compute the initial predictions. `init` has to provide `fit` and `predict_proba`. If ‘zero’, the initial raw predictions are set to zero. By default, a `DummyEstimator` predicting the classes priors is used.

`random_state` [int, RandomState instance or None, default=None] Controls the random seed given to each Tree estimator at each boosting iteration. In addition, it controls the random permutation of the features at each split (see Notes for more details). It also controls the random splitting of the training data to obtain a validation set if `n_iter_no_change` is not None. Pass an int for reproducible output across multiple function calls. See Glossary.

`max_features` [['auto', 'sqrt', 'log2'], int or float, default=None] The number of features to consider when looking for the best split:
• If int, then consider `max_features` features at each split.
• If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
• If ‘auto’, then `max_features=sqrt(n_features)`.
• If ‘sqrt’, then `max_features=sqrt(n_features)`.
• If ‘log2’, then `max_features=log2(n_features)`.
• If None, then `max_features=n_features`.

Choosing `max_features < n_features` leads to a reduction of variance and an increase in bias.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

`verbose` [int, default=0] Enable verbose output. If 1 then it prints progress and performance once in a while (the more trees the lower the frequency). If greater than 1 then it prints progress and performance for every tree.

`max_leaf_nodes` [int, default=None] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

`warm_start` [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just erase the previous solution. See the Glossary.

`validation_fraction` [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `n_iter_no_change` is set to an integer.

New in version 0.20.

`n_iter_no_change` [int, default=None] `n_iter_no_change` is used to decide if early stopping will be used to terminate training when validation score is not improving. By default it is set to None to disable early stopping. If set to a number, it will set aside `validation_fraction` size of the training data as validation and terminate training when validation score is not improving in all of the previous `n_iter_no_change` numbers of iterations. The split is stratified.

New in version 0.20.

`tol` [float, default=1e-4] Tolerance for the early stopping. When the loss is not improving by at least `tol` for `n_iter_no_change` iterations (if set to a number), the training stops.

New in version 0.20.

`ccp_alpha` [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

Attributes

`n_estimators_` [int] The number of estimators as selected by early stopping (if `n_iter_no_change` is specified). Otherwise it is set to `n_estimators`.

New in version 0.20.

`feature_importances_` [ndarray of shape (n_features,)] The impurity-based feature importances.

`oob_improvement_` [ndarray of shape (n_estimators,)] The improvement in loss (= deviance) on the out-of-bag samples relative to the previous iteration. `oob_improvement_[0]` is the improvement in loss of the first stage over the `init` estimator. Only available if `subsample < 1.0`
**train_score_** [ndarray of shape (n_estimators,)] The i-th score \(\text{train_score}_{[i]}\) is the deviance (= loss) of the model at iteration \(i\) on the in-bag sample. If \(\text{subsample} == 1\) this is the deviance on the training data.

**loss_** [LossFunction] The concrete \(\text{LossFunction}\) object.

**init_** [estimator] The estimator that provides the initial predictions. Set via the \text{init} argument or \text{loss.init_estimator}.

**estimators_** [ndarray of DecisionTreeRegressor of shape (n_estimators, \(\text{loss_.K}\))] The collection of fitted sub-estimators. \(\text{loss_.K}\) is 1 for binary classification, otherwise \(\text{n_classes}\).

**classes_** [ndarray of shape (n_classes,)] The classes labels.

**n_features_** [int] The number of data features.

**n_classes_** [int] The number of classes.

**max_features_** [int] The inferred value of \text{max_features}.

See also:

*HistGradientBoostingClassifier* Histogram-based Gradient Boosting Classification Tree.

*sklearn.tree.DecisionTreeClassifier* A decision tree classifier.

*RandomForestClassifier* A meta-estimator that fits a number of decision tree classifiers on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting.

*AdaBoostClassifier* A meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

**Notes**

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and \text{max_features=n_features}, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, \text{random_state} has to be fixed.

Examples

The following example shows how to fit a gradient boosting classifier with 100 decision stumps as weak learners.

```python
>>> from sklearn.datasets import make_hastie_10_2
>>> from sklearn.ensemble import GradientBoostingClassifier

>>> X, y = make_hastie_10_2(random_state=0)
>>> X_train, X_test = X[:2000], X[2000:]
>>> y_train, y_test = y[:2000], y[2000:]

>>> clf = GradientBoostingClassifier(n_estimators=100, learning_rate=1.0,
... max_depth=1, random_state=0).fit(X_train, y_train)
>>> clf.score(X_test, y_test)
0.913...
```

**apply (X)**

Apply trees in the ensemble to X, return leaf indices.

New in version 0.17.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted to a sparse csr_matrix.

**Returns**

- **X_leaves** [array-like of shape (n_samples, n_estimators, n_classes)] For each datapoint x in X and for each tree in the ensemble, return the index of the leaf x ends up in each estimator. In the case of binary classification n_classes is 1.

**decision_function (X)**

Compute the decision function of X.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Inter-
Finally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

- **score** [ndarray of shape (n_samples, n_classes) or (n_samples,)] The decision function of the input samples, which corresponds to the raw values predicted from the trees of the ensemble. The order of the classes corresponds to that in the attribute `classes_`. Regression and binary classification produce an array of shape (n_samples,).

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

**Returns**

- **feature_importances_** [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit** *(X, y, sample_weight=None, monitor=None)*

Fit the gradient boosting model.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

- **y** [array-like of shape (n_samples,)] Target values (strings or integers in classification, real numbers in regression) For classification, labels must correspond to classes.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

- **monitor** [callable, default=None] The monitor is called after each iteration with the current iteration, a reference to the estimator and the local variables of `_fit_stages` as keyword arguments `callable(i, self, locals())`. If the callable returns True the fitting procedure is stopped. The monitor can be used for various things such as computing held-out estimates, early stopping, model introspect, and snapshotting.

**Returns**

- **self** [object]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.
predict \((X)\)
Predict class for \(X\).

Parameters

\(X\) [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to \(\text{dtype=\text{np.float32}}\) and if a sparse matrix is provided to a sparse \(\text{csr_matrix}\).

Returns

\(y\) [ndarray of shape (n_samples,)] The predicted values.

predict_log_proba \((X)\)
Predict class log-probabilities for \(X\).

Parameters

\(X\) [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to \(\text{dtype=\text{np.float32}}\) and if a sparse matrix is provided to a sparse \(\text{csr_matrix}\).

Returns

\(p\) [ndarray of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute \(\text{classes}_-\).

Raises

\(\text{AttributeError}\) If the \(\text{loss}\) does not support probabilities.

predict_proba \((X)\)
Predict class probabilities for \(X\).

Parameters

\(X\) [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to \(\text{dtype=\text{np.float32}}\) and if a sparse matrix is provided to a sparse \(\text{csr_matrix}\).

Returns

\(p\) [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute \(\text{classes}_-\).

Raises

\(\text{AttributeError}\) If the \(\text{loss}\) does not support probabilities.

score \((X, y, sample\_weight=None)\)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

\(X\) [array-like of shape (n_samples, n_features)] Test samples.
\(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).
\(\text{sample\_weight}\) [array-like of shape (n_samples,), default=None] Sample weights.

Returns

\(\text{score}\) [float] Mean accuracy of \(\text{self.predict}(X)\) wrt. \(y\).
**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**staged_decision_function** (**X**)
Compute decision function of **X** for each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.

**Parameters**

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

score [generator of ndarray of shape (n_samples, k)] The decision function of the input samples, which corresponds to the raw values predicted from the trees of the ensemble. The classes corresponds to that in the attribute `classes_`. Regression and binary classification are special cases with k == 1, otherwise k==n_classes.

**staged_predict** (**X**)
Predict class at each stage for **X**.

This method allows monitoring (i.e. determine error on testing set) after each stage.

**Parameters**

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

y [generator of ndarray of shape (n_samples,)] The predicted value of the input samples.

**staged_predict_proba** (**X**)
Predict class probabilities at each stage for **X**.

This method allows monitoring (i.e. determine error on testing set) after each stage.

**Parameters**

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

y [generator of ndarray of shape (n_samples,)] The predicted value of the input samples.
Examples using sklearn.ensemble.GradientBoostingClassifier

- Gradient Boosting regularization
- Early stopping of Gradient Boosting
- Feature transformations with ensembles of trees
- Gradient Boosting Out-of-Bag estimates
- Feature discretization

7.11.8 sklearn.ensemble.GradientBoostingRegressor

class sklearn.ensemble.GradientBoostingRegressor(**kwargs)

Gradient Boosting for regression.

GB builds an additive model in a forward stage-wise fashion; it allows for the optimization of arbitrary differentiable loss functions. In each stage a regression tree is fit on the negative gradient of the given loss function.

Read more in the User Guide.

Parameters

loss [{‘ls’, ‘lad’, ‘huber’, ‘quantile’}, default=‘ls’] Loss function to be optimized. ‘ls’ refers to least squares regression. ‘lad’ (least absolute deviation) is a highly robust loss function solely based on order information of the input variables. ‘huber’ is a combination of the two. ‘quantile’ allows quantile regression (use alpha to specify the quantile).

learning_rate [float, default=0.1] Learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.

n_estimators [int, default=100] The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.

subsample [float, default=1.0] The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.

criterion [{‘friedman_mse’, ‘mse’, ‘mae’}, default=’friedman_mse’] The function to measure the quality of a split. Supported criteria are “friedman_mse” for the mean squared error with improvement score by Friedman, “mse” for mean squared error, and “mae” for the mean absolute error. The default value of “friedman_mse” is generally the best as it can provide a better approximation in some cases.

New in version 0.18.

Deprecated since version 0.24: criterion=’mae’ is deprecated and will be removed in version 0.26. The correct way of minimizing the absolute error is to use loss=’lad’ instead.

min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider min_samples_split as the minimum number.
- If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.
min_samples_leaf [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least \( \text{min_samples_leaf} \) training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider \( \text{min_samples_leaf} \) as the minimum number.
- If float, then \( \text{min_samples_leaf} \) is a fraction and \( \text{ceil}(\text{min_samples_leaf} \times n_{\text{samples}}) \) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_depth [int, default=3] Maximum depth of the individual regression estimators. The maximum depth limits the number of nodes in the tree. Tune this parameter for best performance; the best value depends on the interaction of the input variables.

min_impurity_decrease [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity})
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

\( N, N_t, N_{t,L} \) and \( N_{t,R} \) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

min_impurity_split [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: \( \text{min_impurity_split} \) has been deprecated in favor of \( \text{min_impurity_decrease} \) in 0.19. The default value of \( \text{min_impurity_split} \) has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use \( \text{min_impurity_decrease} \) instead.

init [estimator or ‘zero’, default=None] An estimator object that is used to compute the initial predictions. \( \text{init} \) has to provide \( \text{fit} \) and \( \text{predict} \). If ‘zero’, the initial raw predictions are set to zero. By default a DummyEstimator is used, predicting either the average target value (for loss='ls'), or a quantile for the other losses.

random_state [int, RandomState instance or None, default=None] Controls the random seed given to each Tree estimator at each boosting iteration. In addition, it controls the random permutation of the features at each split (see Notes for more details). It also controls the random splitting of the training data to obtain a validation set if \( \text{n_iter_no_change} \) is not None. Pass an int for reproducible output across multiple function calls. See Glossary.

max_features [{'auto', 'sqrt', 'log2'}, int or float, default=None] The number of features to consider when looking for the best split:

- If int, then consider \( \text{max_features} \) features at each split.
- If float, then \( \text{max_features} \) is a fraction and \( \text{int}(\text{max_features} \times n_{\text{features}}) \) features are considered at each split.
• If “auto”, then max_features=n_features.
• If “sqrt”, then max_features=sqrt(n_features).
• If “log2”, then max_features=log2(n_features).
• If None, then max_features=n_features.

Choosing max_features < n_features leads to a reduction of variance and an increase in bias.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

alpha [float, default=0.9] The alpha-quantile of the huber loss function and the quantile loss function. Only if loss='huber' or loss='quantile'.

verbose [int, default=0] Enable verbose output. If 1 then it prints progress and performance once in a while (the more trees the lower the frequency). If greater than 1 then it prints progress and performance for every tree.

max_leaf_nodes [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just erase the previous solution. See the Glossary.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if n_iter_no_change is set to an integer. New in version 0.20.

n_iter_no_change [int, default=None] n_iter_no_change is used to decide if early stopping will be used to terminate training when validation score is not improving. By default it is set to None to disable early stopping. If set to a number, it will set aside validation_fraction size of the training data as validation and terminate training when validation score is not improving in all of the previous n_iter_no_change numbers of iterations.

New in version 0.20.

tol [float, default=1e-4] Tolerance for the early stopping. When the loss is not improving by at least tol for n_iter_no_change iterations (if set to a number), the training stops.

New in version 0.20.

ccp_alpha [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

Attributes

feature_importances_ [ndarray of shape (n_features,)] The impurity-based feature importances.

oob_improvement_ [ndarray of shape (n_estimators,)] The improvement in loss (= deviance) on the out-of-bag samples relative to the previous iteration. oob_improvement_[0]
is the improvement in loss of the first stage over the init estimator. Only available if subsample < 1.0

train_score_[ndarray of shape (n_estimators,)] The i-th score train_score_[i] is the deviance (= loss) of the model at iteration i on the in-bag sample. If subsample == 1 this is the deviance on the training data.

init_ [estimator] The estimator that provides the initial predictions. Set via the init argument or loss.init_estimator.

estimators_ [ndarray of DecisionTreeRegressor of shape (n_estimators, 1)] The collection of fitted sub-estimators.

n_classes_ [int] The number of classes, set to 1 for regressors.

    Deprecated since version 0.24: Attribute n_classes_ was deprecated in version 0.24 and will be removed in 0.26.

n_estimators_ [int] The number of estimators as selected by early stopping (if n_iter_no_change is specified). Otherwise it is set to n_estimators.

n_features_ [int] The number of data features.

max_features_ [int] The inferred value of max_features.

See also:

HistGradientBoostingRegressor Histogram-based Gradient Boosting Classification Tree.

sklearn.tree.DecisionTreeRegressor A decision tree regressor.

sklearn.tree.RandomForestRegressor A random forest regressor.

Notes

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and max_features=n_features, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

Examples

```python
>>> from sklearn.datasets import make_regression
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> from sklearn.model_selection import train_test_split

... X, y = make_regression(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
>>> reg = GradientBoostingRegressor(random_state=0)
>>> reg.fit(X_train, y_train)
GradientBoostingRegressor(random_state=0)
>>> reg.predict(X_test[1:2])
array([-61.5228])
>>> reg.score(X_test, y_test)
0.46...
```

Methods

- `apply(X)`
  Apply trees in the ensemble to X, return leaf indices.
  
  New in version 0.17.

  Parameters
  - X: array-like, sparse matrix of shape (n_samples, n_features)
The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted to a sparse `csr_matrix`.

  Returns
  - X_leaves: array-like of shape (n_samples, n_estimators) For each datapoint x in X and for each tree in the ensemble, return the index of the leaf x ends up in each estimator.

- `feature_importances_`:
  The impurity-based feature importances.

  The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

  Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

  Returns
  - feature_importances_: ndarray of shape (n_features,) The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

7.11. sklearn.ensemble: Ensemble Methods
**fit** *(X, y, sample_weight=None, monitor=None)*

Fit the gradient boosting model.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.
- **y** [array-like of shape (n_samples,)] Target values (strings or integers in classification, real numbers in regression). For classification, labels must correspond to classes.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.
- **monitor** [callable, default=None] The monitor is called after each iteration with the current iteration, a reference to the estimator and the local variables of _fit_stages as keyword arguments callable(i, self, locals()). If the callable returns True the fitting procedure is stopped. The monitor can be used for various things such as computing held-out estimates, early stopping, model introspect, and snapshoting.

**Returns**

- **self** [object]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict regression target for X.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **y** [ndarray of shape (n_samples,)] The predicted values.

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean()}) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

staged_predict (X)

Predict regression target at each stage for X.

This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

y [generator of ndarray of shape (n_samples,)] The predicted value of the input samples.

Examples using sklearn.ensemble.GradientBoostingRegressor

- Plot individual and voting regression predictions
- Prediction Intervals for Gradient Boosting Regression
- Gradient Boosting regression
- Model Complexity Influence
class sklearn.ensemble.IsolationForest(**kwargs)

Return the anomaly score of each sample using the IsolationForest algorithm.

The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the User Guide.

New in version 0.18.

Parameters

n_estimators : int, default=100
    The number of base estimators in the ensemble.

max_samples : \"auto\", int or float, default=\"auto\"
    The number of samples to draw from X to train each base estimator.
    - If int, then draw max_samples samples.
    - If float, then draw max_samples * X.shape[0] samples.
    - If \"auto\", then max_samples=min(256, n_samples).

    If max_samples is larger than the number of samples provided, all samples will be used for all trees (no sampling).

contamination : \‘auto\’ or float, default=\‘auto\’
    The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the scores of the samples.
    - If \‘auto\’, the threshold is determined as in the original paper.
    - If float, the contamination should be in the range [0, 0.5].

    Changed in version 0.22: The default value of contamination changed from 0.1 to \‘auto\’.

max_features : int or float, default=1.0
    The number of features to draw from X to train each base estimator.
    - If int, then draw max_features features.
    - If float, then draw max_features * X.shape[1] features.

bootstrap : bool, default=False
    If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.

n_jobs : int, default=None
    The number of jobs to run in parallel for both fit and predict. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
random_state [int, RandomState instance or None, default=None] Controls the pseudo-
randomness of the selection of the feature and split values for each branching step and each
tree in the forest.

Pass an int for reproducible results across multiple function calls. See Glossary.

verbose [int, default=0] Controls the verbosity of the tree building process.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to
fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the
Glossary.

New in version 0.21.

Attributes

base_estimator_ [ExtraTreeRegressor instance] The child estimator template used to create the
collection of fitted sub-estimators.

estimators_ [list of ExtraTreeRegressor instances] The collection of fitted sub-estimators.

estimators_features_ [list of ndarray] The subset of drawn features for each base estimator.

estimators_samples_ [list of ndarray] The subset of drawn samples for each base esti-
mator.

max_samples_ [int] The actual number of samples.

offset_ [float] Offset used to define the decision function from the raw scores. We have the re-
lation: decision_function = score_samples - offset_. offset_ is de-
\new{fined as follows. When the contamination parameter is set to “auto”, the offset is equal to
-0.5 as the scores of inliers are close to 0 and the scores of outliers are close to -1. When
a contamination parameter different than “auto” is provided, the offset is defined in such
a way we obtain the expected number of outliers (samples with decision function < 0) in
training.

New in version 0.20.

n_features_ [int] The number of features when fit is performed.

See also:

sklearn.covariance.EllipticEnvelope An object for detecting outliers in a Gaussian distributed
dataset.

sklearn.svm.OneClassSVM Unsupervised Outlier Detection. Estimate the support of a high-
dimensional distribution. The implementation is based on libsvm.

sklearn.neighbors.LocalOutlierFactor Unsupervised Outlier Detection using Local Outlier
Factor (LOF).

Notes

The implementation is based on an ensemble of ExtraTreeRegressor. The maximum depth of each tree is set to
\cei{l}(\log_2(n)) where n is the number of samples used to build the tree (see (Liu et al., 2008) for more
details).
References

[1], [2]

Examples

```python
>>> from sklearn.ensemble import IsolationForest
>>> X = [[-1.1], [0.3], [0.5], [100]]
>>> clf = IsolationForest(random_state=0).fit(X)
>>> clf.predict([[0.1], [0], [90]])
array([1, 1, -1])
```

Methods

- `decision_function(X)`
  Average anomaly score of X of the base classifiers.

  The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

  The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations `n_left` in the leaf, the average path length of a `n_left` samples isolation tree is added.

  **Parameters**

  X  
  ([array-like, sparse matrix] of shape (n_samples, n_features))  The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

  **Returns**

  scores  
  [ndarray of shape (n_samples,)]  The anomaly score of the input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

- `fit(X, y=None, sample_weight=None)`
  Fit estimator.

  **Parameters**

  X  
  (array-like of shape (n_samples, n_features))  The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

  y  
  (array-like of shape (n_samples,))  The target values (integers that represent classes). If `y` is missing, then it is considered as 0.

  sample_weight  
  (array-like of shape (n_samples,))  Sample weights.

  **Returns**

  self  
  Returns self.

property `estimators_samples_`

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Use
  dtype=np.float32 for maximum efficiency. Sparse matrices are also supported, use
  sparse csc_matrix for maximum efficiency.

y  [Ignored] Not used, present for API consistency by convention.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None,
  then samples are equally weighted.

Returns
  self  [object] Fitted estimator.

fit_predict  (X, y=None)
  Perform fit on X and returns labels for X.
  Returns -1 for outliers and 1 for inliers.

Parameters
  X  [{array-like, sparse matrix, dataframe} of shape (n_samples, n_features)]
  y  [Ignored] Not used, present for API consistency by convention.

Returns
  y  [ndarray of shape (n_samples,)] 1 for inliers, -1 for outliers.

get_params  (deep=True)
  Get parameters for this estimator.

Parameters
  deep  [bool, default=True] If True, will return the parameters for this estimator and contained
  subobjects that are estimators.

Returns
  params  [dict] Parameter names mapped to their values.

predict  (X)
  Predict if a particular sample is an outlier or not.

Parameters
  X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Intern-
  ally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to
  a sparse csr_matrix.

Returns
  is_inlier  [ndarray of shape (n_samples,)] For each observation, tells whether or not (+1 or
  -1) it should be considered as an inlier according to the fitted model.

score_samples  (X)
  Opposite of the anomaly score defined in the original paper.

  The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.
  The measure of normality of an observation given a tree is the depth of the leaf containing this observation,
  which is equivalent to the number of splittings required to isolate this point. In case of several observations
  n_left in the leaf, the average path length of a n_left samples isolation tree is added.

Parameters
  X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples.
Returns

scores [ndarray of shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.ensemble.IsolationForest`

- `IsolationForest example`
- `Comparing anomaly detection algorithms for outlier detection on toy datasets`

### 7.11.10 sklearn.ensemble.RandomForestClassifier

class sklearn.ensemble.RandomForestClassifier(**kwargs)
A random forest classifier.

A random forest is a meta estimator that fits a number of decision tree classifiers on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. The sub-sample size is controlled with the `max_samples` parameter if `bootstrap=True` (default), otherwise the whole dataset is used to build each tree.

Read more in the `User Guide`.

Parameters

- **n_estimators** [int, default=100] The number of trees in the forest.
  
  Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

- **criterion** [“gini”, “entropy”], default=”gini“] The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain. Note: this parameter is tree-specific.

- **max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:
  
  - If int, then consider `min_samples_split` as the minimum number.
  
  - If float, then `min_samples_split` is a fraction and `ceiling(min_samples_split * n_samples)` are the minimum number of samples for each split.

  Changed in version 0.18: Added float values for fractions.
**min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider min_samples_leaf as the minimum number.
- If float, then min_samples_leaf is a fraction and \(\text{ceil}(\text{min_samples_leaf} \times n\_samples)\) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [{“auto”, “sqrt”, “log2”}, int or float, default=”auto”] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and \(\text{round}(\text{max_features} \times n\_features)\) features are considered at each split.
- If “auto”, then max_features=sqrt(n_features).
- If “sqrt”, then max_features=sqrt(n_features) (same as “auto”).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

**max_leaf_nodes** [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t\_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t\_L}}{N_t} \times \text{left\_impurity} \right)
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t\_L}\) is the number of samples in the left child, and \(N_{t\_R}\) is the number of samples in the right child.

\(N, N_t, N_{t\_R}\) and \(N_{t\_L}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.
**bootstrap** [bool, default=True] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score** [bool, default=False] Whether to use out-of-bag samples to estimate the generalization accuracy.

**n_jobs** [int, default=None] The number of jobs to run in parallel. `fit`, `predict`, `decision_path`, and `apply` are all parallelized over the trees. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See **Glossary** for more details.

**random_state** [int, RandomState instance or None, default=None] Controls both the randomness of the bootstrapping of the samples used when building trees (if `bootstrap=True`) and the sampling of the features to consider when looking for the best split at each node (if `max_features < n_features`). See **Glossary** for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See **the Glossary**.

**class_weight** [{“balanced”, “balanced_subsample”}, dict or list of dicts, default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multiclass weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[[0: 1, 1: 1], [0: 1, 1: 5], [0: 1, 1: 1], [0: 1, 1: 1]]` instead of `[[1:1], [2:5], [3:1], [4:1]]`.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

The “balanced_subsample” mode is the same as “balanced” except that weights are computed based on the bootstrap sample for every tree grown.

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See **Minimal Cost-Complexity Pruning** for details.

New in version 0.22.

**max_samples** [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.

- If None (default), then draw `X.shape[0]` samples.
- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples. Thus, `max_samples` should be in the interval `(0, 1)`.

New in version 0.22.
Attributes

**base_estimator**_  [DecisionTreeClassifier] The child estimator template used to create the collection of fitted sub-estimators.

**estimators**_  [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

**classes**_  [ndarray of shape (n_classes,) or a list of such arrays] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

**n_classes**_  [int or list] The number of classes (single output problem), or a list containing the number of classes for each output (multi-output problem).

**n_features**_  [int] The number of features when fit is performed.

**n_outputs**_  [int] The number of outputs when fit is performed.

**feature_importances**_  [ndarray of shape (n_features,)] The impurity-based feature importances.

**oob_score**_  [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

**oob_decision_function**_  [ndarray of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

See also:

**DecisionTreeClassifier**, **ExtraTreesClassifier**

Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data, max_features=n_features and bootstrap=False, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

**apply** *(X)*

Apply trees in the forest to X, return leaf indices.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **X_leaves** *(ndarray of shape (n_samples, n_estimators))* For each datpoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

**decision_path** *(X)*

Return the decision path in the forest.

New in version 0.18.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **indicator** *(sparse matrix of shape (n_samples, n_nodes))* Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.
**n_nodes_ptr** [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

**property feature_importances_**
The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**

**feature_importances_** [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit** *(X, y, sample_weight=None)*
Build a forest of trees from the training set (X, y).

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

**self** [object]

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**predict** *(X)*
Predict class for X.

The predicted class of an input sample is a vote by the trees in the forest, weighted by their probability estimates. That is, the predicted class is the one with highest mean probability estimate across the trees.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**
The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the trees in the forest.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtypes will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- `p` ([ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict_proba** (X)

Predict class probabilities for X.

The predicted class probabilities of an input sample are computed as the mean predicted class probabilities of the trees in the forest. The class probability of a single tree is the fraction of samples of the same class in a leaf.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtypes will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- `p` ([ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Test samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for `X`.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `score` [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params** (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**
**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

### 7.11.11 sklearn.ensemble.RandomForestRegressor

**class** sklearn.ensemble.RandomForestRegressor(**kwargs)

A random forest regressor.

A random forest is a meta estimator that fits a number of classifying decision trees on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. The sub-sample size is controlled with the `max_samples` parameter if `bootstrap=True` (default), otherwise the whole dataset is used to build each tree.

Read more in the *User Guide*.

**Parameters**

- `n_estimators` [int, default=100] The number of trees in the forest.
  
  Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

- `criterion` [""mse", "mae"", default="mse"] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion, and “mae” for the mean absolute error.

  New in version 0.18: Mean Absolute Error (MAE) criterion.
max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:
- If int, then consider min_samples_split as the minimum number.
- If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

min_samples_leaf [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression:
- If int, then consider min_samples_leaf as the minimum number.
- If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_features [“auto”, “sqrt”, “log2”], int or float, default=”auto”] The number of features to consider when looking for the best split:
- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and round(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=n_features.
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

max_leaf_nodes [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

min_impurity_decrease [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.
N, N_t, N_t_R and N_t_L all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.

**bootstrap** [bool, default=True] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score** [bool, default=False] whether to use out-of-bag samples to estimate the R^2 on unseen data.

**n_jobs** [int, default=None] The number of jobs to run in parallel. fit, predict, decision_path and apply are all parallelized over the trees. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance or None, default=None] Controls both the randomness of the bootstrapping of the samples used when building trees (if bootstrap=True) and the sampling of the features to consider when looking for the best split at each node (if max_features < n_features). See Glossary for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**max_samples** [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.

- If None (default), then draw X.shape[0] samples.
- If int, then draw max_samples samples.
- If float, then draw max_samples * X.shape[0] samples. Thus, max_samples should be in the interval (0, 1).

New in version 0.22.

Attributes

**base_estimator_** [DecisionTreeRegressor] The child estimator template used to create the collection of fitted sub-estimators.

**estimators_** [list of DecisionTreeRegressor] The collection of fitted sub-estimators.

**feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.

**n_features_** [int] The number of features when fit is performed.
**n_outputs_** [int] The number of outputs when fit is performed.

**oob_score_** [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

**oob_prediction_** [ndarray of shape (n_samples,)] Prediction computed with out-of-bag estimate on the training set. This attribute exists only when oob_score is True.

See also:

**DecisionTreeRegressor**, **ExtraTreesRegressor**

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data, max_features=n_features and bootstrap=False, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

The default value max_features="auto" uses n_features rather than n_features / 3. The latter was originally suggested in [1], whereas the former was more recently justified empirically in [2].

**Examples**

```python
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, n_informative=2, ...
    ... random_state=0, shuffle=False)

>>> regr = RandomForestRegressor(max_depth=2, random_state=0)

>>> regr.fit(X, y)

>>> print(regr.predict([[0, 0, 0, 0]]))
[-8.32987858]
```

**Methods**

- **apply(X)**
  Apply trees in the forest to X, return leaf indices.

- **decision_path(X)**
  Return the decision path in the forest.

- **fit(X, y[, sample_weight])**
  Build a forest of trees from the training set (X, y).

- **get_params([deep])**
  Get parameters for this estimator.

- **predict(X)**
  Predict regression target for X.

- **score(X, y[, sample_weight])**
  Return the coefficient of determination $R^2$ of the prediction.
**apply** (*X*)

Apply trees in the forest to *X*, return leaf indices.

**Parameters**

* *X* [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

*X_leaves* [ndarray of shape (n_samples, n_estimators)] For each datapoint *x* in *X* and for each tree in the forest, return the index of the leaf *x* ends up in.

**decision_path** (*X*)

Return the decision path in the forest.

New in version 0.18.

**Parameters**

* *X* [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

*indicator* [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.

*n_nodes_ptr* [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**

*feature_importances_* [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit** (*X, y, sample_weight=None*)

Build a forest of trees from the training set (*X, y*).

**Parameters**

* *X* [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.

* *y* [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).
**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

self [object]

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**predict**(X)
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the trees in the forest.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dttype will be converted to dttype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

y [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The predicted values.

**score**(X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for $X$.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] $R^2$ of self.predict(X) wrt $y$. 

1932 Chapter 7. API Reference
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params(**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict]** Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.ensemble.RandomForestRegressor`

- Plot individual and voting regression predictions
- Comparing random forests and the multi-output meta estimator
- Combine predictors using stacking
- Prediction Latency
- Imputing missing values before building an estimator

### 7.11.12 sklearn.ensemble.RandomTreesEmbedding

**class sklearn.ensemble.RandomTreesEmbedding(**kwargs)**

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a binary coding with as many ones as there are trees in the forest.

The dimensionality of the resulting representation is $n_{out} \leq n_{estimators} \times max\_leaf\_nodes$. If `max_leaf_nodes == None`, the number of leaf nodes is at most $n_{estimators} \times 2^{max\_depth}$.

Read more in the `User Guide`.

Parameters

- **n_estimators [int, default=100]** Number of trees in the forest.
  
  Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

- **max_depth [int, default=5]** The maximum depth of each tree. If `None`, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

- **min_samples_split [int or float, default=2]** The minimum number of samples required to split an internal node:
  
  - If int, then consider `min_samples_split` as the minimum number.
• If float, then `min_samples_split` is a fraction and `ceil(min_samples_split \times n_samples)` is the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

`min_samples_leaf` [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

• If int, then consider `min_samples_leaf` as the minimum number.
• If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf \times n_samples)` is the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

`min_weight_fraction_leaf` [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

`max_leaf_nodes` [int, default=None] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

`min_impurity_decrease` [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right\_impurity} - \frac{N_{t,L}}{N_t} \times \text{left\_impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,R}\) and \(N_{t,L}\) all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

`min_impurity_split` [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

`sparse_output` [bool, default=True] Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

`n_jobs` [int, default=None] The number of jobs to run in parallel. `fit, transform, decision_path` and `apply` are all parallelized over the trees. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

`random_state` [int, RandomState instance or None, default=None] Controls the generation of the random \(y\) used to fit the trees and the draw of the splits for each feature at the trees’ nodes. See `Glossary` for details.

`verbose` [int, default=0] Controls the verbosity when fitting and predicting.
**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

Attributes

- **base_estimator_** [DecisionTreeClassifier instance] The child estimator template used to create the collection of fitted sub-estimators.
- **estimators_** [list of DecisionTreeClassifier instances] The collection of fitted sub-estimators.
- **feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **one_hot_encoder_** [OneHotEncoder instance] One-hot encoder used to create the sparse embedding.

</tr>
</tbody>
</table>

**apply**(X)

Apply trees in the forest to X, return leaf indices.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Inter-
nally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

X_leaves [ndarray of shape (n_samples, n_estimators)] For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

decision_path (X)
Return the decision path in the forest.
New in version 0.18.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

indicator [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.
n_nodes_ptr [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

property feature_importances_
The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns

feature_importances_ [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit (X, y=None, sample_weight=None)
Fit estimator.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Use dtype=np.float32 for maximum efficiency. Sparse matrices are also supported, use sparse csc_matrix for maximum efficiency.
y [Ignored] Not used, present for API consistency by convention.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

self [object]
**fit_transform** (*X*, *y=None, sample_weight=None*)
Fit estimator and transform dataset.

- **Parameters**
  - *X* ([array-like, sparse matrix] of shape (n_samples, n_features)) Input data used to build forests. Use `dtype=np.float32` for maximum efficiency.
  - *y* [Ignored] Not used, present for API consistency by convention.
  - *sample_weight* [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

- **Returns**
  - *X_transformed* [sparse matrix of shape (n_samples, n_out)] Transformed dataset.

**get_params** (*deep=True*)
Get parameters for this estimator.

- **Parameters**
  - *deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

- **Returns**
  - *params* [dict] Parameter names mapped to their values.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

- **Parameters**
  - **params** [dict] Estimator parameters.

- **Returns**
  - *self* [dict] Estimator instance.

**transform** (*X*)
Transform dataset.

- **Parameters**
  - *X* ([array-like, sparse matrix] of shape (n_samples, n_features)) Input data to be transformed. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csr_matrix` for maximum efficiency.

- **Returns**
  - *X_transformed* [sparse matrix of shape (n_samples, n_out)] Transformed dataset.
Examples using `sklearn.ensemble.RandomTreesEmbedding`

- Hashing feature transformation using Totally Random Trees
- Feature transformations with ensembles of trees

### 7.11.13 `sklearn.ensemble.StackingClassifier`

class `sklearn.ensemble.StackingClassifier(**kwargs)`

Stack of estimators with a final classifier.

Stacked generalization consists in stacking the output of individual estimator and use a classifier to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that `estimators_` are fitted on the full `X` while `final_estimator_` is trained using cross-validated predictions of the base estimators using `cross_val_predict`.

Read more in the [User Guide](#).

New in version 0.22.

**Parameters**

- **estimators** [list of (str, estimator)] Base estimators which will be stacked together. Each element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An estimator can be set to ‘drop’ using `set_params`.

- **final_estimator** [estimator, default=None] A classifier which will be used to combine the base estimators. The default classifier is a `LogisticRegression`.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in `cross_val_predict` to train `final_estimator`. Possible inputs for `cv` are:
  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a (Stratified) KFold,
  - An object to be used as a cross-validation generator,
  - An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer [User Guide](#) for the various cross-validation strategies that can be used here.

---

**Note:** A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. `cv` is not used for model evaluation but for prediction.

- **stack_method** [‘auto’, ‘predict_proba’, ‘decision_function’, ‘predict’], default=’auto’] Methods called for each base estimator. It can be:
  - if ‘auto’, it will try to invoke, for each estimator, 'predict_proba', 'decision_function' or 'predict' in that order.
• otherwise, one of 'predict_proba', 'decision_function' or 'predict'. If the method is not implemented by the estimator, it will raise an error.

n_jobs [int, default=None] The number of jobs to run in parallel all estimators fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

passthrough [bool, default=False] When False, only the predictions of estimators will be used as training data for final_estimator. When True, the final_estimator is trained on the predictions as well as the original training data.

verbose [int, default=0] Verbosity level.

Attributes

classes_ [ndarray of shape (n_classes,)] Class labels.
estimators_ [list of estimators] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to 'drop', it will not appear in estimators_.
named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.
final_estimator_ [estimator] The classifier which predicts given the output of estimators_.
stack_method_ [list of str] The method used by each base estimator.

Notes

When predict_proba is used by each estimator (i.e. most of the time for stack_method='auto' or specifically for stack_method='predict_proba'), The first column predicted by each estimator will be dropped in the case of a binary classification problem. Indeed, both feature will be perfectly collinear.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.svm import LinearSVC
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.ensemble import StackingClassifier
>>> X, y = load_iris(return_X_y=True)
>>> estimators = [
...    ('rf', RandomForestClassifier(n_estimators=10, random_state=42)),
...    ('svr', make_pipeline(StandardScaler(),
...        LinearSVC(random_state=42))
...]
>>> clf = StackingClassifier(  
...    estimators=estimators, final_estimator=LogisticRegression()  
...)
```

(continues on next page)
scikit-learn user guide, Release 0.24.dev0

Methods

decision_function(X)  Predict decision function for samples in X using final_estimator_.decision_function.
fit(X, y[, sample_weight])  Fit the estimators.
fit_transform(X[, y])  Fit to data, then transform it.
get_params([deep])  Get the parameters of an estimator from the ensemble.
predict(X, **predict_params)  Predict target for X.
predict_proba(X)  Predict class probabilities for X using final_estimator_.predict_proba.
score(X, y[, sample_weight])  Return the mean accuracy on the given test data and labels.
set_params(**params)  Set the parameters of an estimator from the ensemble.
transform(X)  Return class labels or probabilities for X for each estimator.

decision_function(X)
   Predict decision function for samples in X using final_estimator_.decision_function.

Parameters

   X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

   decisions [ndarray of shape (n_samples,), (n_samples, n_classes), or (n_samples, n_classes * (n_classes-1) / 2)] The decision function computed the final estimator.

fit (X, y, sample_weight=None)
   Fit the estimators.

Parameters

   X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

   y [array-like of shape (n_samples,)] Target values.

   sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

   self [object]

fit_transform (X, y=None, **fit_params)
   Fit to data, then transform it.
Fits transformer to $X$ and $y$ with optional parameters `fit_params` and returns a transformed version of $X$.

**Parameters**

- **$X$** [array-like of shape (n_samples, n_features)] Input samples.
- **$y$** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **`fit_params`** [dict] Additional fit parameters.

**Returns**

- **$X_{\text{new}}$** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the `estimators` parameter.

**Parameters**

- **deep** [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

property n_features_in_

Number of features seen during `fit`.

**predict**(X, **`predict_params`)

Predict target for $X$.

**Parameters**

- **$X$** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**`predict_params`** [dict of str -> obj] Parameters to the `predict` called by the `final_estimator`. Note that this may be used to return uncertainties from some estimators with `return_std` or `return_cov`. Be aware that it will only accounts for uncertainty in the final estimator.

**Returns**

- **$y_{\text{pred}}$** [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

**predict_proba**(X)

Predict class probabilities for $X$ using `final_estimator_.predict_proba`.

**Parameters**

- **$X$** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **`probabilities`** [ndarray of shape (n_samples, n_classes) or list of ndarray of shape (n_output,)] The class probabilities of the input samples.

**score**(X, y, **sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.
Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of an estimator from the ensemble.
Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in estimators.

Parameters

**params [keyword arguments] Specific parameters using e.g. set_params(parameter_name=new_value). In addition, to setting the parameters of the estimator, the individual estimator of the estimators can also be set, or can be removed by setting them to ‘drop’.

transform(X)
Return class labels or probabilities for X for each estimator.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

y_preds [ndarray of shape (n_samples, n_estimators) or (n_samples, n_classes * n_estimators)] Prediction outputs for each estimator.

Examples using sklearn.ensemble.StackingClassifier

• Release Highlights for scikit-learn 0.22

7.11.14 sklearn.ensemble.StackingRegressor

class sklearn.ensemble.StackingRegressor(**kwargs)
Stack of estimators with a final regressor.

Stacked generalization consists in stacking the output of individual estimator and use a regressor to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that estimators_ are fitted on the full X while final_estimator_ is trained using cross-validated predictions of the base estimators using cross_val_predict.

Read more in the User Guide.
New in version 0.22.

Parameters
estimators [list of (str, estimator)] Base estimators which will be stacked together. Each
element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An
estimator can be set to 'drop' using set_params.

final_estimator [estimator, default=None] A regressor which will be used to combine the base
estimators. The default regressor is a RidgeCV.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation
splitting strategy used in cross_val_predict to train final_estimator. Possible
inputs for cv are:

• None, to use the default 5-fold cross validation,

• integer, to specify the number of folds in a (Stratified) KFold,

• An object to be used as a cross-validation generator,

• An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass,
StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Note: A larger number of split will provide no benefits if the number of training samples
is large enough. Indeed, the training time will increase. cv is not used for model evaluation
but for prediction.

n_jobs [int, default=None] The number of jobs to run in parallel for fit of all estimators.
None means 1 unless in a joblib.parallel_backend context. -1 means using all
processors. See Glossary for more details.

passthrough [bool, default=False] When False, only the predictions of estimators will be used
as training data for final_estimator. When True, the final_estimator is trained
on the predictions as well as the original training data.

verbose [int, default=0] Verbosity level.

Attributes

estimators_ [list of estimator] The elements of the estimators parameter, having been fit-
ted on the training data. If an estimator has been set to 'drop', it will not appear in
estimators_.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

final_estimator_ [estimator] The regressor to stacked the base estimators fitted.

**fit** *(X, y, sample_weight=None)*

Fit the estimators.

**Parameters**

- **X** *[[array-like, sparse matrix] of shape (n_samples, n_features)]* Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** *[array-like of shape (n_samples,)]* Target values.
- **sample_weight** *[array-like of shape (n_samples,), default=None]* Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

**Returns**

- **self** *[object]*

**fit_transform** *(X, y=None, **fit_params)*
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params(**deep=True)

Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

Parameters

- **deep** [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

property n_features_in_

Number of features seen during fit.

predict(X, **predict_params)

Predict target for X.

Parameters

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **predict_params** [dict of str -> obj] Parameters to the predict called by the final_estimator. Note that this may be used to return uncertainties from some estimators with return_std or return_cov. Be aware that it will only accounts for uncertainty in the final estimator.

Returns

- **y_pred** [ndarray of shape (n_samples, n_outputs)] Predicted targets.

score(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes
The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in estimators.

Parameters

**params [keyword arguments] Specific parameters using e.g. set_params(parameter_name=new_value). In addition, to setting the parameters of the estimator, the individual estimator of the estimators can also be set, or can be removed by setting them to ‘drop’.

transform(X)
Return the predictions for X for each estimator.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

y_preds [ndarray of shape (n_samples, n_estimators)] Prediction outputs for each estimator.

Examples using sklearn.ensemble.StackingRegressor

- Combine predictors using stacking

7.11.15 sklearn.ensemble.VotingClassifier

class sklearn.ensemble.VotingClassifier(**kwargs)
Soft Voting/Majority Rule classifier for unfitted estimators.

Read more in the User Guide.

New in version 0.17.

Parameters

estimators [list of (str, estimator) tuples] Invoking the fit method on the VotingClassifier will fit clones of those original estimators that will be stored in the class attribute self.estimators_. An estimator can be set to 'drop' using set_params.
Changed in version 0.21: 'drop' is accepted. Using None was deprecated in 0.22 and support was removed in 0.24.

voting [{'hard', 'soft'}, default='hard'] If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.

weights [array-like of shape (n_classifiers,), default=None] Sequence of weights (float or int) to weight the occurrences of predicted class labels (hard voting) or class probabilities before averaging (soft voting). Uses uniform weights if None.

n_jobs [int, default=None] The number of jobs to run in parallel for fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.18.

flatten_transform [bool, default=True] Affects shape of transform output only when voting='soft' If voting='soft' and flatten_transform=True, transform method returns matrix with shape (n_samples, n_classifiers * n_classes). If flatten_transform=False, it returns (n_classifiers, n_samples, n_classes).

verbose [bool, default=False] If True, the time elapsed while fitting will be printed as it is completed.

New in version 0.23.

Attributes

estimators_ [list of classifiers] The collection of fitted sub-estimators as defined in estimators that are not 'drop'.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

classes_ [array-like of shape (n_predictions,)] The classes labels.

VotingRegressor Prediction voting regressor.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier
>>> clf1 = LogisticRegression(multi_class='multinomial', random_state=1)
>>> clf2 = RandomForestClassifier(n_estimators=50, random_state=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 1, 2])
>>> eclf1 = VotingClassifier(estimators=[
...   ('lr', clf1), ('rf', clf2), ('gnb', clf3)], voting='hard')
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2]
>>> np.array_equal(eclf1.named_estimators_.lr.predict(X), 
...   eclf1.named_estimators_['lr'].predict(X))
(continues on next page)
```
True
```python
>>> eclf2 = VotingClassifier(estimators=[
... ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
... voting='soft')
>>> eclf2 = eclf2.fit(X, y)
>>> print(eclf2.predict(X))
[1 1 1 2 2 2]
```
```python
>>> eclf3 = VotingClassifier(estimators=[
... ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
... voting='soft', weights=[2,1,1],
... flatten_transform=True)
>>> eclf3 = eclf3.fit(X, y)
>>> print(eclf3.predict(X))
[1 1 1 2 2 2]
```
```python
>>> print(eclf3.transform(X).shape)
(6, 6)
```

**Methods**

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples,)] Target values.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

**Returns**

- **self** [object]            

- **fit_transform** (X, y=None, **fit_params)** Return predictions for X for each estimator.

Return predictions for X for each estimator.
Parameters

**X**  [[array-like, sparse matrix, dataframe] of shape (n_samples, n_features)] Input samples

**y**  [ndarray of shape (n_samples,), default=None] Target values (None for unsupervised transformations).

**fit_params**  [dict] Additional fit parameters.

Returns

**X_new**  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

Parameters

**deep**  [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

**predict**(X)

Predict class labels for X.

Parameters

**X**  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

**maj**  [array-like of shape (n_samples,)] Predicted class labels.

**property predict_proba**

Compute probabilities of possible outcomes for samples in X.

Parameters

**X**  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

**avg**  [array-like of shape (n_samples, n_classes)] Weighted average probability for each class per sample.

**score**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

**X**  [array-like of shape (n_samples, n_features)] Test samples.

**y**  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

**sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score**  [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(**params**)

Set the parameters of an estimator from the ensemble.
Valid parameter keys can be listed with `get_params()`. Note that you can directly set the parameters of the estimators contained in `estimators`.

**Parameters**

**params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the estimator, the individual estimator of the estimators can also be set, or can be removed by setting them to `'drop'`.

**transform** *(X)*

Return class labels or probabilities for X for each estimator.

**Parameters**

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

probabilities_or_labels

If `voting='soft' and flatten_transform=True`: returns ndarray of shape (n_classifiers, n_samples * n_classes), being class probabilities calculated by each classifier.

If `voting='soft' and flatten_transform=False`: ndarray of shape (n_classifiers, n_samples, n_classes)

If `voting='hard'`: ndarray of shape (n_samples, n_classifiers), being class labels predicted by each classifier.

Examples using `sklearn.ensemble.VotingClassifier`

- Plot the decision boundaries of a VotingClassifier
- Plot class probabilities calculated by the VotingClassifier

**7.11.16 sklearn.ensemble.VotingRegressor**

class sklearn.ensemble.VotingRegressor(**kwargs)

Prediction voting regressor for unfitted estimators.

A voting regressor is an ensemble meta-estimator that fits several base regressors, each on the whole dataset. Then it averages the individual predictions to form a final prediction.

Read more in the User Guide.

New in version 0.21.

**Parameters**

estimators [list of (str, estimator) tuples] Invoking the `fit` method on the VotingRegressor will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to 'drop' using `set_params`.

Changed in version 0.21: 'drop' is accepted. Using None was deprecated in 0.22 and support was removed in 0.24.
weights [array-like of shape (n_regressors,), default=None] Sequence of weights (float or int) to weight the occurrences of predicted values before averaging. Uses uniform weights if None.

n_jobs [int, default=None] The number of jobs to run in parallel for fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [bool, default=False] If True, the time elapsed while fitting will be printed as it is completed.

Attributes

estimators_ [list of regressors] The collection of fitted sub-estimators as defined in estimators that are not ‘drop’.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

See also:

VotingClassifier Soft Voting/Majority Rule classifier.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import VotingRegressor

>>> r1 = LinearRegression()
>>> r2 = RandomForestRegressor(n_estimators=10, random_state=1)
>>> X = np.array([[1, 1], [2, 4], [3, 9], [4, 16], [5, 25], [6, 36]])
>>> y = np.array([2, 6, 12, 20, 30, 42])
>>> er = VotingRegressor([('lr', r1), ('rf', r2)])
>>> print(er.fit(X, y).predict(X))
[ 3.3 5.7 11.8 19.7 28. 40.3]
```

Methods

```python
fit(X, y[, sample_weight]) Fit the estimators.
fit_transform(X[, y]) Return class labels or probabilities for each estimator.
get_params([deep]) Get the parameters of an estimator from the ensemble.
predict(X) Predict regression target for X.
score(X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.
set_params(**params) Set the parameters of an estimator from the ensemble.
transform(X) Return predictions for X for each estimator.
```

```python
fit (X, y, sample_weight=None)
```
Fit the estimators.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

self [object] Fitted estimator.

fit_transform(X, y=None, **fit_params)

Return class labels or probabilities for each estimator.

Return predictions for X for each estimator.

Parameters

X [{array-like, sparse matrix, dataframe} of shape (n_samples, n_features)] Input samples

y [ndarray of shape (n_samples,), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)

Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

Parameters

dep [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

predict (X)

Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples.

Returns

y [ndarray of shape (n_samples,)] The predicted values.

score (X, y, sample_weight=None)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \( \sum (y_true - y_pred)^2 \) and \( v \) is the total sum of squares \( \sum (y_true - y_true.mean())^2 \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A
A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params(**params**)**

Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`. Note that you can directly set the parameters of the estimators contained in `estimators`.

**Parameters**

- **params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the estimator, the individual estimator of the estimators can also be set, or can be removed by setting them to ‘drop’.

**transform(X)**

Return predictions for X for each estimator.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples.

**Returns**

- **predictions**: ndarray of shape (n_samples, n_classifiers) Values predicted by each regressor.

**Examples using sklearn.ensemble.VotingRegressor**

- Plot individual and voting regression predictions
7.11.17 sklearn.ensemble.HistGradientBoostingRegressor

class sklearn.ensemble.HistGradientBoostingRegressor (**kwargs)

Histogram-based Gradient Boosting Regression Tree.

This estimator is much faster than GradientBoostingRegressor for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each
split point whether samples with missing values should go to the left or right child, based on the potential gain.
When predicting, samples with missing values are assigned to the left or right child consequently. If no missing
values were encountered for a given feature during training, then samples with missing values are mapped to
whichever child has the most samples.

This implementation is inspired by LightGBM.

Note: This estimator is still experimental for now: the predictions and the API might change without any
deprecation cycle. To use it, you need to explicitly import enable_hist_gradient_boosting:

```python
>>> from sklearn.experimental import enable_hist_gradient_boosting
>>> from sklearn.ensemble import HistGradientBoostingRegressor
```

Read more in the User Guide.

New in version 0.21.

Parameters

- **loss** [{‘least_squares’, ‘least_absolute_deviation’, ‘poisson’}, default='least_squares'] The loss
  function to use in the boosting process. Note that the “least squares” and “poisson” losses
  actually implement “half least squares loss” and “half poisson deviance” to simplify the
  computation of the gradient. Furthermore, “poisson” loss internally uses a log-link and
  requires y >= 0

  Changed in version 0.23: Added option ‘poisson’.

- **learning_rate** [float, default=0.1] The learning rate, also known as shrinkage. This is used as a
  multiplicative factor for the leaves values. Use 1 for no shrinkage.

- **max_iter** [int, default=100] The maximum number of iterations of the boosting process, i.e. the
  maximum number of trees.

- **max_leaf_nodes** [int or None, default=31] The maximum number of leaves for each tree. Must
  be strictly greater than 1. If None, there is no maximum limit.

- **max_depth** [int or None, default=None] The maximum depth of each tree. The depth of a tree
  is the number of edges to go from the root to the deepest leaf. Depth isn’t constrained by
  default.

- **min_samples_leaf** [int, default=20] The minimum number of samples per leaf. For small
  datasets with less than a few hundred samples, it is recommended to lower this value since
  only very shallow trees would be built.

- **l2_regularization** [float, default=0] The L2 regularization parameter. Use 0 for no regulariza-
  tion (default).

- **max_bins** [int, default=255] The maximum number of bins to use for non-missing values. Be-
  fore training, each feature of the input array X is binned into integer-valued bins, which
  allows for a much faster training stage. Features with a small number of unique values may
use less than max_bins bins. In addition to the max_bins bins, one more bin is always reserved for missing values. Must be no larger than 255.

**monotonic_cst** [array-like of int of shape (n_features), default=None] Indicates the monotonic constraint to enforce on each feature. -1, 1 and 0 respectively correspond to a negative constraint, positive constraint and no constraint. Read more in the User Guide.

New in version 0.23.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See the Glossary.

**early_stopping** ['auto' or bool, default='auto'] If 'auto', early stopping is enabled if the sample size is larger than 10000. If True, early stopping is enabled, otherwise early stopping is disabled.

New in version 0.23.

**scoring** [str or callable or None, default='loss'] Scoring parameter to use for early stopping. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator's default scorer is used. If scoring='loss', early stopping is checked w.r.t the loss value. Only used if early stopping is performed.

**validation_fraction** [int or float or None, default=0.1] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if early stopping is performed.

**n_iter_no_change** [int, default=10] Used to determine when to “early stop”. The fitting process is stopped when none of the last n_iter_no_change scores are better than the n_iter_no_change - 1-th-to-last one, up to some tolerance. Only used if early stopping is performed.

**tol** [float or None, default=1e-7] The absolute tolerance to use when comparing scores during early stopping. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

**verbose** [int, default=0] The verbosity level. If not zero, print some information about the fitting process.

**random_state** [int, RandomState instance or None, default=None] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. Pass an int for reproducible output across multiple function calls. See Glossary.

### Attributes

**do_early_stopping** [bool] Indicates whether early stopping is used during training.

**n_iter** [int] The number of iterations as selected by early stopping, depending on the early_stopping parameter. Otherwise it corresponds to max_iter.

**n_trees_per_iteration** [int] The number of tree that are built at each iteration. For regressors, this is always 1.

**train_score** [ndarray, shape (n_iter+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. If scoring is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.
**validation_score**: [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. Empty if no early stopping or if `validation_fraction` is None.

**Examples**

```python
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_diabetes

>>> X, y = load_diabetes(return_X_y=True)
>>> est = HistGradientBoostingRegressor().fit(X, y)
>>> est.score(X, y)
0.92...
```

**fit (X, y, sample_weight=None)**

Fit the gradient boosting model.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] The input samples.
- `y` [array-like of shape (n_samples,)] Target values.
- `sample_weight` [array-like of shape (n_samples,) default=None] Weights of training data. New in version 0.23.

**Returns**

- `self` [object]  

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**predict (X)**

Predict values for X.
Parameters

X [array-like, shape (n_samples, n_features)] The input samples.

Returns

y [ndarray, shape (n_samples,)] The predicted values.

score (X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y\_true - y\_pred)^2)$ and $v$ is the total sum of squares $\sum((y\_true - y\_true.\text{mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

staged_predict (X)

Predict regression target for each iteration

This method allows monitoring (i.e. determine error on testing set) after each stage.

New in version 0.24.

Parameters

X [array-like of shape (n_samples, n_features)] The input samples.

Yields
y [generator of ndarray of shape (n_samples,)] The predicted values of the input samples, for each iteration.

- Combine predictors using stacking
- Poisson regression and non-normal loss
- Partial Dependence and Individual Conditional Expectation Plots

7.11.18 sklearn.ensemble.HistGradientBoostingClassifier

class sklearn.ensemble.HistGradientBoostingClassifier(**kwargs)

Histogram-based Gradient Boosting Classification Tree.

This estimator is much faster than GradientBoostingClassifier for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain. When predicting, samples with missing values are assigned to the left or right child consequently. If no missing values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_hist_gradient_boosting:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting
# noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

Read more in the User Guide.

New in version 0.21.

Parameters

- **loss** [{‘auto’, ‘binary_crossentropy’, ‘categorical_crossentropy’}, default=’auto’] The loss function to use in the boosting process. ‘binary_crossentropy’ (also known as logistic loss) is used for binary classification and generalizes to ‘categorical_crossentropy’ for multiclass classification. ‘auto’ will automatically choose either loss depending on the nature of the problem.

- **learning_rate** [float, default=0.1] The learning rate, also known as shrinkage. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.
max_iter [int, default=100] The maximum number of iterations of the boosting process, i.e. the maximum number of trees for binary classification. For multiclass classification, n_classes trees per iteration are built.

max_leaf_nodes [int or None, default=31] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

max_depth [int or None, default=None] The maximum depth of each tree. The depth of a tree is the number of edges to go from the root to the deepest leaf. Depth isn’t constrained by default.

min_samples_leaf [int, default=20] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

l2_regularization [float, default=0] The L2 regularization parameter. Use 0 for no regularization.

max_bins [int, default=255] The maximum number of bins to use for non-missing values. Before training, each feature of the input array X is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than max_bins bins. In addition to the max_bins bins, one more bin is always reserved for missing values. Must be no larger than 255.

monotonic_cst [array-like of int of shape (n_features), default=None] Indicates the monotonic constraint to enforce on each feature. -1, 1 and 0 respectively correspond to a negative constraint, positive constraint and no constraint. Read more in the User Guide. New in version 0.23.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See the Glossary.

early_stopping ['auto' or bool, default='auto'] If 'auto', early stopping is enabled if the sample size is larger than 10000. If True, early stopping is enabled, otherwise early stopping is disabled.

New in version 0.23.

scoring [str or callable or None, default='loss'] Scoring parameter to use for early stopping. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator’s default scorer is used. If scoring='loss', early stopping is checked w.r.t the loss value. Only used if early stopping is performed.

validation_fraction [int or float or None, default=0.1] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if early stopping is performed.

n_iter_no_change [int, default=10] Used to determine when to “early stop”. The fitting process is stopped when none of the last n_iter_no_change scores are better than the n_iter_no_change - 1-th-to-last one, up to some tolerance. Only used if early stopping is performed.

tol [float or None, default=1e-7] The absolute tolerance to use when comparing scores. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.
verbose [int, default=0] The verbosity level. If not zero, print some information about the fitting process.

random_state [int, RandomState instance or None, default=None] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

classes_ [array, shape = (n_classes,)] Class labels.

do_early_stopping_ [bool] Indicates whether early stopping is used during training.

n_iter_ [int] The number of iterations as selected by early stopping, depending on the early_stopping parameter. Otherwise it corresponds to max_iter.

n_trees_per_iteration_ [int] The number of tree that are built at each iteration. This is equal to 1 for binary classification, and to n_classes for multiclass classification.

train_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. If scoring is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

validation_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. Empty if no early stopping or if validation_fraction is None.

Examples

>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.datasets import load_iris
>>> X, y = load_iris(return_X_y=True)
>>> clf = HistGradientBoostingClassifier().fit(X, y)
>>> clf.score(X, y)
1.0

Methods

decision_function(X) Compute the decision function of X.

fit(X, y[, sample_weight]) Fit the gradient boosting model.

get_params([deep]) Get parameters for this estimator.

predict(X) Predict classes for X.

predict_proba(X) Predict class probabilities for X.

score(X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.

set_params(**params) Set the parameters of this estimator.

staged_decision_function(X) Compute decision function of X for each iteration.

staged_predict(X) Predict classes at each iteration.

staged_predict_proba(X) Predict class probabilities at each iteration.
**decision_function**(*X*)

Compute the decision function of *X*.

**Parameters**

- *X* [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- **decision** [ndarray, shape (n_samples,) or (n_samples, n_trees_per_iteration)] The raw predicted values (i.e. the sum of the trees leaves) for each sample. *n_trees_per_iteration* is equal to the number of classes in multiclass classification.

**fit**(*X*, *y*, *sample_weight=None*)

Fit the gradient boosting model.

**Parameters**

- *X* [array-like of shape (n_samples, n_features)] The input samples.
- *y* [array-like of shape (n_samples,)] Target values.
- *sample_weight* [array-like of shape (n_samples,), default=None] Weights of training data.

  New in version 0.23.

**Returns**

- **self** [object]

**get_params**(*deep=True*)

Get parameters for this estimator.

**Parameters**

- *deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict**(*X*)

Predict classes for *X*.

**Parameters**

- *X* [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- *y* [ndarray, shape (n_samples,)] The predicted classes.

**predict_proba**(*X*)

Predict class probabilities for *X*.

**Parameters**

- *X* [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- *p* [ndarray, shape (n_samples, n_classes)] The class probabilities of the input samples.

**score**(*X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**
- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**
- **params** [dict] Estimator parameters.

**Returns**
- **self** [estimator instance] Estimator instance.

**staged_decision_function**(X)
Compute decision function of X for each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] The input samples.

**Yields**
- **decision** [generator of ndarray of shape (n_samples,) or (n_samples, n_trees_per_iteration)]
  The decision function of the input samples, which corresponds to the raw values predicted from the trees of the ensemble. The classes corresponds to that in the attribute `classes_`.

**staged_predict**(X)
Predict classes at each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.

New in version 0.24.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] The input samples.

**Yields**
- **y** [generator of ndarray of shape (n_samples,)] The predicted classes of the input samples, for each iteration.

**staged_predict_proba**(X)
Predict class probabilities at each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.

**Parameters**
X [array-like of shape (n_samples, n_features)] The input samples.

Yields

y [generator of ndarray of shape (n_samples,)] The predicted class probabilities of the input samples, for each iteration.

- Release Highlights for scikit-learn 0.22

7.12 sklearn.exceptions: Exceptions and warnings

The sklearn.exceptions module includes all custom warnings and error classes used across scikit-learn.

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exceptions.ConvergenceWarning</td>
<td>Custom warning to capture convergence problems</td>
</tr>
<tr>
<td>exceptions.DataConversionWarning</td>
<td>Warning used to notify implicit data conversions happening in the code.</td>
</tr>
<tr>
<td>exceptions.DataDimensionalityWarning</td>
<td>Custom warning to notify potential issues with data dimensionality.</td>
</tr>
<tr>
<td>exceptions.EfficiencyWarning</td>
<td>Warning used to notify the user of inefficient computation.</td>
</tr>
<tr>
<td>exceptions.FitFailedWarning</td>
<td>Warning class used if there is an error while fitting the estimator.</td>
</tr>
<tr>
<td>exceptions.NotFittedError</td>
<td>Exception class to raise if estimator is used before fitting.</td>
</tr>
<tr>
<td>exceptions.UndefineMetricWarning</td>
<td>Warning used when the metric is invalid.</td>
</tr>
</tbody>
</table>

7.12.1 sklearn.exceptions.ConvergenceWarning

class sklearn.exceptions.ConvergenceWarning

    Custom warning to capture convergence problems

    Changed in version 0.18: Moved from sklearn.utils.

    Attributes

    args
Methods

```python
with_traceback
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.
```
7.12.3 sklearn.exceptions.DataDimensionalityWarning

class sklearn.exceptions.DataDimensionalityWarning
Custom warning to notify potential issues with data dimensionality.

For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

Changed in version 0.18: Moved from sklearn.utils.

Attributes

args

Methods

with_traceback
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.

with_traceback()    
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.

7.12.4 sklearn.exceptions.EfficiencyWarning

class sklearn.exceptions.EfficiencyWarning
Warning used to notify the user of inefficient computation.

This warning notifies the user that the efficiency may not be optimal due to some reason which may be included as a part of the warning message. This may be subclassed into a more specific Warning class.

New in version 0.18.

Attributes

args

Methods

with_traceback
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.

with_traceback()
    Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.
7.12.5 sklearn.exceptions.FitFailedWarning

class sklearn.exceptions.FitFailedWarning

Warning class used if there is an error while fitting the estimator.

This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation helper function cross_val_score to warn when there is an error while fitting the estimator.

Changed in version 0.18: Moved from sklearn.cross_validation.

Attributes

args

Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.6 sklearn.exceptions.NotFittedError

class sklearn.exceptions.NotFittedError

Exception class to raise if estimator is used before fitting.

This class inherits from both ValueError and AttributeError to help with exception handling and backward compatibility.

Attributes

args

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...    LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...    print(repr(e))
NotFittedError("This LinearSVC instance is not fitted yet. Call 'fit' with appropriate arguments before using this estimator.")
```

Changed in version 0.18: Moved from sklearn.utils.validation.
Methods

**with_traceback**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

**with_traceback()**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.7 sklearn.exceptions.UndefinedMetricWarning

class sklearn.exceptions.UndefinedMetricWarning

Warning used when the metric is invalid

Changed in version 0.18: Moved from sklearn.base.

Attributes

args

Methods

**with_traceback**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

**with_traceback()**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.13 sklearn.experimental: Experimental

The sklearn.experimental module provides importable modules that enable the use of experimental features or estimators.

The features and estimators that are experimental aren’t subject to deprecation cycles. Use them at your own risks!

| experimental.enable_hist_gradient_boost | Enables histogram-based gradient boosting estimators. |
| experimental.enable_iterative_imputer | Enables IterativeImputer |
| experimental.enable_halving_search_cv   | Enables Successive Halving search-estimators |

7.13.1 sklearn.experimental.enable_hist_gradient_boosting

Enables histogram-based gradient boosting estimators.

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the HistGradientBoostingClassifier and HistGradientBoostingRegressor as attributes of the ensemble module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> # now you can import normally from ensemble
```
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.ensemble import HistGradientBoostingRegressor

The # noqa comment comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.

### 7.13.2 sklearn.experimental.enable_iterative_imputer

Enables IterativeImputer

The API and results of this estimator might change without any deprecation cycle.

Importing this file dynamically sets `IterativeImputer` as an attribute of the impute module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer
>>> # now you can import normally from impute
>>> from sklearn.impute import IterativeImputer
```

### 7.13.3 sklearn.experimental.enable_halving_search_cv

Enables Successive Halving search-estimators

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the `HalvingRandomSearchCV` and `HalvingGridSearchCV` as attributes of the `model_selection` module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_halving_search_cv
>>> # now you can import normally from model_selection
>>> from sklearn.model_selection import HalvingRandomSearchCV
>>> from sklearn.model_selection import HalvingGridSearchCV
```

The # noqa comment comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.

### 7.14 sklearn.feature_extraction: Feature Extraction

The `sklearn.feature_extraction` module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

**User guide:** See the `Feature extraction` section for further details.

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DictVectorizer(**kwargs)</td>
<td>Transforms lists of feature-value mappings to vectors.</td>
</tr>
<tr>
<td>FeatureHasher(**kwargs)</td>
<td>Implements feature hashing, aka the hashing trick.</td>
</tr>
</tbody>
</table>
7.14.1 sklearn.feature_extraction.DictVectorizer

class sklearn.feature_extraction.DictVectorizer(**kwargs)

Transforms lists of feature-value mappings to vectors.

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or scipy.sparse matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature “f” that can take on the values “ham” and “spam” will become two features in the output, one signifying “f=ham”, the other “f=spam”.

If a feature value is a sequence or set of strings, this transformer will iterate over the values and will count the occurrences of each string value.

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as int or iterables of strings, the DictVectorizer can be followed by OneHotEncoder to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the User Guide.

Parameters

dtype [dtype, default=np.float64] The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.

separator [str, default=”=”] Separator string used when constructing new features for one-hot coding.

sparse [bool, default=True] Whether transform should produce scipy.sparse matrices.

sort [bool, default=True] Whether feature_names_ and vocabulary_ should be sorted when fitting.

Attributes

vocabulary_ [dict] A dictionary mapping feature names to feature indices.

feature_names_ [list] A list of length n_features containing the feature names (e.g., “f=ham” and “f=spam”).

See also:

FeatureHasher Performs vectorization using only a hash function.

sklearn.preprocessing.OrdinalEncoder Handles nominal/categorical features encoded as columns of arbitrary data types.

Examples

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> X
array([[2., 0., 1.],
       [0., 1., 3.]])
>>> v.inverse_transform(X) == [{'bar': 2.0, 'foo': 1.0},
(continues on next page)```
Methods

<table>

<tr>
<td>transform(X)</td>
<td>Transform feature-&gt;value dicts to array or sparse matrix.</td>
</tr>
</tbody>
</table>

**fit (X, y=None)**

Learn a list of feature name -> indices mappings.

**Parameters**

- X  [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).
  
  Changed in version 0.24: Accepts multiple string values for one categorical feature.

- y  [(ignored)]

**Returns**

- self

**fit_transform (X, y=None)**

Learn a list of feature name -> indices mappings and transform X.

Like fit(X) followed by transform(X), but does not require materializing X in memory.

**Parameters**

- X  [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).
  
  Changed in version 0.24: Accepts multiple string values for one categorical feature.

- y  [(ignored)]

**Returns**

- Xa  [array, sparse matrix]] Feature vectors; always 2-d.

**get_feature_names ()**

Returns a list of feature names, ordered by their indices.
If one-of-K coding is applied to categorical features, this will include the constructed feature names but not the original ones.

**get_params** *(deep=True)*
- Get parameters for this estimator.
  
  **Parameters**
  - `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
  
  **Returns**
  - `params` [dict] Parameter names mapped to their values.

**inverse_transform** *(X, dict_type=<class 'dict'>)*
- Transform array or sparse matrix X back to feature mappings.
  - X must have been produced by this DictVectorizer’s transform or fit_transform method; it may only have passed through transformers that preserve the number of features and their order.
  - In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than the original ones.

  **Parameters**
  - `X` [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample matrix.
  - `dict_type` [type, default=dict] Constructor for feature mappings. Must conform to the collections.Mapping API.

  **Returns**
  - `D` [list of dict_type objects of shape (n_samples,)] Feature mappings for the samples in X.

**restrict** *(support, indices=False)*
- Restrict the features to those in support using feature selection.
  - This function modifies the estimator in-place.

  **Parameters**
  - `support` [array-like] Boolean mask or list of indices (as returned by the get_support member of feature selectors).
  - `indices` [bool, default=False] Whether support is a list of indices.

  **Returns**
  - `self`

**Examples**

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> v = DictVectorizer()
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> support = SelectKBest(chi2, k=2).fit(X, [0, 1])
>>> v.get_feature_names()  # doctest: +NORMALIZE_WHITESPACE
['bar', 'baz', 'foo']
>>> v.restrict(support.get_support())
```

(continues on next page)
```python
>>> v.get_feature_names()
['bar', 'foo']
```

**set_params(***params*)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>_<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform(X)**

Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or fit_transform will be silently ignored.

**Parameters**

X [Mapping or iterable over Mappings of shape (n_samples,)] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

**Returns**

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

**Examples using sklearn.feature_extraction.DictVectorizer**

- Column Transformer with Heterogeneous Data Sources
- FeatureHasher and DictVectorizer Comparison

### 7.14.2 sklearn.feature_extraction.FeatureHasher

**class** sklearn.feature_extraction.FeatureHasher(**kwargs**)

Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into scipy.sparse matrices, using a hash function to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version of Murmurhash3.

Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to DictVectorizer and CountVectorizer, intended for large-scale (online) learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the User Guide.

New in version 0.13.

**Parameters**
**n_features** [int, default=2**20] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

**input_type** [[“dict”, “pair”, “string”], default=”dict”] Either “dict” (the default) to accept dictionaries over (feature_name, value); “pair” to accept pairs of (feature_name, value); or “string” to accept single strings. feature_name should be a string, while value should be a number. In the case of “string”, a value of 1 is implied. The feature_name is hashed to find the appropriate column for the feature. The value’s sign might be flipped in the output (but see non_negative, below).

**dtype** [numpym dtype, default=np.float64] The type of feature values. Passed to scipy.sparse matrix constructors as the dtype argument. Do not set this to bool, np.boolean or any unsigned integer type.

**alternate_sign** [bool, default=True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

.. versionchanged:: 0.19 alternate_sign replaces the now deprecated non_negative parameter.

See also:

**DictVectorizer** Vectorizes string-valued features using a hash table.

**sklearn.preprocessing.OneHotEncoder** Handles nominal/categorical features.

### Examples

```python
>>> from sklearn.feature_extraction import FeatureHasher
>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4},{'dog': 2, 'run': 5}]
>>> f = h.transform(D)
>>> f.toarray()
array([[ 0., 0., -4., -1., 0., 0., 0., 0., 0., 2.],
[ 0., 0., 0., -2., -5., 0., 0., 0., 0., 0.]])
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fit</strong>([X, y])</td>
<td>No-op.</td>
</tr>
<tr>
<td><strong>fit_transform</strong>([X, y])</td>
<td>Fit to data, then transform it.</td>
</tr>
<tr>
<td><strong>get_params</strong>([deep])</td>
<td>Get parameters for this estimator.</td>

<tr>
<td><strong>transform</strong>(raw_X)</td>
<td>Transform a sequence of instances to a scipy.sparse matrix.</td>
</tr>
</tbody>
</table>

**fit** (X=None, y=None)

No-op.

This method doesn’t do anything. It exists purely for compatibility with the scikit-learn transformer API.

#### Parameters

- **X** [ndarray]
Returns

self [FeatureHasher]

**fit_transform** (*X, y=None, **fit_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit_params* and returns a transformed version of *X*.

Parameters

*X* [array-like of shape (n_samples, n_features)] Input samples.

*y* [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

*X_new* [ndarray array of shape (n_samples, n_features)] Transformed array.

**get_params** (*deep=True*)

Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**set_params** (**params**) Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

**transform** (*raw_X*) Transform a sequence of instances to a scipy.sparse matrix.

Parameters

*raw_X* [iterable over iterable over raw features, length = n_samples] Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the input_type constructor argument) which will be hashed. *raw_X* need not support the len function, so it can be the result of a generator; n_samples is determined on the fly.

Returns

*X* [sparse matrix of shape (n_samples, n_features)] Feature matrix, for use with estimators or further transformers.
Examples using `sklearn.feature_extraction.FeatureHasher`

- FeatureHasher and DictVectorizer Comparison

### 7.14.3 From images

The `sklearn.feature_extraction.image` submodule gathers utilities to extract features from images.

</tbody>
</table>

#### sklearn.feature_extraction.image.extract_patches_2d

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the User Guide.

**Parameters**

- `image` [ndarray of shape (image_height, image_width) or (image_height, image_width, n_channels)] The original image data. For color images, the last dimension specifies the channel: a RGB image would have `n_channels=3`.
- `patch_size` [tuple of int (patch_height, patch_width)] The dimensions of one patch.
- `max_patches` [int or float, default=None] The maximum number of patches to extract. If `max_patches` is a float between 0 and 1, it is taken to be a proportion of the total number of patches.
- `random_state` [int, RandomState instance, default=None] Determines the random number generator used for random sampling when `max_patches` is not None. Use an int to make the randomness deterministic. See Glossary.

**Returns**

- `patches` [array of shape (n_patches, patch_height, patch_width) or (n_patches, patch_height, patch_width, n_channels)] The collection of patches extracted from the image, where `n_patches` is either `max_patches` or the total number of patches that can be extracted.
Examples

```python
>>> from sklearn.datasets import load_sample_image
>>> from sklearn.feature_extraction import image

# Use the array data from the first image in this dataset:
>>> one_image = load_sample_image("china.jpg")
>>> print('Image shape: {}\n'.format(one_image.shape))
Image shape: (427, 640, 3)

>>> patches = image.extract_patches_2d(one_image, (2, 2))
>>> print('Patches shape: {}\n'.format(patches.shape))
Patches shape: (272214, 2, 2, 3)

# Here are just two of these patches:
>>> print(patches[1])
[[[174 201 231]
  [174 201 231]]
[[173 200 230]
  [173 200 230]]]

>>> print(patches[800])
[[[187 214 243]
  [188 215 244]]
[[187 214 243]
  [188 215 244]]]```
Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in np.asarray to avoid type issues.

```
sklearn.feature_extraction.image.img_to_graph
```

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

Read more in the User Guide.

Parameters

- `img` [ndarray of shape (height, width) or (height, width, channel)] 2D or 3D image.
- `mask` [ndarray of shape (height, width) or (height, width, channel), dtype=bool, default=None] An optional mask of the image, to consider only part of the pixels.
- `return_as` [np.ndarray or a sparse matrix class, default=sparse.coo_matrix] The class to use to build the returned adjacency matrix.
- `dtype` [dtype, default=None] The data of the returned sparse matrix. By default it is the dtype of img

Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in np.asarray to avoid type issues.

```
sklearn.feature_extraction.image.reconstruct_from_patches_2d
```

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

Read more in the User Guide.

Parameters

- `patches` [ndarray of shape (n_patches, patch_height, patch_width) or (n_patches, patch_height, patch_width, n_channels)] The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have n_channels=3.
- `image_size` [tuple of int (image_height, image_width) or (image_height, image_width, n_channels)] The size of the image that will be reconstructed.

Returns
image  [ndarray of shape image_size] The reconstructed image.

Examples using sklearn.feature_extraction.image.reconstruct_from_patches_2d

- Image denoising using dictionary learning

sklearn.feature_extraction.image.PatchExtractor

class sklearn.feature_extraction.image.PatchExtractor(**kwargs)
Extracts patches from a collection of images

Read more in the User Guide.

New in version 0.9.

Parameters

patch_size  [tuple of int (patch_height, patch_width), default=None] The dimensions of one patch.

max_patches  [int or float, default=None] The maximum number of patches per image to extract. If max_patches is a float in (0, 1), it is taken to mean a proportion of the total number of patches.

random_state  [int, RandomState instance, default=None] Determines the random number generator used for random sampling when max_patches is not None. Use an int to make the randomness deterministic. See Glossary.

Examples

```python
>>> from sklearn.datasets import load_sample_images
>>> from sklearn.feature_extraction import image

>>> # Use the array data from the second image in this dataset:
>>> X = load_sample_images().images[1]

>>> print('Image shape: {0}'.format(X.shape))
Image shape: (427, 640, 3)

>>> pe = image.PatchExtractor(patch_size=(2, 2))
>>> pe_fit = pe.fit(X)
>>> pe_trans = pe.transform(X)

>>> print('Patches shape: {0}'.format(pe_trans.shape))
Patches shape: (545706, 2, 2)
```

Methods

*fit*(X[, y])  Do nothing and return the estimator unchanged.

*get_params*(deep)  Get parameters for this estimator.

*set_params*(**params)  Set the parameters of this estimator.

*transform*(X)  Transforms the image samples in X into a matrix of patch data.

*fit*  Do nothing and return the estimator unchanged.
This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform**(X)

Transforms the image samples in X into a matrix of patch data.

**Parameters**

- **X** [ndarray of shape (n_samples, image_height, image_width) or (n_samples, image_height, image_width, n_channels)] Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have n_channels=3.

**Returns**

- **patches** [array of shape (n_patches, patch_height, patch_width) or (n_patches, patch_height, patch_width, n_channels)] The collection of patches extracted from the images, where n_patches is either n_samples \* max_patches or the total number of patches that can be extracted.

### 7.14.4 From text

The `sklearn.feature_extraction.text` submodule gathers utilities to build feature vectors from text documents.

| `feature_extraction.text.CountVectorizer(**kwargs)` | Convert a collection of text documents to a matrix of token counts |
| `feature_extraction.text.HashingVectorizer(...)` | Convert a collection of text documents to a matrix of token occurrences |
| `feature_extraction.text.TfidfTransformer(...)` | Transform a count matrix to a normalized tf or tf-idf representation |

continues on next page
Table 105 – continued from previous page

| feature_extraction.text.TfidfVectorizer(**kwargs) | Convert a collection of raw documents to a matrix of TF-IDF features. |

**sklearn.feature_extraction.text.CountVectorizer**

class sklearn.feature_extraction.text.CountVectorizer(**kwargs)

Convert a collection of text documents to a matrix of token counts

This implementation produces a sparse representation of the counts using scipy.sparse.csr_matrix.

If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data.

Read more in the User Guide.

**Parameters**

- **input** [string {'filename', 'file', 'content'}, default='content'] If ‘filename’, the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

  If ‘file’, the sequence items must have a ‘read’ method (file-like object) that is called to fetch the bytes in memory.

  Otherwise the input is expected to be a sequence of items that can be of type string or byte.

- **encoding** [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

- **decode_error** [{'strict', 'ignore', 'replace'}, default='strict'] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is ‘strict’, meaning that a UnicodeDecodeError will be raised. Other values are ‘ignore’ and ‘replace’.

- **strip_accents** [{‘ascii’, ‘unicode’}, default=None] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

  Both ‘ascii’ and ‘unicode’ use NFKD normalization from unicodedata.normalize.

- **lowercase** [bool, default=True] Convert all characters to lowercase before tokenizing.

- **preprocessor** [callable, default=None] Override the preprocessing (strip_accents and lowercase) stage while preserving the tokenizing and n-grams generation steps. Only applies if analyzer is not callable.

- **tokenizer** [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

- **stop_words** [string {'english'}, list, default=None] If ‘english’, a built-in stop word list for English is used. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

  If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.

  If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.
**token_pattern** [str, default=r’(?u)\b\w\w+\b’] Regular expression denoting what constitutes a “token”, only used if `analyzer == 'word'`. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**ngram_range** [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different word n-grams or char n-grams to be extracted. All values of n such such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if `analyzer` is not callable.

**analyzer** [‘word’, ‘char’, ‘char_wb’] or callable, default=‘word’ Whether the feature should be made of word n-gram or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**max_df** [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min_df** [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max_features** [int, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, default=None] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

**binary** [bool, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**dtype** [type, default=np.int64] Type of the matrix returned by fit_transform() or transform().

**Attributes**

**vocabulary** [dict] A mapping of terms to feature indices.

**fixed_vocabulary**: boolean True if a fixed vocabulary of term to indices mapping is provided by the user

**stop_words** [set] Terms that were ignored because they either:

- occurred in too many documents (`max_df`)
- occurred in too few documents (`min_df`)
- were cut off by feature selection (`max_features`).

This is only available if no vocabulary was given.
See also:

*HashingVectorizer, TfidfVectorizer*

Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using `delattr` or set to `None` before pickling.

Examples

```python
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> corpus = [
...   'This is the first document.',
...   'This document is the second document.',
...   'And this is the third one.',
...   'Is this the first document?',
...]
>>> vectorizer = CountVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.toarray())
[[0 1 1 0 0 1 0 1 0 1]
 [0 2 0 1 0 1 0 1 0 1]
 [1 0 0 1 1 0 1 1 1]
 [0 1 1 1 0 0 1 0 1]]
>>> vectorizer2 = CountVectorizer(analyzer='word', ngram_range=(2, 2))
>>> X2 = vectorizer2.fit_transform(corpus)
>>> print(vectorizer2.get_feature_names())
['and this', 'document is', 'first document', 'is the', 'is this',
 'second document', 'the first', 'the second', 'the third', 'third one',
 'this document', 'this is', 'this the']
>>> print(X2.toarray())
[[0 0 1 1 0 1 0 0 0 1 0]
 [0 1 0 1 0 1 0 1 0 1 0]
 [1 0 0 1 0 0 0 1 1 0 1]
 [0 0 1 0 1 0 1 0 0 0 1]]
```

**build_analyzer()**

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

- **analyzer:** callable A function to handle preprocessing, tokenization and n-grams generation.

**build_preprocessor()**

Return a function to preprocess the text before tokenization.

Returns

- **preprocessor:** callable A function to preprocess the text before tokenization.

**build_tokenizer()**

Return a function that splits a string into a sequence of tokens.

Returns

- **tokenizer:** callable A function to split a string into a sequence of tokens.

**decode**(doc)

Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

- **doc:** [str] The string to decode.

Returns

- **doc:** str A string of unicode symbols.

**fit**(raw_documents, y=None)

Learn a vocabulary dictionary of all tokens in the raw documents.

Parameters

- **raw_documents:** [iterable] An iterable which yields either str, unicode or file objects.

Returns

- **self**

**fit_transform**(raw_documents, y=None)

Learn the vocabulary dictionary and return document-term matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters
raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

X [array of shape (n_samples, n_features)] Document-term matrix.

get_feature_names ()
Array mapping from feature integer indices to feature name.

Returns

feature_names [list] A list of feature names.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_stop_words ()
Build or fetch the effective stop words list.

Returns

stop_words: list or None A list of stop words.

inverse_transform (X)
Return terms per document with nonzero entries in X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

Returns

X_inv [list of arrays of shape (n_samples,)] List of arrays of terms.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component of
a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (raw_documents)
Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to
the constructor.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.
Returns

X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

Examples using `sklearn.feature_extraction.text.CountVectorizer`

- Sample pipeline for text feature extraction and evaluation

`sklearn.feature_extraction.text.HashingVectorizer`

```python
class sklearn.feature_extraction.text.HashingVectorizer(**kwargs)

Convert a collection of text documents to a matrix of token occurrences

It turns a collection of text documents into a scipy.sparse matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if norm='l1' or projected on the euclidean unit sphere if norm='l2'.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

- it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
- it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
- it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a CountVectorizer with an in-memory vocabulary):

- there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
- there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if n_features is large enough (e.g. 2 ** 18 for text classification problems).
- no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the User Guide.

Parameters

- **input** [string {'filename', 'file', 'content'}, default='content'] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.
  
  If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.
  
  Otherwise the input is expected to be a sequence of items that can be of type string or byte.

- **encoding** [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

- **decode_error** [{‘strict’, ‘ignore’, ‘replace’}, default='strict'] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is ‘strict’, meaning that a UnicodeDecodeError will be raised. Other values are ‘ignore’ and ‘replace’.

7.14. `sklearn.feature_extraction`: Feature Extraction
strip_accents  [{‘ascii’, ‘unicode’}, default=None] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have a direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from `unicodedata.normalize`.

lowercase  [bool, default=True] Convert all characters to lowercase before tokenizing.

preprocessor  [callable, default=None] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if analyzer is not callable.

tokenizer  [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

stop_words  [string {‘english’}, list, default=None] If ‘english’, a built-in stop word list for English is used. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.

token_pattern  [str, default=r"(?u)\b\w\w+\b"] Regular expression denoting what constitutes a “token”, only used if analyzer == 'word'. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

ngram_range  [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if analyzer is not callable.

analyzer  [{‘word’, ‘char’, ‘char_wb’} or callable, default=’word’] Whether the feature should be made of word or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if input is filename or file, the data is first read from the file and then passed to the given callable analyzer.

n_features  [int, default=(2 ** 20)] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

binary  [bool, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

norm  [{‘l1’, ‘l2’}, default=’l2’] Norm used to normalize term vectors. None for no normalization.

alternate_sign  [bool, default=True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

New in version 0.19.

dtype  [type, default=np.float64] Type of the matrix returned by fit_transform() or transform().

</table>

**build_analyzer()**
Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

- **analyzer**: callable A function to handle preprocessing, tokenization and n-grams generation.

**build_preprocessor()**
Return a function to preprocess the text before tokenization.

Returns

- **preprocessor**: callable A function to preprocess the text before tokenization.
Returns

tokenizer: callable  A function to split a string into a sequence of tokens.

decode (doc)
Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

doc  [str] The string to decode.

Returns

doc: str  A string of unicode symbols.

fit (X, y=\text{None})
Does nothing: this transformer is stateless.

Parameters

X  [ndarray of shape [n_samples, n_features]] Training data.

fit_transform (X, y=\text{None})
Transform a sequence of documents to a document-term matrix.

Parameters

X  [iterable over raw text documents, length = n_samples] Samples. Each sample must be a
text document (either bytes or unicode strings, file name or file object depending on the
constructor argument) which will be tokenized and hashed.

y  [any] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

X  [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dee [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

get_stop_words ()
Build or fetch the effective stop words list.

Returns

stop_words: list or None  A list of stop words.

partial_fit (X, y=\text{None})
Does nothing: this transformer is stateless.

This method is just there to mark the fact that this transformer can work in a streaming setup.

Parameters

X  [ndarray of shape [n_samples, n_features]] Training data.
set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Transform a sequence of documents to a document-term matrix.

Parameters

X [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

Returns

X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

Examples using sklearn.feature_extraction.text.HashingVectorizer

- Out-of-core classification of text documents
- Clustering text documents using k-means
- Classification of text documents using sparse features

sklearn.feature_extraction.text.TfidfTransformer

class sklearn.feature_extraction.text.TfidfTransformer (**kwargs)

Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.

The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.

The formula that is used to compute the tf-idf for a term t of a document d in a document set is tf-idf(t, d) = tf(t, d) * idf(t), and the idf is computed as idf(t) = log [ n / df(t) ] + 1 (if smooth_idf=False), where n is the total number of documents in the document set and df(t) is the document frequency of t; the document frequency is the number of documents in the document set that contain the term t. The effect of adding “1” to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored. (Note that the idf formula above differs from the standard textbook notation that defines the idf as idf(t) = log [ n / (df(t) + 1) ].

If smooth_idf=True (the default), the constant “1” is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions: idf(t) = log [ (1 + n) / (1 + df(t)) ] + 1.
Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

Tf is "n" (natural) by default, "l" (logarithmic) when `sublinear_tf=True`. Idf is "t" when `use_idf` is given, "n" (none) otherwise. Normalization is "c" (cosine) when `norm='l2'`, "n" (none) when `norm=None`.

Read more in the User Guide.

**Parameters**

- `norm` [{'l1', 'l2'}, default='l2'] Each output row will have unit norm, either: * 'l2': Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * 'l1': Sum of absolute values of vector elements is 1. See `preprocessing.normalize`

- `smooth_idf` [bool, default=True] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

- `sublinear_tf` [bool, default=False] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

**Attributes**

- `idf_` [array of shape (n_features)] The inverse document frequency (IDF) vector; only defined if `use_idf` is True. New in version 0.20.

[Yates2011], [MRS2008]

**Examples**

```python
>>> from sklearn.feature_extraction.text import TfidfTransformer
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> from sklearn.pipeline import Pipeline
>>> import numpy as np

>>> corpus = ['this is the first document','this document is the second document','and this is the third one','is this the first document']

>>> vocabulary = ['this', 'document', 'first', 'is', 'second', 'the','and', 'one']

>>> pipe = Pipeline([('count', CountVectorizer(vocabulary=vocabulary)),
...                   ('tfid', TfidfTransformer())]).fit(corpus)

>>> pipe['count'].transform(corpus).toarray()
array([[1, 1, 1, 1, 0, 1, 0, 0],
       [1, 2, 0, 1, 1, 1, 0, 0],
       [1, 0, 0, 1, 0, 1, 1, 1],
       [1, 1, 1, 1, 0, 1, 0, 0]])

>>> pipe['tfid'].idf_
array([1.        , 1.22314355, 1.51082562, 1.        ,
       1.91629073, 1.        , 1.91629073, 1.91629073])

>>> pipe.transform(corpus).shape
(4, 8)
```

**fit** *(X, y=None)*

Learn the idf vector (global term weights).

**Parameters**

- **X** [sparse matrix of shape n_samples, n_features] A matrix of term/token counts.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**set_params**(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** *(X, copy=True)*

Transform a count matrix to a tf or tf-idf representation.
Parameters

X [sparse matrix of (n_samples, n_features)] a matrix of term/token counts

copy [bool, default=True] Whether to copy X and operate on the copy or perform in-place operations.

Returns

vectors [sparse matrix of shape (n_samples, n_features)]

Examples using sklearn.feature_extraction.text.TfidfTransformer

• Sample pipeline for text feature extraction and evaluation

sklearn.feature_extraction.text.TfidfVectorizer

class sklearn.feature_extraction.text.TfidfVectorizer(**kwargs)

Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to CountVectorizer followed by TfidfTransformer.

Read more in the User Guide.

Parameters

input [{'filename', 'file', 'content'}, default='content'] If ‘filename’, the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If ‘file’, the sequence items must have a ‘read’ method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

tokenizer [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer is not callable.

tokenizer [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.
**analyzer** [‘word’, ‘char’, ‘char_wb’) or callable, default=‘word’) Whether the feature should be made of word or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if input is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**stop_words** [‘english’, list, default=None] If a string, it is passed to _check_stop_list and the appropriate stop list is returned. ‘english’ is currently the only supported string value. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

**token_pattern** [str, default=r'(?u)\w\w+\b'] Regular expression denoting what constitutes a “token”, only used if analyzer == 'word'. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**ngram_range** [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if analyzer is not callable.

**max_df** [float or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float in range [0.0, 1.0], the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min_df** [float or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float in range [0.0, 1.0], the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max_features** [int, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, default=None] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

**binary** [bool, default=False] If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set idf and normalization to False to get 0/1 outputs).

**dtype** [dtype, default=float64] Type of the matrix returned by fit_transform() or transform().

**norm** [{‘l1’, ‘l2’}, default=‘l2’] Each output row will have unit norm, either: * ‘l2’: Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot
product when l2 norm has been applied. * ‘l1’: Sum of absolute values of vector elements
is 1. See preprocessing.normalize.

smooth_idf [bool, default=True] Smooth idf weights by adding one to document frequencies, as
if an extra document was seen containing every term in the collection exactly once. Prevents
zero divisions.

sublinear_tf [bool, default=False] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

Attributes

vocabulary_[dict] A mapping of terms to feature indices.

fixed_vocabulary_: bool True if a fixed vocabulary of term to indices mapping is provided by
the user

idf_ [array of shape (n_features,)] The inverse document frequency (IDF) vector; only defined
if use_idf is True.

stop_words_[set] Terms that were ignored because they either:
• occurred in too many documents (max_df)
• occurred in too few documents (min_df)
• were cut off by feature selection (max_features).
This is only available if no vocabulary was given.

See also:

CountVectorizer Transforms text into a sparse matrix of n-gram counts.

TfidfTransformer Performs the TF-IDF transformation from a provided matrix of counts.

Notes

The stop_words_ attribute can get large and increase the model size when pickling. This attribute is provided
only for introspection and can be safely removed using delattr or set to None before pickling.

Examples

```python
>>> from sklearn.feature_extraction.text import TfidfVectorizer
>>> corpus = [
... 'This is the first document.',
... 'This document is the second document.',
... 'And this is the third one.',
... 'Is this the first document?',
... ]
>>> vectorizer = TfidfVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.shape)
(4, 9)
```

**build_analyzer()**

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

- `analyzer: callable` A function to handle preprocessing, tokenization and n-grams generation.

**build_preprocessor()**

Return a function to preprocess the text before tokenization.

Returns

- `preprocessor: callable` A function to preprocess the text before tokenization.

**build_tokenizer()**

Return a function that splits a string into a sequence of tokens.

Returns

- `tokenizer: callable` A function to split a string into a sequence of tokens.

**decode(doc)**

Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

- `doc` [str] The string to decode.

Returns

- `doc: str` A string of unicode symbols.

**fit(raw_documents, y=None)**

Learn vocabulary and idf from training set.

Parameters
raw_documents [iterable] An iterable which yields either str, unicode or file objects.

y [None] This parameter is not needed to compute tfidf.

Returns

self [object] Fitted vectorizer.

**fit_transform**(raw_documents, y=None)

Learn vocabulary and idf, return document-term matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

y [None] This parameter is ignored.

Returns

X [sparse matrix of (n_samples, n_features)] Tf-idf-weighted document-term matrix.

**get_feature_names**()

Array mapping from feature integer indices to feature name.

Returns

feature_names [list] A list of feature names.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**get_stop_words**()

Build or fetch the effective stop words list.

Returns

stop_words: list or None A list of stop words.

**inverse_transform**(X)

Return terms per document with nonzero entries in X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

Returns

X_inv [list of arrays of shape (n_samples,)] List of arrays of terms.

**set_params**(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** *(raw_documents)*

Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit_transform).

**Parameters**

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

**Returns**

X [sparse matrix of (n_samples, n_features)] Tf-idf-weighted document-term matrix.

Examples using sklearn.feature_extraction.text.TfidfVectorizer

• Biclustering documents with the Spectral Co-clustering algorithm
• Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
• Column Transformer with Heterogeneous Data Sources
• Clustering text documents using k-means
• Classification of text documents using sparse features

7.15 sklearn.feature_selection: Feature Selection

The sklearn.feature_selection module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

**User guide:** See the Feature selection section for further details.

### 7.15.1 sklearn.feature_selection.GenericUnivariateSelect

class sklearn.feature_selection.GenericUnivariateSelect(**kwargs)

Univariate feature selector with configurable strategy.

Read more in the [User Guide](#).

**Parameters**

- **score_func** [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). For modes ‘percentile’ or ‘kbest’ it can return a single array scores.
- **param** [float or int depending on the feature selection mode, default=1e-5] Parameter of the corresponding mode.

**Attributes**

- **scores_** [array-like of shape (n_features,)] Scores of features.
- **pvalues_** [array-like of shape (n_features,)] p-values of feature scores, None if score_func returned scores only.

See also:

- **f_classif** ANOVA F-value between label/feature for classification tasks.
- **mutual_info_classif** Mutual information for a discrete target.
- **chi2** Chi-squared stats of non-negative features for classification tasks.
- **f_regression** F-value between label/feature for regression tasks.
- **mutual_info_regression** Mutual information for a continuous target.
- **SelectPercentile** Select features based on percentile of the highest scores.
- **SelectKBest** Select features based on the k highest scores.
- **SelectFpr** Select features based on a false positive rate test.
- **SelectFdr** Select features based on an estimated false discovery rate.
- **SelectFwe** Select features based on family-wise error rate.

**Examples**

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import GenericUnivariateSelect, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> transformer = GenericUnivariateSelect(chi2, mode='k_best', param=20)
>>> X_new = transformer.fit_transform(X, y)
```

</tr>
</tbody>
</table>

**fit (X, y)**  
Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- self [object]

**fit_transform (X, y=None, **fit_params)**  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

****fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params (deep=True)**  
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.
get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters
indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns
support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [ # input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [ # output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters
X [array of shape [n_samples, n_selected_features]] The input samples.

Returns
X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.

Parameters
X [array of shape [n_samples, n_features]] The input samples.

Returns
X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.
7.15.2 sklearn.feature_selection.SelectPercentile

class sklearn.feature_selection.SelectPercentile(**kwargs)
    Select features according to a percentile of the highest scores.

    Read more in the User Guide.

    Parameters

    score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a
    pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below
    “See Also”). The default function only works with classification tasks.

    New in version 0.18.

    percentile [int, default=10] Percent of features to keep.

    Attributes

    scores_ [array-like of shape (n_features,)] Scores of features.

    pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if score_func
    returned only scores.

    See also:

    f_classif ANOVA F-value between label/feature for classification tasks.

    mutual_info_classif Mutual information for a discrete target.

</tr>
</tbody>
</table>

**Methods**

```python
fit(X, y)
Run score function on (X, y) and get the appropriate features.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

- **self** [object]

```
```
Returns

**support** [array] An index that selects the retained features from a feature vector. If **indices** is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If **indices** is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** (*X*)
Reverse the transformation operation

**Parameters**

*X* [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

*X_r* [array of shape [n_samples, n_original_features]] *X* with columns of zeros inserted where features would have been removed by **transform**.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (*X*)
Reduce *X* to the selected features.

**Parameters**

*X* [array of shape [n_samples, n_features]] The input samples.

**Returns**

*X_r* [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

**Examples using sklearn.feature_selection.SelectPercentile**

- *Feature agglomeration vs. univariate selection*
- *SVM-Anova: SVM with univariate feature selection*
7.15.3 sklearn.feature_selection.SelectKBest

class sklearn.feature_selection.SelectKBest(**kwargs)

Select features according to the k highest scores.

Read more in the User Guide.

Parameters

score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below “See Also”). The default function only works with classification tasks.

New in version 0.18.

k [int or “all”, default=10] Number of top features to select. The “all” option bypasses selection, for use in a parameter search.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if score_func returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectKBest(chi2, k=20).fit_transform(X, y)
>>> X_new.shape
(1797, 20)
```

**fit** (X, y)

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit_params* and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**get_support** (indices=False)

Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using sklearn.feature_selection.SelectKBest

• Pipeline Anova SVM
• Univariate Feature Selection
• Concatenating multiple feature extraction methods
• Selecting dimensionality reduction with Pipeline and GridSearchCV
• Classification of text documents using sparse features
7.15.4 sklearn.feature_selection.SelectFpr

class sklearn.feature_selection.SelectFpr(**kwargs)
Filter: Select the pvalues below alpha based on a FPR test.

FPR test stands for False Positive Rate test. It controls the total amount of false detections.

Read more in the User Guide.

Parameters

score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See Also”). The default function only works with classification tasks.

alpha [float, default=5e-2] The highest p-value for features to be kept.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.
pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.
f_regression F-value between label/feature for regression tasks.
mutual_info_regression Mutual information for a continuous target.
SelectPercentile Select features based on percentile of the highest scores.
SelectKBest Select features based on the k highest scores.
SelectFdr Select features based on an estimated false discovery rate.
SelectFwe Select features based on family-wise error rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.

Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFpr, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFpr(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 16)
```

### `fit(X, y)`

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

### `fit_transform(X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

### `get_params(deep=True)`

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

### `get_support(indices=False)`

Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.5 sklearn.feature_selection.SelectFdr

class sklearn.feature_selection.SelectFdr(**kwargs)
Filter: Select the p-values for an estimated false discovery rate

This uses the Benjamini-Hochberg procedure. alpha is an upper bound on the expected false discovery rate.

Read more in the User Guide.

Parameters

score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See Also”). The default function only works with classification tasks.

alpha [float, default=5e-2] The highest uncorrected p-value for features to keep.

Attributes
scores_ [array-like of shape (n_features,)] Scores of features.
pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif  ANOVA F-value between label/feature for classification tasks.
mutual_info_classif  Mutual information for a discrete target.
chi2  Chi-squared stats of non-negative features for classification tasks.

**Methods**

- `fit(X, y)`: Run score function on (X, y) and get the appropriate features.
- `fit_transform(X[, y])`: Fit to data, then transform it.
- `get_params([deep])`: Get parameters for this estimator.
- `get_support([indices])`: Get a mask, or integer index, of the features selected.
- `inverse_transform(X)`: Reverse the transformation operation.
- `set_params(**params)`: Set the parameters of this estimator.
- `transform(X)`: Reduce X to the selected features.
The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

`fit_transform` ([X, y=None, **fit_params])

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

`get_params` (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

`get_support` (indices=False)

Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

`inverse_transform` (X)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.
set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

transform (X)

Reduce X to the selected features.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 7.15.6 sklearn.feature_selection.SelectFromModel

**class** sklearn.feature_selection.SelectFromModel(**kwargs)**

Meta-transformer for selecting features based on importance weights.

New in version 0.17.

Read more in the User Guide.

**Parameters**

estimator [object] The base estimator from which the transformer is built. This can be both a fitted (if `prefit` is set to True) or a non-fitted estimator. The estimator must have either a `feature_importances_` or `coef_` attribute after fitting.

threshold [string or float, default=None] The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If “median” (resp. “mean”), then the threshold value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., “1.25*mean”) may also be used. If None and if the estimator has a parameter penalty set to 11, either explicitly or implicitly (e.g, Lasso), the threshold used is 1e-5. Otherwise, “mean” is used by default.

prefit [bool, default=False] Whether a prefit model is expected to be passed into the constructor directly or not. If True, `transform` must be called directly and SelectFromModel cannot be used with `cross_val_score`, `GridSearchCV` and similar utilities that clone the estimator. Otherwise train the model using `fit` and then `transform` to do feature selection.

norm_order [non-zero int, inf, -inf, default=1] Order of the norm used to filter the vectors of coefficients below `threshold` in the case where the `coef_` attribute of the estimator is of dimension 2.

max_features [int, default=None] The maximum number of features to select. To only select based on `max_features`, set `threshold=-np.inf`.

New in version 0.20.
**importance_getter** [str or callable, default='auto'] If ‘auto’, uses the feature importance either through a *coef_* attribute or *feature_importances_* attribute of estimator.

Also accepts a string that specifies an attribute name/path for extracting feature importance (implemented with attrgetter). For example, give *regressor_*._coef_* in case of TransformedTargetRegressor or named_steps.clf.*feature_importances_* in case of Pipeline with its last step named clf.

If callable, overrides the default feature importance getter. The callable is passed with the fitted estimator and it should return importance for each feature.

New in version 0.24.

**Attributes**

- **estimator_** [an estimator] The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the SelectFromModel, i.e when prefit is False.

- **threshold_** [float] The threshold value used for feature selection.

**See also:**

- **RFE** Recursive feature elimination based on importance weights.

- **RFECV** Recursive feature elimination with built-in cross-validated selection of the best number of features.

- **SequentialFeatureSelector** Sequential cross-validation based feature selection. Does not rely on importance weights.

**Notes**

Allows NaN/Inf in the input if the underlying estimator does as well.

**Examples**

```python
>>> from sklearn.feature_selection import SelectFromModel
>>> from sklearn.linear_model import LogisticRegression
>>> X = [[ 0.87, -1.34, 0.31 ],
... [-2.79, -0.02, -0.85 ],
... [-1.34, -0.48, -2.55 ],
... [ 1.92, 1.48, 0.65 ]]
>>> y = [0, 1, 0, 1]
>>> selector = SelectFromModel(LogisticRegression()).fit(X, y)
>>> selector.estimator_.coef_
array([[ 0.3252302 , 0.83462377, 0.49750423]])
>>> selector.threshold_
0.55245...
>>> selector.get_support()
array([False,  True, False])
>>> selector.transform(X)
array([[ 0.87],
[-2.79],
[-1.34],
[ 1.48]])
```

**fit**(X, y=None, **fit_params)

Fit the SelectFromModel meta-transformer.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,), default=None] The target values (integers that correspond to classes in classification, real numbers in regression).

**fit_params** [Other estimator specific parameters]

Returns

- **self** [object]

**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**get_support**(indices=False)

Get a mask, or integer index, of the features selected.

Parameters
**indices**  [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

**support**  [array] An index that selects the retained features from a feature vector. If **indices** is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If **indices** is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**  *(X)*

Reverse the transformation operation

**Parameters**

**X**  [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

**X_r**  [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by **transform**.

**partial_fit**  *(X, y=None, **fit_params)*

Fit the SelectFromModel meta-transformer only once.

**Parameters**

**X**  [array-like of shape (n_samples, n_features)] The training input samples.

**y**  [array-like of shape (n_samples,), default=None] The target values (integers that correspond to classes in classification, real numbers in regression).

**fit_params**  [Other estimator specific parameters]

**Returns**

**self**  [object]

**set_params**  (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as **Pipeline**). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params**  [dict] Estimator parameters.

**Returns**

**self**  [estimator instance] Estimator instance.

**transform**  *(X)*

Reduce X to the selected features.

**Parameters**

**X**  [array of shape [n_samples, n_features]] The input samples.

**Returns**

**X_r**  [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.
Examples using `sklearn.feature_selection.SelectFromModel`  
- *Model-based and sequential feature selection*
- *Classification of text documents using sparse features*

### 7.15.7 `sklearn.feature_selection.SelectFwe`

**class `sklearn.feature_selection.SelectFwe`(**kwargs)  
Filter: Select the p-values corresponding to Family-wise error rate  
Read more in the *User Guide*.

**Parameters**

-score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See Also”). The default function only works with classification tasks.

-alpha [float, default=5e-2] The highest uncorrected p-value for features to keep.

**Attributes**

-scores_ [array-like of shape (n_features,)] Scores of features.

-pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

**See also:**

-f_classif ANOVA F-value between label/feature for classification tasks.

-chi2 Chi-squared stats of non-negative features for classification tasks.

-f_regression F-value between label/feature for regression tasks.

-SelectPercentile Select features based on percentile of the highest scores.

-SelectKBest Select features based on the k highest scores.

-SelectFpr Select features based on a false positive rate test.

-SelectFdr Select features based on an estimated false discovery rate.

-GenericUnivariateSelect Univariate feature selector with configurable mode.

**Examples**

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFwe, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFwe(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 15)
```

</tbody>
</table>

**fit (X, y)**

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**get_support (indices=False)**

Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

**support** [array] An index that selects the retained features from a feature vector. If **indices** is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If **indices** is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(X)
Reverse the transformation operation

**Parameters**

X [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform**(X)
Reduce X to the selected features.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 7.15.8 sklearn.feature_selection.SequentialFeatureSelector

**class** sklearn.feature_selection.SequentialFeatureSelector(**estimator**, *, **n_features_to_select=None, direction='forward', scoring=None, cv=5, n_jobs=None)**

Transformer that performs Sequential Feature Selection.

This Sequential Feature Selector adds (forward selection) or removes (backward selection) features to form a feature subset in a greedy fashion. At each stage, this estimator chooses the best feature to add or remove based on the cross-validation score of an estimator.

Read more in the User Guide.

New in version 0.24.
Parameters

```python
estimator

An unfitted estimator.
```

```python
n_features_to_select

The number of features to select. If `None`, half of the features are selected. If integer, the parameter is the absolute number of features to select. If float between 0 and 1, it is the fraction of features to select.
```

```python
direction: {'forward', 'backward'}, default='forward'

Whether to perform forward selection or backward selection.
```

```python
scoring

A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.
```

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

If None, the estimator’s score method is used.

```python
cv

Determines the cross-validation splitting strategy. Possible inputs for cv are:
```

- `None`, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- `CV splitter`,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

```python
n_jobs

Number of jobs to run in parallel. When evaluating a new feature to add or remove, the cross-validation procedure is parallel over the folds. `None` means 1 unless in a joblib.parallel_backend context. `-1` means using all processors. See Glossary for more details.
```

Attributes

```python
n_features_to_select_

The number of features that were selected.
```

```python
support_

`ndarray of shape (n_features,)`, `dtype=bool` The mask of selected features.
```

See also:

- `RFE` Recursive feature elimination based on importance weights.
- `RFECV` Recursive feature elimination based on importance weights, with automatic selection of the number of features.
- `SelectFromModel` Feature selection based on thresholds of importance weights.
Examples

```python
>>> from sklearn.feature_selection import SequentialFeatureSelector
>>> from sklearn.neighbors import KNeighborsClassifier
>>> from sklearn.datasets import load_iris

>>> X, y = load_iris(return_X_y=True)
>>> knn = KNeighborsClassifier(n_neighbors=3)
>>> sfs = SequentialFeatureSelector(knn, n_features_to_select=3)
>>> sfs.fit(X, y)
SequentialFeatureSelector(estimator=KNeighborsClassifier(n_neighbors=3),
    n_features_to_select=3)
>>> sfs.get_support()
array([ True, False, True, True])
>>> sfs.transform(X).shape
(150, 3)
```

**fit (X, y)**
Learn the features to select.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Training vectors.
- **y** [array-like of shape (n_samples,)] Target values.

**Returns**
- **self** [object]

**fit_transform (X, y=None, **fit_params)**
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Additional fit parameters.**

**Returns**
- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.
get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.
Examples using `sklearn.feature_selection.SequentialFeatureSelector`

- Model-based and sequential feature selection

7.15.9 `sklearn.feature_selection.RFE`

class `sklearn.feature_selection.RFE(**kwargs)`
Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and the importance of each feature is obtained either through any specific attribute or callable. Then, the least important features are pruned from current set of features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the User Guide.

Parameters

- **estimator** [Estimator instance] A supervised learning estimator with a `fit` method that provides information about feature importance (e.g. `coef_`, `feature_importances_`).

- **n_features_to_select** [int or float, default=None] The number of features to select. If None, half of the features are selected. If integer, the parameter is the absolute number of features to select. If float between 0 and 1, it is the fraction of features to select.

  Changed in version 0.24: Added float values for fractions.

- **step** [int or float, default=1] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration.

- **verbose** [int, default=0] Controls verbosity of output.

- **importance_getter** [str or callable, default='auto'] If 'auto', uses the feature importance either through a `coef_` or `feature_importances_` attributes of estimator.

  Also accepts a string that specifies an attribute name/path for extracting feature importance (implemented with `attrgetter`). For example, give `regressor_.coef_` in case of `TargetRegressor` or `named_steps.clf.feature_importances_` in case of class:`~sklearn.pipeline.Pipeline` with its last step named `clf`.

  If callable, overrides the default feature importance getter. The callable is passed with the fitted estimator and it should return importance for each feature.

Attributes

- **estimator_** [Estimator instance] The fitted estimator used to select features.

- **n_features_** [int] The number of selected features.

- **ranking_** [ndarray of shape (n_features,)] The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

- **support_** [ndarray of shape (n_features,)] The mask of selected features.

See also:
**RFECV**  Recursive feature elimination with built-in cross-validated selection of the best number of features.

**SelectFromModel**  Feature selection based on thresholds of importance weights.

**SequentialFeatureSelector**  Sequential cross-validation based feature selection. Does not rely on importance weights.

**Notes**

Allows NaN/Inf in the input if the underlying estimator does as well.

**scikit-learn user guide, Release 0.24.dev0**
Compute the decision function of \( X \).

**Parameters**

- **\( X \)** [[array-like or sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **score** [array, shape = [n_samples, n_classes] or [n_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape [n_samples].

**fit** (\( X, y \))

Fit the RFE model and then the underlying estimator on the selected features.

**Parameters**

- **\( X \)** [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.
- **\( y \)** [array-like of shape (n_samples,)] The target values.

**fit_transform** (\( X, y=None, **fit_params \))

Fit to data, then transform it.

Fits transformer to \( X \) and \( y \) with optional parameters fit_params and returns a transformed version of \( X \).

**Parameters**

- **\( X \)** [array-like of shape (n_samples, n_features)] Input samples.
- **\( y \)** [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**get_support** (indices=False)

Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**
support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

`inverse_transform (X)`
Reverse the transformation operation

**Parameters**

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by `transform`.

`predict (X)`
Reduce X to the selected features and then predict using the underlying estimator.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **y** [array of shape [n_samples]] The predicted target values.

`predict_log_proba (X)`
Predict class log-probabilities for X.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **p** [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

`predict_proba (X)`
Predict class probabilities for X.

**Parameters**

- **X** [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **p** [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

`score (X, y)`
Reduce X to the selected features and then return the score of the underlying estimator.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.
- **y** [array of shape [n_samples]] The target values.
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform**(X)  
Reduce X to the selected features.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.RFE`

- Recursive feature elimination

**7.15.10 sklearn.feature_selection.RFECV**

class `sklearn.feature_selection.RFECV` (**kwargs**)  
Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

See glossary entry for `cross-validation estimator`.

Read more in the `User Guide`.

**Parameters**

**estimator** [Estimator instance] A supervised learning estimator with a `fit` method that provides information about feature importance either through a `coef_` attribute or through a `feature_importances_` attribute.

**step** [int or float, default=1] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration. Note that the last iteration may remove fewer than `step` features in order to reach `min_features_to_select`.

**min_features_to_select** [int, default=1] The minimum number of features to be selected. This number of features will always be scored, even if the difference between the original feature count and `min_features_to_select` isn’t divisible by `step`.

New in version 0.20.

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 5-fold cross-validation,
• integer, to specify the number of folds.

• **CV splitter**, an iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if \( y \) is binary or multiclass, **StratifiedKFold** is used. If the estimator is a classifier or if \( y \) is neither binary nor multiclass, **KFold** is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: \( cv \) default value of None changed from 3-fold to 5-fold.

**scoring** [string, callable or None, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**verbose** [int, default=0] Controls verbosity of output.

**n_jobs** [int or None, default=None] Number of cores to run in parallel while fitting across folds. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

New in version 0.18.

**importance_getter** [str or callable, default=’auto’] If ‘auto’, uses the feature importance either through a `coef_` or `feature_importances_` attributes of estimator.

Also accepts a string that specifies an attribute name/path for extracting feature importance. For example, give `regressor_.coef_` in case of `TransformedTargetRegressor` or `named_steps.clf.feature_importances_` in case of `Pipeline` with its last step named `clf`.

If callable, overrides the default feature importance getter. The callable is passed with the fitted estimator and it should return importance for each feature.

New in version 0.24.

**Attributes**

**estimator_** [Estimator instance] The fitted estimator used to select features.

**grid_scores_** [ndarray of shape (n_subsets_of_features,)] The cross-validation scores such that `grid_scores_[i]` corresponds to the CV score of the i-th subset of features.

**n_features_** [int] The number of selected features with cross-validation.

**ranking_** [array of shape (n_features,)] The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

**support_** [ndarray of shape (n_features,)] The mask of selected features.

See also:

**RFE** Recursive feature elimination.
Notes

The size of grid_scores_ is equal to \( \text{ceil} \left( \frac{n\_features - \text{min}\_features\_to\_select}{\text{step}} \right) + 1 \), where step is the number of features removed at each iteration.

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFECV
>>> from sklearn.svm import SVR

>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFECV(estimator, step=1, cv=5)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True, True, True, True, True, False, False, False, False, False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

Methods

decision_function(X)  
Compute the decision function of X.

fit(X, y[, groups])  
Fit the RFE model and automatically tune the number of selected

fit_transform(X[, y])  
Fit to data, then transform it.

get_params([deep])  
Get parameters for this estimator.

get_support([indices])  
Get a mask, or integer index, of the features selected

inverse_transform(X)  
Reverse the transformation operation

predict(X)  
Reduce X to the selected features and then predict using the

predict_log_proba(X)  
Predict class log-probabilities for X.

predict_probas(X)  
Predict class probabilities for X.

score(X, y)  
Reduce X to the selected features and then return the score of the

set_params(**params)  
Set the parameters of this estimator.

transform(X)  
Reduce X to the selected features.

decision_function(X)  
Compute the decision function of X.

Parameters
X \text{ [[array-like or sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.}

Returns

score \text{ [array, shape = \{n_samples, n_classes\] or \{n_samples\] The decision function of the input samples. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape \{n_samples\].}

fit (X, y, groups=None)

Fit the RFE model and automatically tune the number of selected features.

Parameters

X \text{ [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the total number of features.}

y \text{ [array-like of shape (n_samples,)] Target values (integers for classification, real numbers for regression).}

groups \text{ [array-like of shape (n_samples,)] or None, default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold). New in version 0.20.}

fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X \text{ [array-like of shape (n_samples, n_features)] Input samples.}

y \text{ [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).}

**fit_params \text{ [dict] Additional fit parameters.}

Returns

X_new \text{ [ndarray array of shape (n_samples, n_features_new)] Transformed array.}

get_params (deep=True)

Get parameters for this estimator.

Parameters

depth \text{ [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.}

Returns

params \text{ [dict] Parameter names mapped to their values.}

get_support (indices=False)

Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(X)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

predict(X)

Reduce X to the selected features and then predict using the underlying estimator.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

y [array of shape [n_samples]] The predicted target values.

predict_log_proba(X)

Predict class log-probabilities for X.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

p [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba(X)

Predict class probabilities for X.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score(X, y)

Reduce X to the selected features and then return the score of the underlying estimator.
Parameters

- **X** [array of shape [n_samples, n_features]] The input samples.
- **y** [array of shape [n_samples]] The target values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** (**X**)

Reduce X to the selected features.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

**Examples using sklearn.feature_selection.RFECV**

- Recursive feature elimination with cross-validation

7.15.11 sklearn.feature_selection.VarianceThreshold

class sklearn.feature_selection.VarianceThreshold(**threshold=0.0**)

Feature selector that removes all low-variance features.

This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used for unsupervised learning.

Read more in the User Guide.

**Parameters**

- **threshold** [float, default=0] Features with a training-set variance lower than this threshold will be removed. The default is to keep all features with non-zero variance, i.e. remove the features that have the same value in all samples.

**Attributes**

- **variances_** [array, shape (n_features,)] Variances of individual features.
Notes

 Allows NaN in the input. Raises ValueError if no feature in X meets the variance threshold.

Examples

The following dataset has integer features, two of which are the same in every sample. These are removed with the default setting for threshold:

```python
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

**fit**(X, y=None)

Learn empirical variances from X.

**Parameters**

- **X** [array-like, sparse matrix], shape (n_samples, n_features) Sample vectors from which to compute variances.
- **y** [any, default=None] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

**Returns**

- **self**

**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params [dict] Additional fit parameters.

**Returns**

- **X** [array-like of shape (n_samples, n_features)] Transformed input.
- **y** [array-like of shape (n_samples, n_outputs), default=None] Transformed target.
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than
a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If
indices is False, this is a boolean array of shape [# input features], in which an ele-
ment is True iff its corresponding feature is selected for retention. If indices is True,
this is an integer array of shape [# output features] whose values are indices into the input
feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted
where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns
The input samples with only the selected features.

- **feature_selection.chi2**
  - **Parameters**
    - X [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample vectors.
    - y [array-like of shape (n_samples,)] Target vector (class labels).
  - **Returns**
    - chi2 [array, shape = (n_features,)] chi2 statistics of each feature.
    - pval [array, shape = (n_features,)] p-values of each feature.
  - **See also**
    - **f_classif** ANOVA F-value between label/feature for classification tasks.
    - **f_regression** F-value between label/feature for regression tasks.
  - **Notes**
    - Complexity of this algorithm is O(n_classes * n_features).
Examples using `sklearn.feature_selection.chi2`

- Selecting dimensionality reduction with Pipeline and GridSearchCV
- SVM-Anova: SVM with univariate feature selection
- Classification of text documents using sparse features

7.15.13 `sklearn.feature_selection.f_classif`

```python
sklearn.feature_selection.f_classif(X, y)
```

Compute the ANOVA F-value for the provided sample.

See also:
- `chi2` Chi-squared stats of non-negative features for classification tasks.
- `f_regression` F-value between label/feature for regression tasks.

Examples using `sklearn.feature_selection.f_classif`

- Pipeline Anova SVM
- Univariate Feature Selection

7.15.14 `sklearn.feature_selection.f_regression`

```python
sklearn.feature_selection.f_regression(X, y, *, center=True)
```

Univariate linear regression tests.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is, \(((X[:, i] - \text{mean}(X[:, i])) \times (y - \text{mean}_y)) / (\text{std}(X[:, i]) \times \text{std}(y))\).
2. It is converted to an F score then to a p-value.

For more on usage see the User Guide.

Parameters

- `X` [array-like, sparse matrix] shape = (n_samples, n_features) The set of regressors that will be tested sequentially.

7.15. `sklearn.feature_selection: Feature Selection`
**y** [array of shape(n_samples,)] The data matrix

**center** [bool, default=True] If true, X and y will be centered.

**Returns**

**F** [array, shape=(n_features,)] F values of features.

**pval** [array, shape=(n_features,)] p-values of F-scores.

**See also:**

- :func:`mutual_info_regression` Mutual information for a continuous target.
- :func:`f_classif` ANOVA F-value between label/feature for classification tasks.
- :func:`chi2` Chi-squared stats of non-negative features for classification tasks.
- :func:`SelectKBest` Select features based on the k highest scores.
- :func:`SelectFpr` Select features based on a false positive rate test.
- :func:`SelectFdr` Select features based on an estimated false discovery rate.
- :func:`SelectFwe` Select features based on family-wise error rate.
- :func:`SelectPercentile` Select features based on percentile of the highest scores.

**Examples using sklearn.feature_selection.f_regression**

- Feature agglomeration vs. univariate selection
- Comparison of F-test and mutual information

7.15.15 sklearn.feature_selection.mutual_info_classif

.. autofunction:: sklearn.feature_selection.mutual_info_classif(X, y, *, discrete_features='auto', n_neighbors=3, copy=True, random_state=None)

Estimate mutual information for a discrete target variable.

Mutual information (MI) \[1\] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the User Guide.

**Parameters**

**X** [array-like or sparse matrix, shape (n_samples, n_features)] Feature matrix.

**y** [array-like of shape (n_samples,)] Target vector.

**discrete_features** [{'auto', bool, array-like}, default='auto'] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense X and to True for sparse X.
n_neighbors [int, default=3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.

copy [bool, default=True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

random_state [int, RandomState instance or None, default=None] Determines random number generation for adding small noise to continuous variables in order to remove repeated values. Pass an int for reproducible results across multiple function calls. See Glossary.

Returns

mi [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

Notes

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

References

7.16 sklearn.gaussian_process: Gaussian Processes

The sklearn.gaussian_process module implements Gaussian Process based regression and classification.

User guide: See the Gaussian Processes section for further details.

gaussian_process.
GaussianProcessClassifier(...) Gaussian process classification (GPC) based on Laplace approximation.
gaussian_process.
GaussianProcessRegressor(...) Gaussian process regression (GPR).

7.16.1 sklearn.gaussian_process.GaussianProcessClassifier

class sklearn.gaussian_process.GaussianProcessClassifier(**kwars)
Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.

Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus rest classifiers are fitted. Note that this class thus does not implement a true multi-
class Laplace approximation.

Read more in the User Guide.

Parameters

kernel [kernel instance, default=None] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 * RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

optimizer ['fmin_l_bfgs_b' or callable, default='fmin_l_bfgs_b'] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```python
def optimizer(obj_func, initial_theta, bounds):
    # 'obj_func' is the objective function to be maximized, which
takes the hyperparameters theta as parameter and an
# optional flag eval_gradient, which determines if the
# gradient is returned additionally to the function value
# 'initial_theta': the initial value for theta, which can be
# used by local optimizers
# 'bounds': the bounds on the values of theta
#
    # Returned are the best found hyperparameters theta and
# the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the ‘L-BFGS-B’ algorithm from scipy.optimize.minimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

- `'fmin_l_bfgs_b'`

n_restarts_optimizer [int, default=0] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer=0 implies that one run is performed.

max_iter_predict [int, default=100] The maximum number of iterations in Newton’s method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

warm_start [bool, default=False] If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of _posterior_mode(). This can speed up convergence when _posterior_mode is called several times on similar problems as in hyperparameter optimization. See the Glossary.

copy_X_train [bool, default=True] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

random_state [int, RandomState instance or None, default=None] Determines random number generation used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

multi_class ["one_vs_rest", "one_vs_one", default="one_vs_rest"] Specifies how multi-class classification problems are handled. Supported are ‘one_vs_rest’ and ‘one_vs_one’. In
‘one_vs_rest’, one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In ‘one_vs_one’, one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that ‘one_vs_one’ does not support predicting probability estimates.

n_jobs [int, default=None] The number of jobs to use for the computation: the specified multiclass problems are computed in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

base_estimator_ [Estimator instance] The estimator instance that defines the likelihood function using the observed data.

kernel_ [kernel instance] The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

log_marginal_likelihood_value_ [float] The log-marginal-likelihood of self.kernel_.theta

classes_ [array-like of shape (n_classes,)] Unique class labels.

n_classes_ [int] The number of classes in the training data

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import RBF

>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * RBF(1.0)
>>> gpc = GaussianProcessClassifier(kernel=kernel,
...                               random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2,:])
array([[0.83548752, 0.03228706, 0.13222543],
       [0.79064206, 0.06525643, 0.14410151]])
```

New in version 0.18.

Methods

```python
fit(X, y) Fit Gaussian process classification model
get_params([deep]) Get parameters for this estimator.
log_marginal_likelihood([theta, ...]) Returns log-marginal likelihood of theta for training data.
predict(X) Perform classification on an array of test vectors X.
predict_proba(X) Return probability estimates for the test vector X.
score(X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.
```
Table 124 – continued from previous page

| **set_params(**params)** | Set the parameters of this estimator. |

**fit** *(X, y)*

Fit Gaussian process classification model

**Parameters**

- **X** [array-like of shape (n_samples, n_features) or list of object] Feature vectors or other representations of training data.
- **y** [array-like of shape (n_samples,)] Target values, must be binary

**Returns**

- **self** [returns an instance of self.]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**log_marginal_likelihood** *(theta=None, eval_gradient=False, clone_kernel=True)*

Returns log-marginal likelihood of theta for training data.

In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers are returned.

**Parameters**

- **theta** [array-like of shape (n_kernel_params,), default=None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification, theta may be the hyperparameters of the compound kernel or of an individual kernel. In the latter case, all individual kernel get assigned the same theta values. If None, the precomputed log_marginal_likelihood of self.kernel_.theta is returned.
- **eval_gradient** [bool, default=False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that gradient computation is not supported for non-binary classification. If True, theta must not be None.
- **clone_kernel** [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

**Returns**

- **log_likelihood** [float] Log-marginal likelihood of theta for training data.
- **log_likelihood_gradient** [ndarray of shape (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

**predict** *(X)*

Perform classification on an array of test vectors X.

**Parameters**
X [array-like of shape (n_samples, n_features) or list of object] Query points where the GP is evaluated for classification.

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X, values are from classes_

predict_proba (X)
Return probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features) or list of object] Query points where the GP is evaluated for classification.

Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.gaussian_process.GaussianProcessClassifier`

- Plot classification probability
- Classifier comparison
- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Gaussian process classification (GPC) on iris dataset
- Iso-probability lines for Gaussian Processes classification (GPC)
- Probabilistic predictions with Gaussian process classification (GPC)
- Gaussian processes on discrete data structures

7.16.2 `sklearn.gaussian_process.GaussianProcessRegressor`

class `sklearn.gaussian_process.GaussianProcessRegressor(**kwargs)`

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, GaussianProcessRegressor:

- allows prediction without prior fitting (based on the GP prior)
- provides an additional method `sample_y(X)`, which evaluates samples drawn from the GPR (prior or posterior) at given inputs
- exposes a method `log_marginal_likelihood(theta)`, which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the User Guide.

New in version 0.18.

Parameters

- `kernel` [kernel instance, default=None] The kernel specifying the co-variance function of the GP. If None is passed, the kernel `ConstantKernel(1.0, constant_value_bounds="fixed" * RBF(1.0, length_scale_bounds="fixed")` is used as default. Note that the kernel hyperparameters are optimized during fitting unless the bounds are marked as “fixed”.

- `alpha` [float or ndarray of shape (n_samples,), default=1e-10] Value added to the diagonal of the kernel matrix during fitting. This can prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite matrix. It can also be interpreted as the variance of additional Gaussian measurement noise on the training observations. Note that this is different from using a `WhiteKernel`. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

- `optimizer` [“fmin_l_bfgs_b” or callable, default=”fmin_l_bfgs_b”] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```python
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be minimized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the ‘L-BFGS-B’ algorithm from scipy.optimize.minimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

**n_restarts_optimizer** [int, default=0] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer == 0 implies that one run is performed.

**normalize_y** [bool, default=False] Whether the target values y are normalized, the mean and variance of the target values are set equal to 0 and 1 respectively. This is recommended for cases where zero-mean, unit-variance priors are used. Note that, in this implementation, the normalisation is reversed before the GP predictions are reported.

Changed in version 0.23.

**copy_X_train** [bool, default=True] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

**Attributes**

- **X_train_** [array-like of shape (n_samples, n_features) or list of object] Feature vectors or other representations of training data (also required for prediction).
- **y_train_** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values in training data (also required for prediction)
- **kernel_** [kernel instance] The kernel used for prediction. The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters
- **L_** [array-like of shape (n_samples, n_samples)] Lower-triangular Cholesky decomposition of the kernel in X_train_
- **alpha_** [array-like of shape (n_samples,)] Dual coefficients of training data points in kernel space
- **log_marginal_likelihood_value_** [float] The log-marginal-likelihood of self.kernel_

theta
Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)

>>> kernel = DotProduct() + WhiteKernel()

>>> gpr = GaussianProcessRegressor(kernel=kernel, random_state=0).fit(X, y)

>>> gpr.score(X, y)
0.3680...

>>> gpr.predict(X[:2, :], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

</table>

**fit** ($X, y$)

Fit Gaussian process regression model.

**Parameters**

- **$X$** [array-like of shape (n_samples, n_features) or list of object] Feature vectors or other representations of training data.
- **$y$** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values

**Returns**

- **self** [returns an instance of self.]

**get_params**(deep=**True**)  
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**log_marginal_likelihood**(theta=None, eval_gradient=False, clone_kernel=True)

Returns log-marginal likelihood of theta for training data.

**Parameters**

- **theta** [list of length n_kernel] Hyperparameters of the kernel.
- **eval_gradient** [bool, default=False] Whether to also return the gradient with respect to theta.
- **clone_kernel** [bool, default=True] Whether to make a deep copy of the kernel or not.

7.16. **sklearn.gaussian_process**: Gaussian Processes
theta [array-like of shape (n_kernel_params,) default=None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed log_marginal_likelihood of self.kernel_.theta is returned.

eval_gradient [bool, default=False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

clon_kernel [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

Returns

log_likelihood [float] Log-marginal likelihood of theta for training data.

log_likelihood_gradient [ndarray of shape (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

predict (X, return_std=False, return_cov=False)
Predict using the Gaussian process regression model

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (return_std=True) or covariance (return_cov=True). Note that at most one of the two can be requested.

Parameters

X [array-like of shape (n_samples, n_features) or list of object] Query points where the GP is evaluated.

return_std [bool, default=False] If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.

return_cov [bool, default=False] If True, the covariance of the joint predictive distribution at the query points is returned along with the mean.

Returns

y_mean [ndarray of shape (n_samples, [n_output_dims])] Mean of predictive distribution at query points.

y_std [ndarray of shape (n_samples,), optional] Standard deviation of predictive distribution at query points. Only returned when return_std is True.

y_cov [ndarray of shape (n_samples, n_samples), optional] Covariance of joint predictive distribution at query points. Only returned when return_cov is True.

sample_y (X, n_samples=1, random_state=0)
Draw samples from Gaussian process and evaluate at X.

Parameters

X [array-like of shape (n_samples, n_features) or list of object] Query points where the GP is evaluated.

n_samples [int, default=1] The number of samples drawn from the Gaussian process

random_state [int, RandomState instance or None, default=0] Determines random number generation to randomly draw samples. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

Returns
**y_samples** [ndarray of shape (n_samples, [n_output_dims], n_samples)] Values of n_samples samples drawn from Gaussian process and evaluated at query points.

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of $r2_score$. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.gaussian_process.GaussianProcessRegressor**

- Comparison of kernel ridge and Gaussian process regression
- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian Processes regression: basic introductory example
- Gaussian process regression (GPR) on Mauna Loa CO2 data.
- Gaussian processes on discrete data structures
### gaussian_process.kernels.CompoundKernel

**class sklearn.gaussian_process.kernels.CompoundKernel(kernels)**

Kernel which is composed of a set of other kernels.

New in version 0.18.

**Parameters**

- kernels [list of Kernels] The other kernels

**Attributes**

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on discrete structures.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.
Examples

```python
>>> from sklearn.gaussian_process.kernels import WhiteKernel
>>> from sklearn.gaussian_process.kernels import RBF
>>> from sklearn.gaussian_process.kernels import CompoundKernel

>>> kernel = CompoundKernel([
...     WhiteKernel(noise_level=3.0),
...     RBF(length_scale=2.0)])

>>> print(kernel.bounds)
[[-11.51292546  11.51292546]
 [-11.51292546  11.51292546]]

>>> print(kernel.n_dims)
2

>>> print(kernel.theta)
[1.09861229  0.69314718]
```

Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object, default=None] Left argument of the returned kernel k(X, Y)
Y [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.
eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y, n_kernels)] Kernel k(X, Y)
K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims, n_kernels), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta
```
**clone_with_theta**(theta)

Returns a clone of self with given hyperparameters theta.

**Parameters**

theta [ndarray of shape (n_dims,)] The hyperparameters

**diag**(X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

**Returns**

K_diag [ndarray of shape (n_samples_X, n_kernels)] Diagonal of kernel k(X, X)

**get_params**(deep=True)

Get parameters of this kernel.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter specifications.

**is_stationary**()

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Returns whether the kernel is defined on discrete structures.

**set_params**(**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a sum-kernel, where it modifies the mean of the Gaussian process.

\[
k(x_1, x_2) = \text{constant\_value} \quad \forall \ x_1, x_2
\]

Adding a constant kernel is equivalent to adding a constant:

```python
ekernel = RBF() + ConstantKernel(constant_value=2)
```

is the same as:

```python
ekernel = RBF() + 2
```

Read more in the User Guide.

New in version 0.18.

Parameters

- **constant_value** [float, default=1.0] The constant value which defines the covariance: \( k(x_1, x_2) = \text{constant\_value} \)
- **constant_value_bounds** [pair of floats >= 0 or “fixed”, default=(1e-05, 1e5)] The lower and upper bound on \( \text{constant\_value} \). If set to “fixed”, \( \text{constant\_value} \) cannot be changed during hyperparameter tuning.

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameter_constant_value**
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Whether the kernel works only on fixed-length feature vectors.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import RBF, ConstantKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)

>>> kernel = RBF() + ConstantKernel(constant_value=2)

>>> gpr = GaussianProcessRegressor(kernel=kernel, alpha=5, random_state=0).fit(X, y)

>>> gpr.score(X, y)
0.3696...

>>> gpr.predict(X[[1, :]], return_std=True)
(array([606.1...]), array([0.24...]))
```
Methods

__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.

__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel k(X, Y)

Y [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the kernel hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

call_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

glp_params (deep=True)
Get parameters of this kernel.
Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter specifications.

**is_stationary()**

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Whether the kernel works only on fixed-length feature vectors.

**set_params(**params**)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

**self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

Returns

**theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the
kernel

Examples using sklearn.gaussian_process.kernels.ConstantKernel

- Illustration of prior and posterior Gaussian process for different kernels
- Iso-probability lines for Gaussian Processes classification (GPC)
- Gaussian Processes regression: basic introductory example

7.16.5 sklearn.gaussian_process.kernels.DotProduct

**class** sklearn.gaussian_process.kernels.DotProduct

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting $N(0, 1)$ priors on
the coefficients of $x_d(d = 1, ..., D)$ and a prior of $N(0, \sigma_0^2)$ on the bias. The DotProduct kernel is invariant to
a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter $\sigma_0 \sigma$
which controls the inhomogeneity of the kernel. For $\sigma_0^2 = 0$, the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

$$k(x_i, x_j) = \sigma_0^2 + x_i \cdot x_j$$

The DotProduct kernel is commonly combined with exponentiation.

See [1], Chapter 4, Section 4.2, for further details regarding the DotProduct kernel.

Read more in the User Guide.

New in version 0.18.

Parameters

- **sigma_0** [float >= 0, default=1.0] Parameter controlling the inhomogeneity of the kernel. If sigma_0=0, the kernel is homogenous.

- **sigma_0_bounds** [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘sigma_0’. If set to “fixed”, ‘sigma_0’ cannot be changed during hyperparameter tuning.

Attributes

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_sigma_0**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.

- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel
>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel()
>>> gpr = GaussianProcessRegressor(kernel=kernel,
... random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:2, :], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```
### Methods

- **__call__(X[, Y, eval_gradient])**
  Return the kernel $k(X, Y)$ and optionally its gradient.

- **clone_with_theta(theta)**
  Returns a clone of self with given hyperparameters theta.

- **diag(X)**
  Returns the diagonal of the kernel $k(X, X)$.

- **get_params([deep])**
  Get parameters of this kernel.

- **is_stationary()**
  Returns whether the kernel is stationary.

- **set_params(**params)**
  Set the parameters of this kernel.

---

**__call__(X, Y=None, eval_gradient=False)**

Return the kernel $k(X, Y)$ and optionally its gradient.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel $k(X, Y)$.
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel $k(X, Y)$. If None, $k(X, X)$ if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

**Returns**

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel $k(X, Y)$.
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel $k(X, X)$ with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- **bounds** [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta.

- **clone_with_theta(theta)**
  Returns a clone of self with given hyperparameters theta.

**Parameters**

- **theta** [ndarray of shape (n_dims,)] The hyperparameters.

- **diag(X)**
  Returns the diagonal of the kernel $k(X, X)$.

  The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel $k(X, Y)$.

**Returns**

- **K_diag** [ndarray of shape (n_samples_X,)] Diagonal of kernel $k(X, X)$.
get_params (deep=True)
Get parameters of this kernel.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel.

Examples using sklearn.gaussian_process.kernels.DotProduct

- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Illustration of prior and posterior Gaussian process for different kernels
- Iso-probability lines for Gaussian Processes classification (GPC)
7.16.6 sklearn.gaussian_process.kernels.ExpSineSquared

class sklearn.gaussian_process.kernels.ExpSineSquared(length_scale=1.0, periodicity=1.0, length_scale_bounds=(1e-05, 100000.0), periodicity_bounds=(1e-05, 100000.0))

Exp-Sine-Squared kernel (aka periodic kernel).

The ExpSineSquared kernel allows one to model functions which repeat themselves exactly. It is parameterized by a length scale parameter \( l > 0 \) and a periodicity parameter \( p > 0 \). Only the isotropic variant where \( l \) is a scalar is supported at the moment. The kernel is given by:

\[
k(x_i, x_j) = \exp\left(-\frac{2 \sin^2(\pi d(x_i, x_j)/p)}{l^2}\right)
\]

where \( l \) is the length scale of the kernel, \( p \) the periodicity of the kernel and \( d(cdot, cdot) \) is the Euclidean distance.

Read more in the User Guide.

New in version 0.18.

Parameters

- **length_scale** [float > 0, default=1.0] The length scale of the kernel.
- **periodicity** [float > 0, default=1.0] The periodicity of the kernel.
- **length_scale_bounds** [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyper-parameter tuning.
- **periodicity_bounds** [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘periodicity’. If set to “fixed”, ‘periodicity’ cannot be changed during hyperparameter tuning.

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameter_length_scale** Returns the length scale
- **hyperparameter_periodicity**
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.
Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import ExpSineSquared

>>> X, y = make_friedman2(n_samples=50, noise=0, random_state=0)
>>> kernel = ExpSineSquared(length_scale=1, periodicity=1)
>>> gpr = GaussianProcessRegressor(kernel=kernel, alpha=5,
...                               random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.0144...
>>> gpr.predict(X[:2, :], return_std=True)
(array([425.6..., 457.5...]), array([0.3894..., 0.3467...]))
```
theta [ndarray of shape (n_dims,)] The hyperparameters

diag (X)
Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns
K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters
dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

property hyperparameter_length_scale
Returns the length scale

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns
theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
Examples using `sklearn.gaussian_process.kernels.ExpSineSquared`

- Comparison of kernel ridge and Gaussian process regression
- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.16.7 `sklearn.gaussian_process.kernels.Exponentiation`

class `sklearn.gaussian_process.kernels.Exponentiation(kernel, exponent)`

The Exponentiation kernel takes one base kernel and a scalar parameter $p$ and combines them via

$$ k_{exp}(X, Y) = k(X, Y)^p $$

Note that the `__pow__` magic method is overridden, so `Exponentiation(RBF(), 2)` is equivalent to using the `**` operator with `RBF() ** 2`.

Read more in the User Guide.

New in version 0.18.

Parameters

- `kernel` [Kernel] The base kernel
- `exponent` [float] The exponent for the base kernel

Attributes

- `bounds` Returns the log-transformed bounds on the theta.
- `hyperparameters` Returns a list of all hyperparameters.
- `n_dims` Returns the number of non-fixed hyperparameters of the kernel.
- `requires_vector_input` Returns whether the kernel is defined on discrete structures.
- `theta` Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import (RationalQuadratic,
...                                               Exponentiation)

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)

>>> kernel = Exponentiation(RationalQuadratic(), exponent=2)

>>> gpr = GaussianProcessRegressor(kernel=kernel, alpha=5,
...                                 random_state=0).fit(X, y)

>>> gpr.score(X, y)
0.419...

>>> gpr.predict(X[:,1:], return_std=True)
(array([635.5...]), array([0.559...]))
```
Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

```python
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the
returned kernel k(X, Y)

Y [array-like of shape (n_samples_Y, n_features) or list of object, default=None] Right
argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log
of the kernel hyperparameter is computed.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradi-
ent of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only
returned when eval_gradient is True.
```

```python
property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyper-
parameters theta

close_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently
since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)
```

```python
get_params (deep=True)
Get parameters of this kernel.
```
Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter.

**is_stationary()**

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Returns whether the kernel is defined on discrete structures.

**set_params(**params**)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form 
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

**self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

**theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 7.16.8 sklearn.gaussian_process.kernels.Hyperparameter

**class sklearn.gaussian_process.kernels.Hyperparameter(name, value_type, bounds, n_elements=1, fixed=None)**

A kernel hyperparameter’s specification in form of a namedtuple.

New in version 0.18.

**Attributes**

**name** [str] The name of the hyperparameter. Note that a kernel using a hyperparameter with name “x” must have the attributes self.x and self.x_bounds

**value_type** [str] The type of the hyperparameter. Currently, only “numeric” hyperparameters are supported.

**bounds** [pair of floats >= 0 or “fixed”] The lower and upper bound on the parameter. If n_elements>1, a pair of 1d array with n_elements each may be given alternatively. If the string “fixed” is passed as bounds, the hyperparameter’s value cannot be changed.
**n_elements** [int, default=1] The number of elements of the hyperparameter value. Defaults to 1, which corresponds to a scalar hyperparameter. n_elements > 1 corresponds to a hyperparameter which is vector-valued, such as, e.g., anisotropic length-scales.

**fixed** [bool, default=None] Whether the value of this hyperparameter is fixed, i.e., cannot be changed during hyperparameter tuning. If None is passed, the “fixed” is derived based on the given bounds.

### Examples

```python
>>> from sklearn.gaussian_process.kernels import ConstantKernel
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import Hyperparameter

>>> X, y = make_friedman2(n_samples=50, noise=0, random_state=0)
>>> kernel = ConstantKernel(constant_value=1.0,
...                          constant_value_bounds=(0.0, 10.0))

We can access each hyperparameter:

```python
>>> for hyperparameter in kernel.hyperparameters:
...     print(hyperparameter)
Hyperparameter(name='constant_value', value_type='numeric', bounds=[[ 0., 10.]], n_elements=1, fixed=False)
```

```python
>>> params = kernel.get_params()
>>> for key in sorted(params): print(f"{key}: {params[key]}")
constant_value : 1.0
constant_value_bounds : (0.0, 10.0)
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>count(value, /)</code></td>
<td>Return number of occurrences of value.</td>
</tr>
<tr>
<td><code>index(value[, start, stop])</code></td>
<td>Return first index of value.</td>
</tr>
<tr>
<td><code>__call__(*args, **kwargs)</code></td>
<td>Call self as a function.</td>
</tr>
</tbody>
</table>

**counts**

Alias for field number 2

**count** (value, /)

Return number of occurrences of value.

**fixed**

Alias for field number 4

**index**(value, start=0, stop=sys.maxsize, /)

Return first index of value.

Raises ValueError if the value is not present.

**n_elements**

Alias for field number 3
Examples using `sklearn.gaussian_process.kernels.Hyperparameter`

- Gaussian processes on discrete data structures

### 7.16.9 `sklearn.gaussian_process.kernels.Kernel`

**class** `sklearn.gaussian_process.kernels.Kernel`

Base class for all kernels.

New in version 0.18.

**Attributes**

- `bounds` Returns the log-transformed bounds on the theta.
- `hyperparameters` Returns a list of all hyperparameter specifications.
- `n_dims` Returns the number of non-fixed hyperparameters of the kernel.
- `requires_vector_input` Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- `theta` Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__call__</code>(X, Y=None, eval_gradient=False)</td>
<td>Evaluate the kernel.</td>
</tr>
<tr>
<td><code>clone_with_theta</code>(theta)</td>
<td>Returns a clone of self with given hyperparameters theta.</td>

<tr>
<td><code>is_stationary</code>()</td>
<td>Returns whether the kernel is stationary.</td>
</tr>
<tr>
<td><code>set_params</code>(**params)</td>
<td>Set the parameters of this kernel.</td>
</tr>
</tbody>
</table>

**abstract** `__call__`(X, Y=None, eval_gradient=False)

Evaluate the kernel.

**property** `bounds`

Returns the log-transformed bounds on the theta.

**Returns**

- `bounds` [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**`clone_with_theta`(theta)***

Returns a clone of self with given hyperparameters theta.

**Parameters**

- `theta` [ndarray of shape (n_dims,)] The hyperparameters
abstract diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently
since only the diagonal is evaluated.

Parameters
X [array-like of shape (n_samples,)] Left argument of the returned kernel k(X, Y)

Returns
K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

abstract is_stationary()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True
for backward compatibility.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

Returns
theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the
kernel
Examples using sklearn.gaussian_process.kernels.Kernel

- Gaussian processes on discrete data structures

7.16.10 sklearn.gaussian_process.kernels.Matern

```python
class sklearn.gaussian_process.kernels.Matern(length_scale=1.0, length_scale_bounds=(1e-05, 100000.0), nu=1.5)
```

Matern kernel.

The class of Matern kernels is a generalization of the RBF. It has an additional parameter \( \nu \) which controls the smoothness of the resulting function. The smaller \( \nu \), the less smooth the approximated function is. As \( \nu \to \infty \), the kernel becomes equivalent to the RBF kernel. When \( \nu = 1/2 \), the Matérn kernel becomes identical to the absolute exponential kernel. Important intermediate values are \( \nu = 1.5 \) (once differentiable functions) and \( \nu = 2.5 \) (twice differentiable functions).

The kernel is given by:

\[
k(x_i, x_j) = \frac{1}{\Gamma(\nu)2^{\nu-1}} (\frac{\sqrt{2\nu}}{l} d(x_i, x_j))^{\nu} K_\nu \left( \frac{\sqrt{2\nu}}{l} d(x_i, x_j) \right)
\]

where \( d(\cdot, \cdot) \) is the Euclidean distance, \( K_\nu(\cdot) \) is a modified Bessel function and \( \Gamma(\cdot) \) is the gamma function. See [1], Chapter 4, Section 4.2, for details regarding the different variants of the Matern kernel.

Read more in the User Guide.

New in version 0.18.

Parameters

- **length_scale** [float or ndarray of shape (n_features,), default=1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of \( l \) defines the length-scale of the respective feature dimension.

- **length_scale_bounds** [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.

- **nu** [float, default=1.5] The parameter \( \nu \) controlling the smoothness of the learned function. The smaller \( \nu \), the less smooth the approximated function is. For \( \nu = \infty \), the kernel becomes equivalent to the RBF kernel and for \( \nu = 0.5 \) to the absolute exponential kernel. Important intermediate values are \( \nu = 1.5 \) (once differentiable functions) and \( \nu = 2.5 \) (twice differentiable functions). Note that values of \( \nu \) not in \([0.5, 1.5, 2.5, \infty]\) incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to \( l \), \( \nu \) is kept fixed to its initial value and not optimized.

Attributes

- **anisotropic**

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_length_scale**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import Matern

>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * Matern(length_scale=1.0, nu=1.5)
>>> gpc = GaussianProcessClassifier(kernel=kernel, ... random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2, :])
array([[0.8513..., 0.0368..., 0.1117...],
       [0.8086..., 0.0693..., 0.1220...]])
```

Methods

```python
def __call__(X[, Y, eval_gradient])
    Return the kernel k(X, Y) and optionally its gradient.

cdef clone_with_theta(\theta)
    Returns a clone of self with given hyperparameters \theta.

def diag(X)
    Returns the diagonal of the kernel k(X, X).

def get_params([deep])
    Get parameters of this kernel.

def is_stationary()
    Returns whether the kernel is stationary.

def set_params(**params)
    Set the parameters of this kernel.
```

__call__ (X, Y=None, eval_gradient=False)
  Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.
property bounds

Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

close_with_theta (theta)

Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters

diag (X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

generate_params (deep=True)

Get parameters of this kernel.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameters

Returns a list of all hyperparameter specifications.

is_stationary ()

Returns whether the kernel is stationary.

property n_dims

Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input

Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self
property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.Matern

- Illustration of prior and posterior Gaussian process for different kernels

7.16.11 sklearn.gaussian_process.kernels.PairwiseKernel

class sklearn.gaussian_process.kernels.PairwiseKernel (gamma=1.0, gamma_bounds=(1e-05, 100000.0), metric='linear', pairwise_kernels_kwargs=None)

Wrapper for kernels in sklearn.metrics.pairwise.

A thin wrapper around the functionality of the kernels in sklearn.metrics.pairwise.

Note: Evaluation of eval_gradient is not analytic but numeric and all kernels support only isotropic distances. The parameter gamma is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

Parameters

- gamma [float, default=1.0] Parameter gamma of the pairwise kernel specified by metric. It should be positive.
- gamma_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘gamma’. If set to “fixed”, ‘gamma’ cannot be changed during hyperparameter tuning.
- metric [“linear”, “additive_chi2”, “chi2”, “poly”, “polynomial”, “rbf”, “laplacian”, “sigmoid”, “cosine”] or callable, default=”linear”] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.
- pairwise_kernels_kwargs [dict, default=None] All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.

Attributes

- bounds Returns the log-transformed bounds on the theta.
- hyperparameter_gamma
- hyperparameters Returns a list of all hyperparameter specifications.
- n_dims Returns the number of non-fixed hyperparameters of the kernel.
**requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

### Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import PairwiseKernel

>>> X, y = load_iris(return_X_y=True)
>>> kernel = PairwiseKernel(metric='rbf')
>>> gpc = GaussianProcessClassifier(kernel=kernel, random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9733...
>>> gpc.predict_proba(X[:2, :])
array([[0.8880..., 0.05663..., 0.05532...],
      [0.8676..., 0.07073..., 0.06165...]])
```

### Methods

**__call__**(X[, Y, eval_gradient])
Return the kernel \( k(X, Y) \) and optionally its gradient.

**clone_with_theta**(theta)
Returns a clone of self with given hyperparameters theta.

**diag**(X)
Returns the diagonal of the kernel \( k(X, X) \).

**get_params**(deep)
Get parameters of this kernel.

**is_stationary**()
Returns whether the kernel is stationary.

**set_params**(**params)
Set the parameters of this kernel.

**__call__**(X, Y=None, eval_gradient=False)
Return the kernel \( k(X, Y) \) and optionally its gradient.

**Parameters**

- **X** [ndarray of shape \( (n_{samples}_X, n_{features}) \)] Left argument of the returned kernel \( k(X, Y) \).
- **Y** [ndarray of shape \( (n_{samples}_Y, n_{features}) \), default=None] Right argument of the returned kernel \( k(X, Y) \). If None, \( k(X, X) \) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

**Returns**

- **K** [ndarray of shape \( (n_{samples}_X, n_{samples}_Y) \)] Kernel \( k(X, Y) \).
- **K_gradient** [ndarray of shape \( (n_{samples}_X, n_{samples}_X, n_{dims}) \), optional] The gradient of the kernel \( k(X, Y) \) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds**
Returns the log-transformed bounds on the theta.

**Returns**

---
**bounds** [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(theta)

Returns a clone of self with given hyperparameters theta.

**Parameters**

theta [ndarray of shape (n_dims,)] The hyperparameters

**diag**(X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

**Returns**

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

**get_params**(deep=True)

Get parameters of this kernel.

**Parameters**

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter specifications.

**is_stationary**()

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

**set_params**(**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**

self

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.
Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.12 sklearn.gaussian_process.kernels.Product

class sklearn.gaussian_process.kernels.Product(k1, k2)
The Product kernel takes two kernels $k_1$ and $k_2$ and combines them via

$$k_{\text{prod}}(X, Y) = k_1(X, Y) \times k_2(X, Y)$$

Note that the __mul__ magic method is overridden, so Product(RBF(), RBF()) is equivalent to using the * operator with RBF() * RBF().

Read more in the User Guide.

New in version 0.18.

Parameters

- **k1** [Kernel] The first base-kernel of the product-kernel
- **k2** [Kernel] The second base-kernel of the product-kernel

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is stationary.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
gpr = GaussianProcessRegressor(kernel=kernel, ... random_state=0).fit(X, y)
gpr.score(X, y)  # should return the R^2 of the regressor
1.0
```

1.41**2 * RBF(length_scale=1)
Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel k(X, Y)

Y [array-like of shape (n_samples_Y, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

gget_params (deep=True)
Get parameters of this kernel.
Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter.

**is_stationary**()

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Returns whether the kernel is stationary.

**set_params**(**params**)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

**self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

**theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.13 sklearn.gaussian_process.kernels.RBF

**class sklearn.gaussian_process.kernels.RBF** *(length_scale=1.0, length_scale_bounds=1e-05, 100000.0)*

Radial-basis function kernel (aka squared-exponential kernel).

The RBF kernel is a stationary kernel. It is also known as the “squared exponential” kernel. It is parameterized by a length scale parameter \( l > 0 \), which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs \( X \) (anisotropic variant of the kernel). The kernel is given by:

\[
k(x_i, x_j) = \exp\left(-\frac{d(x_i, x_j)^2}{2l^2}\right)
\]

where \( l \) is the length scale of the kernel and \( d(\cdot, \cdot) \) is the Euclidean distance. For advice on how to set the length scale parameter, see e.g. [1].

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth. See [2], Chapter 4, Section 4.2, for further details of the RBF kernel.
Read more in the *User Guide*.

New in version 0.18.

**Parameters**

- **length_scale** 
  [float or ndarray of shape (n_features,), default=1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

- **length_scale_bounds** 
  [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.

**Attributes**

- **anisotropic**

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_length_scale**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.

- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**References**

**Examples**

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import RBF

>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * RBF(1.0)
>>> gpc = GaussianProcessClassifier(kernel=kernel, 
... random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...

>>> gpc.predict_proba(X[:2,:])
array([[0.8354..., 0.03228..., 0.1322...],
      [0.7906..., 0.0652..., 0.1441...]])
```
## Methods

<table>

</tr>
</tbody>
</table>

**__call__**(X, Y=None, eval_gradient=False)  
Return the kernel $k(X, Y)$ and optionally its gradient.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel $k(X, Y)$
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel $k(X, Y)$. If None, $k(X, X)$ if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

**Returns**

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel $k(X, Y)$
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel $k(X, X)$ with respect to the log of the kernel hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- **bounds** [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)  
Returns a clone of self with given hyperparameters theta.

**Parameters**

- **theta** [ndarray of shape (n_dims,)] The hyperparameters

diag(X)  
Returns the diagonal of the kernel $k(X, X)$.

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel $k(X, Y)$

**Returns**

- **K_diag** [ndarray of shape (n_samples_X,)] Diagonal of kernel $k(X, X)$
**get_params** *(deep=True)*
Get parameters of this kernel.

**Parameters**

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [dict] Parameter names mapped to their values.

**property hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary** *
Returns whether the kernel is stationary.

**property n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

**set_params** (**params**)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form 
<component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**

self

**property theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

*theta* [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

**Examples using sklearn.gaussian_process.kernels.RBF**

- Plot classification probability
- Classifier comparison
- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Gaussian process classification (GPC) on iris dataset
- Illustration of prior and posterior Gaussian process for different kernels
- Probabilistic predictions with Gaussian process classification (GPC)
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian Processes regression: basic introductory example
Gaussian process regression (GPR) on Mauna Loa CO2 data.

\section*{Rational Quadratic kernel}

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different characteristic length scales. It is parameterized by a length scale parameter \( l > 0 \) and a scale mixture parameter \( \alpha > 0 \). Only the isotropic variant where length_scale \( l \) is a scalar is supported at the moment. The kernel is given by:

\[ k(x_i, x_j) = \left( 1 + \frac{d(x_i, x_j)^2}{2\alpha l^2} \right)^{-\alpha} \]

where \( \alpha \) is the scale mixture parameter, \( l \) is the length scale of the kernel and \( d(\cdot, \cdot) \) is the Euclidean distance. For advice on how to set the parameters, see e.g. \cite{1}.

Read more in the \textit{User Guide}.

New in version 0.18.

\begin{verbatim}
Parameters

length_scale [float > 0, default=1.0] The length scale of the kernel.
alpha [float > 0, default=1.0] Scale mixture parameter
length_scale_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.
alpha_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘alpha’. If set to “fixed”, ‘alpha’ cannot be changed during hyperparameter tuning.

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_alpha

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.
n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.
\end{verbatim}

[1]

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import Matern

>>> X, y = load_iris(return_X_y=True)
>>> kernel = Matern(length_scale=1.0, alpha=1.5)
>>> gpc = GaussianProcessClassifier(kernel=kernel,
...                                 random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9733...
>>> gpc.predict_proba(X[:2,:])
array([[0.8881..., 0.0566..., 0.05518...],
       [0.8678..., 0.0707..., 0.0614...]])
```

Methods

```
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

__call__(X=Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns
bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters
theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns
K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.
Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.RationalQuadratic

• Illustration of prior and posterior Gaussian process for different kernels
• Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.16.15 sklearn.gaussian_process.kernels.Sum
class sklearn.gaussian_process.kernels.Sum(k1, k2)
The Sum kernel takes two kernels $k_1$ and $k_2$ and combines them via

$$k_{\text{sum}}(X, Y) = k_1(X, Y) + k_2(X, Y)$$

Note that the __add__ magic method is overridden, so Sum(RBF(), RBF()) is equivalent to using the + operator with RBF() + RBF().

Read more in the User Guide.
New in version 0.18.

Parameters

k1 [Kernel] The first base-kernel of the sum-kernel

k2 [Kernel] The second base-kernel of the sum-kernel

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is stationary.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import RBF, Sum, ConstantKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = Sum(ConstantKernel(2), RBF())
>>> gpr = GaussianProcessRegressor(kernel=kernel, ... random_state=0).fit(X, y)
>>> gpr.score(X, y)
1.0
>>> kernel
1.41**2 + RBF(length_scale=1)
```
Methods

`__call__(X[, Y, eval_gradient])`  
Return the kernel $k(X, Y)$ and optionally its gradient.

`clone_with_theta(theta)`  
Returns a clone of self with given hyperparameters theta.

`diag(X)`  
Returns the diagonal of the kernel $k(X, X)$.

`get_params([deep])`  
Get parameters of this kernel.

`is_stationary()`  
Returns whether the kernel is stationary.

`set_params(**params)`  
Set the parameters of this kernel.

`__call__(X[, Y, eval_gradient])`  
Return the kernel $k(X, Y)$ and optionally its gradient.

Parameters

- **X** [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel $k(X, Y)$
- **Y** [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel $k(X, Y)$. If None, $k(X, X)$ is evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

Returns

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel $k(X, Y)$
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel $k(X, X)$ with respect to the log of the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

`property bounds`  
Returns the log-transformed bounds on the theta.

`clone_with_theta(theta)`  
Returns a clone of self with given hyperparameters theta.

Parameters

- **theta** [ndarray of shape (n_dims,)] The hyperparameters

`diag(X)`  
Returns the diagonal of the kernel $k(X, X)$.

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

- **X** [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

- **K_diag** [ndarray of shape (n_samples_X,)] Diagonal of kernel $k(X, X)$
Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

```
property hyperparameters

Returns a list of all hyperparameter.
```

```
is_stationary()

Returns whether the kernel is stationary.
```

```
property n_dims

Returns the number of non-fixed hyperparameters of the kernel.
```

```
property requires_vector_input

Returns whether the kernel is stationary.
```

```
set_params(**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

**self**
```

property theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

**theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel.
```

7.16.16 **sklearn.gaussian_process.kernels.WhiteKernel**

**class sklearn.gaussian_process.kernels.WhiteKernel**(noise_level=1.0,
noise_level_bounds=1e-05,
100000.0)

White kernel.

The main use-case of this kernel is as part of a sum-kernel where it explains the noise of the signal as independently and identically normally-distributed. The parameter noise_level equals the variance of this noise.

\[ k(x_1, x_2) = noise\_level \text{ if } x_i == x_j \text{ else } 0 \]

Read more in the **User Guide**.

New in version 0.18.

**Parameters**

**noise_level** [float, default=1.0] Parameter controlling the noise level (variance)
noise_level_bounds  [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘noise_level’. If set to “fixed”, ‘noise_level’ cannot be changed during hyperparameter tuning.

Attributes

bounds  Returns the log-transformed bounds on the theta.

hyperparameter_noise_level

hyperparameters  Returns a list of all hyperparameter specifications.

n_dims  Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input  Whether the kernel works only on fixed-length feature vectors.

theta  Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel(noise_level=0.5)
>>> gpr = GaussianProcessRegressor(kernel=kernel, ...random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:2, :], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

Methods

___call___(X, Y, eval_gradient)

Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)

Returns a clone of self with given hyperparameters theta.

diag(X)

Returns the diagonal of the kernel k(X, X).

get_params([deep])

Get parameters of this kernel.

is_stationary()

Returns whether the kernel is stationary.

set_params(**params)

Set the parameters of this kernel.

___call__(X, Y=None, eval_gradient=False)

Return the kernel k(X, Y) and optionally its gradient.

Parameters

X  [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel k(X, Y)

Y  [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.

eval_gradient  [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns
K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
    Returns the log-transformed bounds on the theta.

    Returns

    bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (theta)
    Returns a clone of self with given hyperparameters theta.

    Parameters

    theta [ndarray of shape (n_dims,)] The hyperparameters

diag (X)
    Returns the diagonal of the kernel k(X, X).

    The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

    Parameters

    X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

    Returns

    K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
    Get parameters of this kernel.

    Parameters

    deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns

    params [dict] Parameter names mapped to their values.

property hyperparameters
    Returns a list of all hyperparameter specifications.

is_stationary ()
    Returns whether the kernel is stationary.

property n_dims
    Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
    Whether the kernel works only on fixed-length feature vectors.

set_params (**params)
    Set the parameters of this kernel.

    The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

    Returns
**self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

**Examples using sklearn.gaussian_process.kernels.WhiteKernel**

- Comparison of kernel ridge and Gaussian process regression
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

## 7.17 sklearn.impute: Impute

Transformers for missing value imputation

**User guide:** See the Imputation of missing values section for further details.

| sklearn.impute.SimpleImputer(**kwargs) | Imputation transformer for completing missing values. |
| sklearn.impute.IterativeImputer([estimator, ...]) | Multivariate imputer that estimates each feature from all the others. |
| sklearn.impute.MissingIndicator(**kwargs) | Binary indicators for missing values. |
| sklearn.impute.KNNImputer(**kwargs) | Imputation for completing missing values using k-Nearest Neighbors. |

### 7.17.1 sklearn.impute.SimpleImputer

**class** sklearn.impute.SimpleImputer(**kwargs)**

Imputation transformer for completing missing values.

Read more in the *User Guide*.

New in version 0.20: SimpleImputer replaces the previous sklearn.preprocessing.Imputer estimator which is now removed.

**Parameters**

- **missing_values** [int, float, str, np.nan or None, default=np.nan] The placeholder for the missing values. All occurrences of missing_values will be imputed. For pandas’ dataframes with nullable integer dtypes with missing values, missing_values should be set to np.nan, since pd.NA will be converted to np.nan.

- **strategy** [string, default=’mean’] The imputation strategy.

  - If “mean”, then replace missing values using the mean along each column. Can only be used with numeric data.
• If “median”, then replace missing values using the median along each column. Can only be used with numeric data.
• If “most_frequent”, then replace missing using the most frequent value along each column. Can be used with strings or numeric data.
• If “constant”, then replace missing values with fill_value. Can be used with strings or numeric data.

New in version 0.20: strategy="constant" for fixed value imputation.

**fill_value** [string or numerical value, default=None] When strategy == “constant”, fill_value is used to replace all occurrences of missing_values. If left to the default, fill_value will be 0 when imputing numerical data and “missing_value” for strings or object data types.

**verbose** [integer, default=0] Controls the verbosity of the imputer.

**copy** [boolean, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if copy=False:
• If X is not an array of floating values;
• If X is encoded as a CSR matrix;
• If add_indicator=True.

**add_indicator** [boolean, default=False] If True, a MissingIndicator transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

**Attributes**

**statistics_** [array of shape (n_features,)] The imputation fill value for each feature. Computing statistics can result in np.nan values. During transform, features corresponding to np.nan statistics will be discarded.

**indicator_** [MissingIndicator] Indicator used to add binary indicators for missing values. None if add_indicator is False.

See also:

**IterativeImputer** Multivariate imputation of missing values.

**Notes**

Columns which only contained missing values at fit are discarded upon transform if strategy is not “constant”.
Examples

```python
>>> import numpy as np
>>> from sklearn.impute import SimpleImputer

>>> imp_mean = SimpleImputer(missing_values=np.nan, strategy='mean')
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
SimpleImputer()

>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> print(imp_mean.transform(X))
[[ 7.  2.  3.]
 [ 4.  3.5  6.]
 [10.  3.5  9.]]
```

**fit** *(X, y=None)*

Fit the imputer on X.

Parameters

- **X** *(array-like, sparse matrix), shape (n_samples, n_features)*: Input data, where n_samples is the number of samples and n_features is the number of features.

Returns

- **self** *(SimpleImputer)*

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** *(array-like of shape (n_samples, n_features))*: Input samples.
- **y** *(array-like of shape (n_samples,) or (n_samples, n_outputs), default=None)*: Target values (None for unsupervised transformations).

**fit_params** *(dict)*: Additional fit parameters.

Returns

- **X_new** *(ndarray array of shape (n_samples, n_features_new))*: Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters

- **deep** *(bool)*: If True, will return the parameters for this estimator and contained subobjects that are estimators.
deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

inverse_transform(X)
Convert the data back to the original representation.

Inverts the transform operation performed on an array. This operation can only be performed after SimpleImputer is instantiated with add_indicator=True.

Note that inverse_transform can only invert the transform in features that have binary indicators for missing values. If a feature has no missing values at fit time, the feature won’t have a binary indicator, and the imputation done at transform time won’t be inverted.

New in version 0.24.

Parameters

X  [array-like of shape (n_samples, n_features + n_features_missing_indicator)] The imputed data to be reverted to original data. It has to be an augmented array of imputed data and the missing indicator mask.

Returns

X_original  [ndarray of shape (n_samples, n_features)] The original X with missing values as it was prior to imputation.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

transform(X)
Impute all missing values in X.

Parameters

X  [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

Examples using sklearn.impute.SimpleImputer

- Release Highlights for scikit-learn 0.23
- Combine predictors using stacking
- Permutation Importance vs Random Forest Feature Importance (MDI)
- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
- Column Transformer with Mixed Types
7.17.2 sklearn.impute.IterativeImputer

class sklearn.impute.IterativeImputer(estimator=None, *, missing_values=nan, sample_posterior=False, max_iter=10, tol=0.001, n_nearest_features=None, initial_strategy='mean', imputation_order='ascending', skip_complete=False, min_value=-inf, max_value=inf, verbose=0, random_state=None, add_indicator=False)

Multivariate imputer that estimates each feature from all the others.

A strategy for imputing missing values by modeling each feature with missing values as a function of other features in a round-robin fashion.

Read more in the User Guide.

New in version 0.21.

Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_iterative_imputer:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer
# noqa
```  
```python
>>> # now you can import normally from sklearn.impute
>>> from sklearn.impute import IterativeImputer
```

Parameters

estimator [estimator object, default=BayesianRidge()] The estimator to use at each step of the round-robin imputation. If sample_posterior is True, the estimator must support return_std in its predict method.

missing_values [int, np.nan, default=np.nan] The placeholder for the missing values. All occurrences of missing_values will be imputed. For pandas' dataframes with nullable integer dtypes with missing values, missing_values should be set to np.nan, since pd.NA will be converted to np.nan.

sample_posterior [boolean, default=False] Whether to sample from the (Gaussian) predictive posterior of the fitted estimator for each imputation. Estimator must support return_std in its predict method if set to True. Set to True if using IterativeImputer for multiple imputations.

max_iter [int, default=10] Maximum number of imputation rounds to perform before returning the imputations computed during the final round. A round is a single imputation of each feature with missing values. The stopping criterion is met once max(abs(X_t - X_{t-1}))/max(abs(X[known_vals])) < tol, where X_t is X at iteration t. Note that early stopping is only applied if sample_posterior=False.

tol [float, default=1e-3] Tolerance of the stopping condition.

n_nearest_features [int, default=None] Number of other features to use to estimate the missing values of each feature column. Nearness between features is measured using the absolute correlation coefficient between each feature pair (after initial imputation). To ensure coverage of features throughout the imputation process, the neighbor features are not necessarily nearest, but are drawn with probability proportional to correlation for each imputed target feature. Can provide significant speed-up when the number of features is huge. If None, all features will be used.
**initial_strategy** [str, default='mean'] Which strategy to use to initialize the missing values. Same as the strategy parameter in SimpleImputer. Valid values: (“mean”, “median”, “most_frequent”, or “constant”).

**imputation_order** [str, default='ascending'] The order in which the features will be imputed. Possible values:

- **ascending** From features with fewest missing values to most.
- **descending** From features with most missing values to fewest.
- **roman** Left to right.
- **arabic** Right to left.
- **random** A random order for each round.

**skip_complete** [boolean, default=False] If True then features with missing values during transform which did not have any missing values during fit will be imputed with the initial imputation method only. Set to True if you have many features with no missing values at both fit and transform time to save compute.

**min_value** [float or array-like of shape (n_features,), default=-np.inf] Minimum possible imputed value. Broadcast to shape (n_features,) if scalar. If array-like, expects shape (n_features,), one min value for each feature. The default is -np.inf. Changed in version 0.23: Added support for array-like.

**max_value** [float or array-like of shape (n_features,), default=np.inf] Maximum possible imputed value. Broadcast to shape (n_features,) if scalar. If array-like, expects shape (n_features,), one max value for each feature. The default is np.inf. Changed in version 0.23: Added support for array-like.

**verbose** [int, default=0] Verbosity flag, controls the debug messages that are issued as functions are evaluated. The higher, the more verbose. Can be 0, 1, or 2.

**random_state** [int, RandomState instance or None, default=None] The seed of the pseudo random number generator to use. Randomizes selection of estimator features if n_nearest_features is not None, the imputation_order if random, and the sampling from posterior if sample_posterior is True. Use an integer for determinism. See the Glossary.

**add_indicator** [boolean, default=False] If True, a MissingIndicator transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

**Attributes**

- **initial_imputer_** [object of type SimpleImputer] Imputer used to initialize the missing values.

- **imputation_sequence_** [list of tuples] Each tuple has (feat_idx, neighbor_feat_idx, estimator), where feat_idx is the current feature to be imputed, neighbor_feat_idx is the array of other features used to impute the current feature, and estimator is the trained estimator used for the imputation. Length is self.n_features_with_missing_ * self.n_iter_.

- **n_iter_** [int] Number of iteration rounds that occurred. Will be less than self.max_iter if early stopping criterion was reached.
n_features_with_missing_ [int] Number of features with missing values.

indicator_ [MissingIndicator] Indicator used to add binary indicators for missing values.
None if add_indicator is False.

random_state_ [RandomState instance] RandomState instance that is generated either from a
seed, the random number generator or by np.random.

See also:

SimpleImputer  Univariate imputation of missing values.

Notes

To support imputation in inductive mode we store each feature’s estimator during the fit phase, and predict
without refitting (in order) during the transform phase.
Features which contain all missing values at fit are discarded upon transform.

[1],[2]

Examples

```python
>>> import numpy as np
>>> from sklearn.experimental import enable_iterative_imputer
>>> from sklearn.impute import IterativeImputer

>>> imp_mean = IterativeImputer(random_state=0)
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
IterativeImputer(random_state=0)

>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> imp_mean.transform(X)
array([[6.9584..., 2. , 3. ],
       [4. , 2.6000..., 6. ],
       [10. , 4.9999..., 9. ]])
```

Methods

- `fit(X[, y])`  
  Fits the imputer on X and return self.
- `fit_transform(X[, y])`  
  Fits the imputer on X and return the transformed X.
- `get_params([deep])`  
  Get parameters for this estimator.
- `set_params(**params)`  
  Set the parameters of this estimator.
- `transform(X)`  
  Imputes all missing values in X.

**fit (X, y=None)**

Fits the imputer on X and return self.

**Parameters**

- **X**  
  [array-like, shape (n_samples, n_features)] Input data, where “n_samples” is the number
  of samples and “n_features” is the number of features.
Returns

self [object] Returns self.

**fit_transform** (*X, y=None*)
Fits the imputer on X and return the transformed X.

**Parameters**

* X [array-like, shape (n_samples, n_features)] Input data, where “n_samples” is the number of samples and “n_features” is the number of features.

* y [ignored.]

**Returns**

* Xt [array-like, shape (n_samples, n_features)] The imputed input data.

**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**

* deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

* params [dict] Parameter names mapped to their values.

**set_params** (**params**)
Set the parameters of this estimator.

* **params** [dict] Estimator parameters.

**Returns**

* self [estimator instance] Estimator instance.

**transform** (*X*)
Imputes all missing values in X.

Note that this is stochastic, and that if random_state is not fixed, repeated calls, or permuted input, will yield different results.

**Parameters**

* X [array-like of shape (n_samples, n_features)] The input data to complete.

**Returns**

* Xt [array-like, shape (n_samples, n_features)] The imputed input data.
Examples using `sklearn.impute.IterativeImputer`

- *Imputing missing values with variants of IterativeImputer*
- *Imputing missing values before building an estimator*

### 7.17.3 `sklearn.impute.MissingIndicator`

```python
class sklearn.impute.MissingIndicator(**kwargs)
```

Binary indicators for missing values.

Note that this component typically should not be used in a vanilla Pipeline consisting of transformers and a classifier, but rather could be added using a FeatureUnion or ColumnTransformer.

Read more in the User Guide.

New in version 0.20.

**Parameters**

- `missing_values` [int, float, string, np.nan or None, default=np.nan] The placeholder for the missing values. All occurrences of `missing_values` will be imputed. For pandas' dataframes with nullable integer dtypes with missing values, `missing_values` should be set to `np.nan`, since `pd.NA` will be converted to `np.nan`.

- `features` [{‘missing-only’, ‘all’}, default=’missing-only’] Whether the imputer mask should represent all or a subset of features.
  - If ‘missing-only’ (default), the imputer mask will only represent features containing missing values during fit time.
  - If ‘all’, the imputer mask will represent all features.

- `sparse` [bool or ‘auto’, default=’auto’] Whether the imputer mask format should be sparse or dense.
  - If ‘auto’ (default), the imputer mask will be of same type as input.
  - If True, the imputer mask will be a sparse matrix.
  - If False, the imputer mask will be a numpy array.

- `error_on_new` [bool, default=True] If True, transform will raise an error when there are features with missing values in transform that have no missing values in fit. This is applicable only when `features='missing-only'`.

**Attributes**

- `features_` [ndarray, shape (n_missing_features,) or (n_features,)] The features indices which will be returned when calling `transform`. They are computed during `fit`. For `features='all'`, it is to range(n_features).
Examples

```python
>>> import numpy as np
>>> from sklearn.impute import MissingIndicator

>>> X1 = np.array([[np.nan, 1, 3],
                  [4, 0, np.nan],
                  [8, 1, 0]])
>>> X2 = np.array([[5, 1, np.nan],
                  [np.nan, 2, 3],
                  [2, 4, 0]])

>>> indicator = MissingIndicator()
>>> indicator.fit(X1)
MissingIndicator()
>>> X2_tr = indicator.transform(X2)
>>> X2_tr
array([[False,  True],
        [ True, False],
        [False, False]])
```

`fit(X, y=None)`

Fit the transformer on X.

Parameters

- `X` [[array-like, sparse matrix], shape (n_samples, n_features)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

`fit_transform(X, y=None)`

Generate missing values indicator for X.

Parameters

- `X` [[array-like, sparse matrix], shape (n_samples, n_features)] The input data to complete.

Returns

- `Xt` [ndarray or sparse matrix], shape (n_samples, n_features) or (n_samples, n_features_with_missing)] The missing indicator for input data. The data type of `Xt` will be boolean.

`get_params(deep=True)`

Get parameters for this estimator.

Parameters
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

### set_params(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

### transform(X)

Generate missing values indicator for X.

Parameters

**X** [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

Returns

**Xt** [{ndarray or sparse matrix}, shape (n_samples, n_features) or (n_samples, n_features_with_missing)] The missing indicator for input data. The data type of Xt will be boolean.

#### 7.17.4 sklearn.impute.KNNImputer

class sklearn.impute.KNNImputer(**kwargs)**

Imputation for completing missing values using k-Nearest Neighbors.

Each sample’s missing values are imputed using the mean value from n_neighbors nearest neighbors found in the training set. Two samples are close if the features that neither is missing are close.

Read more in the *User Guide*.

New in version 0.22.

Parameters

**missing_values** [int, float, str, np.nan or None, default=np.nan] The placeholder for the missing values. All occurrences of missing_values will be imputed. For pandas’ dataframes with nullable integer dtypes with missing values, missing_values should be set to np.nan, since pd.NA will be converted to np.nan.

**n_neighbors** [int, default=5] Number of neighboring samples to use for imputation.

**weights** [{‘uniform’, ‘distance’} or callable, default=‘uniform’] Weight function used in prediction. Possible values:

* ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
* ‘distance’: weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
• callable : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

**metric** [{’nan_euclidean’} or callable, default=’nan_euclidean’] Distance metric for searching neighbors. Possible values:

• ’nan_euclidean’

• callable : a user-defined function which conforms to the definition of _pairwise_callable(X, Y, metric, **kwds). The function accepts two arrays, X and Y, and a missing_values keyword in kwds and returns a scalar distance value.

**copy** [bool, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible.

**add_indicator** [bool, default=False] If True, a MissingIndicator transform will stack onto the output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

Attributes

indicator_ [MissingIndicator] Indicator used to add binary indicators for missing values. None if add_indicator is False.

Examples

```python
>>> import numpy as np
>>> from sklearn.impute import KNNImputer
>>> X = [[1, 2, np.nan], [3, 4, 3], [np.nan, 6, 5], [8, 8, 7]]
>>> imputer = KNNImputer(n_neighbors=2)
>>> imputer.fit_transform(X)
array([[1., 2., 4. ],
       [3., 4., 3. ],
       [5.5, 6., 5. ],
       [8., 8., 7. ]])
```

Methods

```python
fit(X[, y])                     Fit the imputer on X.
fit_transform(X[, y])          Fit to data, then transform it.
get_params([deep])             Get parameters for this estimator.
set_params(**params)           Set the parameters of this estimator.
transform(X)                   Impute all missing values in X.
```

```
7.17. sklearn.impute: Impute
```

2097
Fit the imputer on X.

Parameters

X [array-like shape of (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

Returns

self [object]

fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)

Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Impute all missing values in X.

Parameters

X [array-like of shape (n_samples, n_features)] The input data to complete.

Returns
X [array-like of shape (n_samples, n_output_features)] The imputed dataset.
    n_output_features is the number of features that is not always missing during fit.

Examples using sklearn.impute.KNNImputer

- Release Highlights for scikit-learn 0.22
- Imputing missing values before building an estimator

7.18 sklearn.inspection: Inspection

The sklearn.inspection module includes tools for model inspection.

    inspection.partial_dependence(estimator, X, ...)  # Partial dependence of features.

    inspection.permutation_importance(estimator, X, ...)  # Permutation importance for feature evaluation [BRE].

7.18.1 sklearn.inspection.partial_dependence

sklearn.inspection.partial_dependence (estimator, X, features, *, response_method='auto',
    percentiles=(0.05, 0.95), grid_resolution=100,
    method='auto', kind='legacy')

Partial dependence of features.

Partial dependence of a feature (or a set of features) corresponds to the average response of an estimator for each possible value of the feature.

Read more in the User Guide.

Warning: For GradientBoostingClassifier and GradientBoostingRegressor, the 'recursion' method (used by default) will not account for the init predictor of the boosting process. In practice, this will produce the same values as 'brute' up to a constant offset in the target response, provided that init is a constant estimator (which is the default). However, if init is not a constant estimator, the partial dependence values are incorrect for 'recursion' because the offset will be sample-dependent. It is preferable to use the 'brute' method. Note that this only applies to GradientBoostingClassifier and GradientBoostingRegressor, not to HistGradientBoostingClassifier and HistGradientBoostingRegressor.

Parameters

    estimator [BaseEstimator] A fitted estimator object implementing predict, predict_proba, or decision_function. Multioutput-multiclass classifiers are not supported.

    X [(array-like or dataframe) of shape (n_samples, n_features)] X is used to generate a grid of values for the target features (where the partial dependence will be evaluated), and also to generate values for the complement features when the method is ‘brute’.

    features [array-like of {int, str}] The feature (e.g. [0]) or pair of interacting features (e.g. [(0, 1)]) for which the partial dependency should be computed.
response_method [{‘auto’, ‘predict_proba’, ‘decision_function’}, default=’auto’] Specifies whether to use predict_proba or decision_function as the target response. For regressors this parameter is ignored and the response is always the output of predict. By default, predict_proba is tried first and we revert to decision_function if it doesn’t exist. If method is ‘recursion’, the response is always the output of decision_function.

percentiles [tuple of float, default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the grid. Must be in [0, 1].

grid_resolution [int, default=100] The number of equally spaced points on the grid, for each target feature.

method [{‘auto’, ‘recursion’, ‘brute’}, default=‘auto’] The method used to calculate the averaged predictions:

- ‘recursion’ is only supported for some tree-based estimators (namely GradientBoostingClassifier, GradientBoostingRegressor, HistGradientBoostingClassifier, HistGradientBoostingRegressor, DecisionTreeRegressor, RandomForestRegressor, ) when kind=‘average’. This is more efficient in terms of speed. With this method, the target response of a classifier is always the decision function, not the predicted probabilities. Since the ‘recursion’ method implicitly computes the average of the Individual Conditional Expectation (ICE) by design, it is not compatible with ICE and thus kind must be ‘average’.

- ‘brute’ is supported for any estimator, but is more computationally intensive.

- ‘auto’: the ‘recursion’ is used for estimators that support it, and ‘brute’ is used otherwise.

Please see this note for differences between the ‘brute’ and ‘recursion’ method.

kind [{‘legacy’, ‘average’, ‘individual’, ‘both’}, default=‘legacy’] Whether to return the partial dependence averaged across all the samples in the dataset or one line per sample or both. See Returns below.

Note that the fast method=‘recursion’ option is only available for kind=‘average’. Plotting individual dependencies requires using the slower method=‘brute’ option.

New in version 0.24.

Deprecated since version 0.24: kind=‘legacy’ is deprecated and will be removed in version 0.26. kind=‘average’ will be the new default. It is intended to migrate from the ndarray output to Bunch output.

Returns

predictions [ndarray or Bunch]

- if kind=‘legacy’, return value is ndarray of shape (n_outputs, len(values[0]), len(values[1]), …) The predictions for all the points in the grid, averaged over all samples in X (or over the training data if method is ‘recursion’).

- if kind=‘individual’, ‘average’ or ‘both’, return value is Bunch Dictionary-like object, with the following attributes.

  individual [ndarray of shape (n_outputs, n_instances, len(values[0]), len(values[1]), …)] The predictions for all the points in the grid for all samples in X. This is also known as Individual Conditional Expectation (ICE)
average [ndarray of shape (n_outputs, len(values[0]), len(values[1]), ...)] The predictions for all the points in the grid, averaged over all samples in X (or over the training data if method is 'recursion'). Only available when kind='both'.

values [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in values. len(values) == len(features). The size of each array values[j] is either grid_resolution, or the number of unique values in X[:, j], whichever is smaller.

n_outputs corresponds to the number of classes in a multi-class setting, or to the number of tasks for multi-output regression. For classical regression and binary classification n_outputs==1.

values [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in values. len(values) == len(features). The size of each array values[j] is either grid_resolution, or the number of unique values in X[:, j], whichever is smaller. Only available when kind="legacy".

Examples

```python
>>> X = [[0, 0, 2], [1, 0, 0]]
>>> y = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(X, y)
>>> partial_dependence(gb, features=[0], X=X, percentiles=(0, 1), ...
...           grid_resolution=2)
(array([[-4.52..., 4.52...]]), [array([ 0., 1.])])
```

Examples using sklearn.inspection.partial_dependence

- Partial Dependence and Individual Conditional Expectation Plots

7.18.2 sklearn.inspection.permutation_importance

sklearn.inspection.permutation_importance (estimator, X, y, *, scoring=None, n_repeats=5, n_jobs=None, random_state=None, sample_weight=None)

Permutation importance for feature evaluation [BRE].

The estimator is required to be a fitted estimator. X can be the data set used to train the estimator or a hold-out set. The permutation importance of a feature is calculated as follows. First, a baseline metric, defined by scoring, is evaluated on a (potentially different) dataset defined by the X. Next, a feature column from the validation set is permuted and the metric is evaluated again. The permutation importance is defined to be the difference between the baseline metric and metric from permutating the feature column.

Read more in the User Guide.
Parameters

- **estimator** [object] An estimator that has already been fitted and is compatible with `scorer`.
- **X** [ndarray or DataFrame, shape (n_samples, n_features)] Data on which permutation importance will be computed.
- **y** [array-like or None, shape (n_samples, ) or (n_samples, n_classes)] Targets for supervised or None for unsupervised.
- **scoring** [string, callable or None, default=None] Scorer to use. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator’s default scorer is used.
- **n_repeats** [int, default=5] Number of times to permute a feature.
- **n_jobs** [int or None, default=None] Number of jobs to run in parallel. The computation is done by computing permutation score for each columns and parallelized over the columns. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **random_state** [int, RandomState instance, default=None] Pseudo-random number generator to control the permutations of each feature. Pass an int to get reproducible results across function calls. See :term: Glossary <random_state>.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights used in scoring.

New in version 0.24.

Returns

- **result** [Bunch] Dictionary-like object, with the following attributes.
  - **importances_mean** [ndarray, shape (n_features, )] Mean of feature importance over n_repeats.
  - **importances_std** [ndarray, shape (n_features, )] Standard deviation over n_repeats.
  - **importances** [ndarray, shape (n_features, n_repeats)] Raw permutation importance scores.

## 7.18.3 Plotting

`inspection.PartialDependenceDisplay(**kwargs)` Partial Dependence Plot (PDP).

### `sklearn.inspection.PartialDependenceDisplay`

**class sklearn.inspection.PartialDependenceDisplay(**kwargs)**

Partial Dependence Plot (PDP).
This can also display individual partial dependencies which are often referred to as: Individual Condition Expectation (ICE).

It is recommended to use `plot_partial_dependence` to create a `PartialDependenceDisplay`. All parameters are stored as attributes.

**Parameters**

- `pd_results` [list of Bunch] Results of `partial_dependence` for features.
- `features` [list of (int,) or list of (int, int)] Indices of features for a given plot. A tuple of one integer will plot a partial dependence curve of one feature. A tuple of two integers will plot a two-way partial dependence curve as a contour plot.
- `feature_names` [list of str] Feature names corresponding to the indices in `features`.
- `target_idx` [int]
  - In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
  - In a multioutput setting, specifies the task for which the PDPs should be computed. Ignored in binary classification or classical regression settings.
- `pdp_lim` [dict] Global min and max average predictions, such that all plots will have the same scale and y limits. `pdp_lim[1]` is the global min and max for single partial dependence curves. `pdp_lim[2]` is the global min and max for two-way partial dependence curves.
- `kind` [{'average', 'individual', 'both'}, default='average']
  Whether to plot the partial dependence averaged across all the samples in the dataset or one line per sample or both.
A new plot is introduced in scikit-learn version 0.24: the ICE (Individual Conditional Expectation) plot. This plot is an alternative to the traditional PD (Partial Dependence) plot, which is used to visualize the average effect of a predictor variable on the target variable. ICE plots show the effect of a predictor variable on the target variable for each individual in the dataset, whereas PD plots show the average effect across all observations.

The `plotPartialDependence` function can generate either ICE or PD plots, depending on the `kind` parameter:

- `kind='average'` results in the traditional PD plot;
- `kind='individual'` results in the ICE plot.

Note that the fast `method='recursion'` option is only available for `kind='average'`. Plotting individual dependencies requires using the slower `method='brute'` option.

**Attributes**

- `bounding_ax_` [matplotlib Axes or None] If `ax` is an axes or None, the `bounding_ax_` is the axes where the grid of partial dependence plots are drawn. If `ax` is a list of axes or a numpy array of axes, `bounding_ax_` is None.
- `axes_` [ndarray of matplotlib Axes] If `ax` is an axes or None, `axes_[i, j]` is the axes on the i-th row and j-th column. If `ax` is a list of axes, `axes_[i]` is the i-th item in `ax`. Elements that are None correspond to a nonexisting axes in that position.
- `lines_` [ndarray of matplotlib Artists] If `ax` is an axes or None, `lines_[i, j]` is the partial dependence curve on the i-th row and j-th column. If `ax` is a list of axes, `lines_[i]` is the partial dependence curve corresponding to the i-th item in `ax`. Elements that are None correspond to a nonexisting axes or an axes that does not include a line plot.
- `deciles_vlines_` [ndarray of matplotlib LineCollection] If `ax` is an axes or None, `vlines_[i, j]` is the line collection representing the x axis deciles of the i-th row and j-th column. If `ax` is a list of axes, `vlines_[i]` corresponds to the i-th item in `ax`. Elements that are None correspond to a nonexisting axes or an axes that does not include a PDP plot.
- `deciles_hlines_` [ndarray of matplotlib LineCollection] If `ax` is an axes or None, `hlines_[i, j]` is the line collection representing the y axis deciles of the i-th row and j-th column. If `ax` is a list of axes, `hlines_[i]` corresponds to the i-th item in `ax`. Elements that are None correspond to a nonexisting axes or an axes that does not include a 2-way plot.
- `contours_` [ndarray of matplotlib Artists] If `ax` is an axes or None, `contours_[i, j]` is the partial dependence plot on the i-th row and j-th column. If `ax` is a list of axes, `contours_[i]` is the partial dependence plot corresponding to the i-th item in `ax`. Elements that are None correspond to a nonexisting axes or an axes that does not include a contour plot.
- `figure_` [matplotlib Figure] Figure containing partial dependence plots.

**New in version 0.24.**

- `subsample` [float, int or None, default=1000] Sampling for ICE curves when `kind` is ‘individual’ or ‘both’. If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to be used to plot ICE curves. If int, represents the maximum absolute number of samples to use. Note that the full dataset is still used to calculate partial dependence when `kind='both'`.

**Attributes**

- `subsample_` [float, int or None, default=1000] Sampling for ICE curves when `kind` is ‘individual’ or ‘both’. If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to be used to plot ICE curves. If int, represents the maximum absolute number of samples to use.

**New in version 0.24.**

**See also:**

- `partial_dependence` Compute Partial Dependence values.
- `plot_partial_dependence` Plot Partial Dependence.
Methods

plot([ax, n_cols, line_kw, contour_kw]) Plot partial dependence plots.

Parameters

ax [Matplotlib axes or array-like of Matplotlib axes, default=None]

• If a single axis is passed in, it is treated as a bounding axes and a grid of partial dependence plots will be drawn within these bounds. The n_cols parameter controls the number of columns in the grid.

• If an array-like of axes are passed in, the partial dependence plots will be drawn directly into these axes.

• If None, a figure and a bounding axes is created and treated as the single axes case.

n_cols [int, default=3] The maximum number of columns in the grid plot. Only active when ax is a single axes or None.

line_kw [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.plot call. For one-way partial dependence plots.

contour_kw [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.contourf call for two-way partial dependence plots.

Returns

display [PartialDependenceDisplay]

Examples using sklearn.inspection.PartialDependenceDisplay

• Advanced Plotting With Partial Dependence

sklearn.inspection.plot_partial_dependence(...[*, feature_names=None, target=None, response_method='auto', n_cols=3, grid_resolution=100, percentiles=(0.05, 0.95), method='auto', n_jobs=None, verbose=0, line_kw=None, contour_kw=None, ax=None, kind='average', subsample=1000])

Partial dependence (PD) and individual conditional expectation (ICE) plots.

Partial dependence plots, individual conditional expectation plots or an overlay of both of them can be plotted by setting the kind parameter. The len(features) plots are arranged in a grid with n_cols columns. Two-way partial dependence plots are plotted as contour plots. The deciles of the feature values will be shown with tick marks on the x-axes for one-way plots, and on both axes for two-way plots.
Note: `plot_partial_dependence` does not support using the same axes with multiple calls. To plot the partial dependence for multiple estimators, please pass the axes created by the first call to the second call:

```python
>>> from sklearn.inspection import plot_partial_dependence
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.ensemble import RandomForestRegressor

>>> X, y = make_friedman1()
>>> est1 = LinearRegression().fit(X, y)
>>> est2 = RandomForestRegressor().fit(X, y)
>>> disp1 = plot_partial_dependence(est1, X, [1, 2])
>>> disp2 = plot_partial_dependence(est2, X, [1, 2],
... ax=disp1.axes_)
```

Warning: For `GradientBoostingClassifier` and `GradientBoostingRegressor`, the 'recursion' method (used by default) will not account for the init predictor of the boosting process. In practice, this will produce the same values as 'brute' up to a constant offset in the target response, provided that init is a constant estimator (which is the default). However, if init is not a constant estimator, the partial dependence values are incorrect for 'recursion' because the offset will be sample-dependent. It is preferable to use the 'brute' method. Note that this only applies to `GradientBoostingClassifier` and `GradientBoostingRegressor`, not to `HistGradientBoostingClassifier` and `HistGradientBoostingRegressor`.

Parameters

- **estimator** [BaseEstimator] A fitted estimator object implementing `predict`, `predict_proba`, or `decision_function`. Multioutput-multiclass classifiers are not supported.

- **X** [array-like or dataframe of shape (n_samples, n_features)] X is used to generate a grid of values for the target features (where the partial dependence will be evaluated), and also to generate values for the complement features when the method is 'brute'.

- **features** [list of {int, str, pair of int, pair of str}] The target features for which to create the PDPs. If features[i] is an integer or a string, a one-way PDP is created; if features[i] is a tuple, a two-way PDP is created (only supported with kind='average'). Each tuple must be of size 2. if any entry is a string, then it must be in feature_names.

- **feature_names** [array-like of shape (n_features,), dtype=str, default=None] Name of each feature; feature_names[i] holds the name of the feature with index i. By default, the name of the feature corresponds to their numerical index for NumPy array and their column name for pandas dataframe.

- **target** [int, default=None]
  - In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
  - In a multioutput setting, specifies the task for which the PDPs should be computed. Ignored in binary classification or classical regression settings.

- **response_method** [{‘auto’, ‘predict_proba’, ‘decision_function’}, default='auto'] Specifies whether to use `predict_proba` or `decision_function` as the target response. For regressors
this parameter is ignored and the response is always the output of `predict`. By default, `predict_proba` is tried first and we revert to `decision_function` if it doesn’t exist. If `method` is 'recursion', the response is always the output of `decision_function`.

**n_cols** [int, default=3] The maximum number of columns in the grid plot. Only active when `ax` is a single axis or None.

**grid_resolution** [int, default=100] The number of equally spaced points on the axes of the plots, for each target feature.

**percentiles** [tuple of float, default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the PDP axes. Must be in [0, 1].

**method** [str, default='auto'] The method used to calculate the averaged predictions:

- 'recursion' is only supported for some tree-based estimators (namely `GradientBoostingClassifier`, `GradientBoostingRegressor`, `HistGradientBoostingClassifier`, `HistGradientBoostingRegressor`, `DecisionTreeRegressor`, `RandomForestRegressor` but is more efficient in terms of speed. With this method, the target response of a classifier is always the decision function, not the predicted probabilities. Since the 'recursion' method implicitly computes the average of the ICEs by design, it is not compatible with ICE and thus `kind` must be 'average'.

- 'brute' is supported for any estimator, but is more computationally intensive.

- 'auto': the 'recursion' is used for estimators that support it, and 'brute' is used otherwise.

Please see this note for differences between the 'brute' and 'recursion' method.

**n_jobs** [int, default=None] The number of CPUs to use to compute the partial dependences. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**verbose** [int, default=0] Verbose output during PD computations.

**line_kw** [dict, default=None] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

**contour_kw** [dict, default=None] Dict with keywords passed to the `matplotlib.pyplot.contourf` call. For two-way partial dependence plots.

**ax** [Matplotlib axes or array-like of Matplotlib axes, default=None]

- If a single axis is passed in, it is treated as a bounding axes and a grid of partial dependence plots will be drawn within these bounds. The `n_cols` parameter controls the number of columns in the grid.

- If an array-like of axes are passed in, the partial dependence plots will be drawn directly into these axes.

- If None, a figure and a bounding axes is created and treated as the single axes case.

New in version 0.22.

**kind** [‘average’, ‘individual’, ‘both’], default=’average’

Whether to plot the partial dependence averaged across all the samples in the dataset or one line per sample or both.

- `kind='average'` results in the traditional PD plot;
• kind='individual' results in the ICE plot.

Note that the fast method='recursion' option is only available for kind='average'. Plotting individual dependencies requires using the slower method='brute' option.

New in version 0.24.

subsample [float, int or None, default=1000] Sampling for ICE curves when kind is ‘individual’ or ‘both’. If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to be used to plot ICE curves. If int, represents the absolute number samples to use.

Note that the full dataset is still used to calculate averaged partial dependence when kind='both'.

New in version 0.24.

Returns

display [PartialDependenceDisplay]

See also:

partial_dependence Compute Partial Dependence values.
PartialDependenceDisplay Partial Dependence visualization.

Examples

```python
generate from sklearn.datasets import make_friedman1
generate from sklearn.ensemble import GradientBoostingRegressor
generate X, y = make_friedman1()
generate clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
generate plot_partial_dependence(clf, X, [0, (0, 1)])
```

7.19 sklearn.isotonic: Isotonic regression

User guide: See the Isotonic regression section for further details.
7.19.1 sklearn.isotonic.IsotonicRegression

class sklearn.isotonic.IsotonicRegression(**kwargs)

Isotonic regression model.

Read more in the User Guide.

New in version 0.13.

Parameters

- y_min [float, default=None] Lower bound on the lowest predicted value (the minimum value may still be higher). If not set, defaults to -inf.
- y_max [float, default=None] Upper bound on the highest predicted value (the maximum may still be lower). If not set, defaults to +inf.
- increasing [bool or ‘auto’, default=True] Determines whether the predictions should be constrained to increase or decrease with X. ‘auto’ will decide based on the Spearman correlation estimate’s sign.
- out_of_bounds [(‘nan’, ‘clip’, ‘raise’), default=’nan’] Handles how X values outside of the training domain are handled during prediction.
  - ‘nan’, predictions will be NaN.
  - ‘clip’, predictions will be set to the value corresponding to the nearest train interval endpoint.
  - ‘raise’, a ValueError is raised.

Attributes

- X_min_ [float] Minimum value of input array X for left bound.
- X_max_ [float] Maximum value of input array X for right bound.
- X_thresholds_ [ndarray of shape (n_thresholds,)] Unique ascending X values used to interpolate the y = f(X) monotonic function.
  
  New in version 0.24.
- y_thresholds_ [ndarray of shape (n_thresholds,)] De-duplicated y values suitable to interpolate the y = f(X) monotonic function.
  
  New in version 0.24.
- f_ [function] The stepwise interpolating function that covers the input domain X.
- increasing_ [bool] Inferred value for increasing.

Notes

Ties are broken using the secondary method from Leeuw, 1977.
References

Isotone Optimization in R : Pool-Adjacent-Violators Algorithm (PAVA) and Active Set Methods Leeuw, Hornik, Mair Journal of Statistical Software 2009

Correctness of Kruskal’s algorithms for monotone regression with ties Leeuw, Psychometrica, 1977

Examples

```python
>>> from sklearn.datasets import make_regression
>>> from sklearn.isotonic import IsotonicRegression
>>> X, y = make_regression(n_samples=10, n_features=1, random_state=41)
>>> iso_reg = IsotonicRegression().fit(X, y)
>>> iso_reg.predict([.1, .2])
array([1.8628..., 3.7256...])
```

Methods

```
fit(X, y[, sample_weight])          Fit the model using X, y as training data.
fit_transform(X[, y])              Fit to data, then transform it.
get_params([deep])                 Get parameters for this estimator.
predict(T)                         Predict new data by linear interpolation.
score(X, y[, sample_weight])       Return the coefficient of determination $R^2$ of the prediction.
set_params(**params)               Set the parameters of this estimator.
transform(T)                       Transform new data by linear interpolation
```

**fit** (X, y, sample_weight=None)
Fit the model using X, y as training data.

Parameters

- **X** [array-like of shape (n_samples,) or (n_samples, 1)] Training data.
  
  Changed in version 0.24: Also accepts 2d array with 1 feature.

- **y** [array-like of shape (n_samples,)] Training target.

- **sample_weight** [array-like of shape (n_samples,), default=None] Weights. If set to None, all weights will be set to 1 (equal weights).

Returns

- **self** [object] Returns an instance of self.
Notes

X is stored for future use, as `transform` needs X to interpolate new input data.

`fit_transform`(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

`get_params`(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

`predict`(T)

Predict new data by linear interpolation.

Parameters

- **T** [array-like of shape (n_samples,) or (n_samples, 1)] Data to transform.

Returns

- **y_pred** [ndarray of shape (n_samples,)] Transformed data.

`sccore`(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $(y_{true} - y_{pred})^2$.sum() and $v$ is the total sum of squares $(y_{true} - y_{true}.mean())^2$.sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (T)

Transform new data by linear interpolation

Parameters

T [array-like of shape (n_samples,) or (n_samples, 1)] Data to transform.

Changed in version 0.24: Also accepts 2d array with 1 feature.

Returns

y_pred [ndarray of shape (n_samples,)] The transformed data

Examples using sklearn.isotonic.IsotonicRegression

• Isotonic Regression

isotonic.check_increasing(x, y) Determine whether y is monotonically correlated with x.

isotonic.isotonic_regression(y, *[...]) Solve the isotonic regression model.

7.19.2 sklearn.isotonic.check_increasing

sklearn.isotonic.check_increasing(x, y)

Determine whether y is monotonically correlated with x.

y is found increasing or decreasing with respect to x based on a Spearman correlation test.

Parameters

x [array-like of shape (n_samples,)] Training data.

y [array-like of shape (n_samples,)] Training target.

Returns
**increasing_bool** [boolean] Whether the relationship is increasing or decreasing.

**Notes**

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.

### 7.19.3 sklearn.isotonic.isotonic_regression

```python
sklearn.isotonic.isotonic_regression(y, *, sample_weight=None, y_min=None, y_max=None, increasing=True)
```

Solve the isotonic regression model.

Read more in the *User Guide*.

**Parameters**

- `y` [array-like of shape (n_samples,)] The data.
- `sample_weight` [array-like of shape (n_samples,), default=None] Weights on each point of the regression. If None, weight is set to 1 (equal weights).
- `y_min` [float, default=None] Lower bound on the lowest predicted value (the minimum value may still be higher). If not set, defaults to -inf.
- `y_max` [float, default=None] Upper bound on the highest predicted value (the maximum may still be lower). If not set, defaults to +inf.
- `increasing` [bool, default=True] Whether to compute `y` is increasing (if set to True) or decreasing (if set to False)

**Returns**

- `y` [list of floats] Isotonic fit of `y`.

7.20.1 sklearn.kernel_approximation.AdditiveChi2Sampler

```python
class sklearn.kernel_approximation.AdditiveChi2Sampler(**kwargs)
```

Approximate feature map for additive chi2 kernel.

Uses sampling the fourier transform of the kernel characteristic at regular intervals.

Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into 2*sample_steps+1 features, where sample_steps is a parameter of the method. Typical values of sample_steps include 1, 2 and 3.

Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable.

Read more in the User Guide.

**Parameters**

- `sample_steps` [int, default=2] Gives the number of (complex) sampling points.
- `sample_interval` [float, default=None] Sampling interval. Must be specified when sample_steps not in {1,2,3}.

**Attributes**

- `sample_interval_` [float] Stored sampling interval. Specified as a parameter if sample_steps not in {1,2,3}.

See also:

- `SkewedChi2Sampler` A Fourier-approximation to a non-additive variant of the chi squared kernel.
- `sklearn.metrics.pairwise.chi2_kernel` The exact chi squared kernel.
- `sklearn.metrics.pairwise.additive_chi2_kernel` The exact additive chi squared kernel.
Notes

This estimator approximates a slightly different version of the additive chi squared kernel than metric.additive_chi2 computes.

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.kernel_approximation import AdditiveChi2Sampler

>>> X, y = load_digits(return_X_y=True)
>>> chi2sampler = AdditiveChi2Sampler(sample_steps=2)
>>> X_transformed = chi2sampler.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=5, random_state=0, tol=1e-3)
>>> clf.fit(X_transformed, y)
SGDClassifier(max_iter=5, random_state=0)
>>> clf.score(X_transformed, y)
0.9499...
```

Methods

- `fit(X[, y])` Set the parameters
- `fit_transform(X[, y])` Fit to data, then transform it.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Apply approximate feature map to X.

**fit** (X, y=None)

Set the parameters

Parameters

- `X` [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

- `self` [object] Returns the transformer.

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` [array-like of shape (n_samples, n_features)] Input samples.
**y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

**X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

**self** [estimator instance] Estimator instance.

**transform**(X)
Apply approximate feature map to X.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)]

**Returns**

**X_new** [{ndarray, sparse matrix}, shape = (n_samples, n_features * (2*sample_steps + 1))] Whether the return value is an array of sparse matrix depends on the type of the input X.

### 7.20.2 sklearn.kernel_approximation.Nystroem

**class** sklearn.kernel_approximation.Nystroem(**kwargs**)  
Approximate a kernel map using a subset of the training data.

Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the *User Guide*.

New in version 0.13.

**Parameters**

**kernel** [string or callable, default=’rbf’] Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.
gamma  [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

coeff0  [float, default=None] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

degree  [float, default=None] Degree of the polynomial kernel. Ignored by other kernels.

kernel_params  [dict, default=None] Additional parameters (keyword arguments) for kernel function passed as callable object.

n_components  [int, default=100] Number of features to construct. How many data points will be used to construct the mapping.

random_state  [int, RandomState instance or None, default=None] Pseudo-random number generator to control the uniform sampling without replacement of n_components of the training data to construct the basis kernel. Pass an int for reproducible output across multiple function calls. See Glossary.

n_jobs  [int, default=None] The number of jobs to use for the computation. This works by breaking down the kernel matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.24.

Attributes

components_  [ndarray of shape (n_components, n_features)] Subset of training points used to construct the feature map.

component_indices_  [ndarray of shape (n_components)] Indices of components_ in the training set.

normalization_  [ndarray of shape (n_components, n_components)] Normalization matrix needed for embedding. Square root of the kernel matrix on components_.

See also:

RBFSampler  An approximation to the RBF kernel using random Fourier features.

sklearn.metrics.pairwise.kernel_metrics  List of built-in kernels.

Examples

```python
>>> from sklearn import datasets, svm
>>> from sklearn.kernel_approximation import Nystroem

>>> X, y = datasets.load_digits(n_class=9, return_X_y=True)

>>> data = X / 16.

>>> clf = svm.LinearSVC()

>>> feature_map_nystroem = Nystroem(gamma=.2,
...                                 random_state=1,
...                                 n_components=300)

>>> data_transformed = feature_map_nystroem.fit_transform(data)

>>> clf.fit(data_transformed, y)

>>> clf.score(data_transformed, y)

0.9987...
```

Methods

---

**fit** *(X[, y])*

Fit estimator to data.

Samples a subset of training points, computes kernel on these and computes normalization matrix.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))*
  Training data.

**fit_transform** *(X[, y][, fit_params]*)

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))*
  Input samples.
- **y** *(array-like of shape (n_samples), or (n_samples, n_outputs), default=None)*
  Target values (None for unsupervised transformations).
- **fit_params** *(dict)*
  Additional fit parameters.

**Returns**

- **X_new** *(ndarray array of shape (n_samples, n_features_new))*
  Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** *(bool, default=True)*
  If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

(params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

(**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Apply feature map to X.

Computes an approximate feature map using the kernel between some training points and X.

Parameters

X [array-like of shape (n_samples, n_features)] Data to transform.

Returns

X_transformed [ndarray of shape (n_samples, n_components)] Transformed data.

Examples using sklearn.kernel_approximation.Nystroem

• Explicit feature map approximation for RBF kernels

7.20.3 sklearn.kernel_approximation.PolynomialCountSketch
class sklearn.kernel_approximation.PolynomialCountSketch(*, gamma=1.0, degree=2, coef0=0, n_components=100, random_state=None)
Polynomial kernel approximation via Tensor Sketch.

Implements Tensor Sketch, which approximates the feature map of the polynomial kernel:

\[ K(X, Y) = (\gamma \cdot \langle X, Y \rangle + \text{coef0})^\text{degree} \]

by efficiently computing a Count Sketch of the outer product of a vector with itself using Fast Fourier Transforms (FFT). Read more in the User Guide.

New in version 0.24.

Parameters

gamma [float, default=1.0] Parameter of the polynomial kernel whose feature map will be approximated.

degree [int, default=2] Degree of the polynomial kernel whose feature map will be approximated.
coef0 [int, default=0] Constant term of the polynomial kernel whose feature map will be approximated.

n_components [int, default=100] Dimensionality of the output feature space. Usually, n_components should be greater than the number of features in input samples in order to achieve good performance. The optimal score / run time balance is typically achieved around n_components = 10 * n_features, but this depends on the specific dataset being used.

random_state [int, RandomState instance, default=None] Determines random number generation for indexHash and bitHash initialization. Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes

indexHash_ [ndarray of shape (degree, n_features), dtype=int64] Array of indexes in range [0, n_components) used to represent the 2-wise independent hash functions for Count Sketch computation.

bitHash_ [ndarray of shape (degree, n_features), dtype=float32] Array with random entries in {+1, -1}, used to represent the 2-wise independent hash functions for Count Sketch computation.

Examples

```python
>>> from sklearn.kernel_approximation import PolynomialCountSketch
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> ps = PolynomialCountSketch(degree=3, random_state=1)
>>> X_features = ps.fit_transform(X)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=10)
>>> clf.score(X_features, y)
1.0
```

Methods

- **fit(X, y=None)** Fit the model with X.
- **fit_transform(X, y=None)** Fit to data, then transform it.
- **get_params(deep=True)** Get parameters for this estimator.
- **set_params(**params)** Set the parameters of this estimator.
- **transform(X)** Generate the feature map approximation for X.

**fit (X, y=None)**

Fit the model with X.

Initializes the internal variables. The method needs no information about the distribution of data, so we only care about n_features in X.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.
Returns

self [object] Returns the transformer.

**fit_transform** *(X, y=None, **fit_params)*
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**set_params** (**params**)
Set the parameters of this estimator.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

**transform** *(X)*
Generate the feature map approximation for X.

Parameters

X [(array-like), shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]
Examples using `sklearn.kernel_approximation.PolynomialCountSketch`  

• Scalable learning with polynomial kernel approximation

7.20.4 `sklearn.kernel_approximation.RBFSampler`  

**class** `sklearn.kernel_approximation.RBFSampler(**kwargs)`  

Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.

It implements a variant of Random Kitchen Sinks.[1]

Read more in the User Guide.

**Parameters**

- `gamma` [float, default=1.0] Parameter of RBF kernel: \(\exp(-\gamma x^2)\)
- `n_components` [int, default=100] Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.
- `random_state` [int, `RandomState` instance or None, default=None] Pseudo-random number generator to control the generation of the random weights and random offset when fitting the training data. Pass an int for reproducible output across multiple function calls. See Glossary.

**Attributes**

- `random_offset_` [ndarray of shape (n_components,), dtype=float64] Random offset used to compute the projection in the n_components dimensions of the feature space.
- `random_weights_` [ndarray of shape (n_features, n_components), dtype=float64] Random projection directions drawn from the Fourier transform of the RBF kernel.

**Notes**

See “Random Features for Large-Scale Kernel Machines” by A. Rahimi and Benjamin Recht.

**Examples**

```python
>>> from sklearn.kernel_approximation import RBFSampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> rbf_feature = RBFSampler(gamma=1, random_state=1)
>>> X_features = rbf_feature.fit_transform(X)
>>> clf = SGDClassifier(max_iter=5, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=5)
>>> clf.score(X_features, y)
1.0
```

**fit** *(X, y=None)*  
Fit the model with X.

Samples random projection according to n_features.

**Parameters**

- X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**Returns**

self [object] Returns the transformer.

**fit_transform** *(X, y=None, **fit_params)*  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Input samples.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*

Returns

self [estimator instance] Estimator instance.

transform(X)
Apply the approximate feature map to X.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples using sklearn.kernel_approximation.RBFSampler

- Explicit feature map approximation for RBF kernels

7.20.5 sklearn.kernel_approximation.SkewedChi2Sampler

class sklearn.kernel_approximation.SkewedChi2Sampler(**kwargs)
Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.

Read more in the User Guide.

Parameters

skewedness [float, default=1.0] “skewedness” parameter of the kernel. Needs to be cross-validated.

n_components [int, default=100] number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state [int, RandomState instance or None, default=None] Pseudo-random number generator to control the generation of the random weights and random offset when fitting the training data. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

random_weights_ [ndarray of shape (n_features, n_components)] Weight array, sampled from a secant hyperbolic distribution, which will be used to linearly transform the log of the data.

random_offset_ [ndarray of shape (n_features, n_components)] Bias term, which will be added to the data. It is uniformly distributed between 0 and 2*pi.

See also:

AdditiveChi2Sampler A different approach for approximating an additive variant of the chi squared kernel.

sklearn.metrics.pairwise.chi2_kernel The exact chi squared kernel.
References

See “Random Fourier Approximations for Skewed Multiplicative Histogram Kernels” by Fuxin Li, Catalin Ionescu and Cristian Sminchisescu.

Examples

```python
>>> from sklearn.kernel_approximation import SkewedChi2Sampler
>>> from sklearn.linear_model import SGDClassifier

>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> chi2_feature = SkewedChi2Sampler(skewedness=.01,
...                                   n_components=10,
...                                   random_state=0)
>>> X_features = chi2_feature.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=10)
>>> clf.score(X_features, y)
1.0
```

**fit**

(X, y=None)

Fit the model with X.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the transformer.

**fit_transform**

(X, y=None, **fit_params)

Fit to data, then transform it.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.
Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form "<component>__<parameter>" so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Apply the approximate feature map to X.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples in the number of
samples and n_features is the number of features. All values of X must be strictly greater
than “skewedness”.

Returns

X_new [array-like, shape (n_samples, n_components)]

7.21 sklearn.kernel_ridge: Kernel Ridge Regression

Module sklearn.kernel_ridge implements kernel ridge regression.

User guide: See the Kernel ridge regression section for further details.

7.21.1 `sklearn.kernel_ridge.KernelRidge`

```python
class sklearn.kernel_ridge.KernelRidge(**kwargs)
```

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for epsilon > 0, at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the *User Guide*.

**Parameters**

- **alpha**: [float or array-like of shape (n_targets,), default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to \( \frac{1}{2C} \) in other linear models such as *LogisticRegression* or *LinearSVC*. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number. See *Ridge regression and classification* for formula.

- **kernel**: [string or callable, default="linear"] Kernel mapping used internally. This parameter is directly passed to `pairwise.kernel`. If `kernel` is a string, it must be one of the metrics in `pairwise.PAIRWISE_KERNEL_FUNCTIONS`. If `kernel` is “precomputed”, `X` is assumed to be a kernel matrix. Alternatively, if `kernel` is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two rows from `X` as input and return the corresponding kernel value as a single number. This means that callables from *sklearn.metrics.pairwise* are not allowed, as they operate on matrices, not single samples. Use the string identifying the kernel instead.

- **gamma**: [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for *sklearn.metrics.pairwise*. Ignored by other kernels.

- **degree**: [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

- **coef0**: [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

- **kernel_params**: [mapping of string to any, default=None] Additional parameters (keyword arguments) for kernel function passed as callable object.

**Attributes**

- **dual_coef_**: [ndarray of shape (n_samples,) or (n_samples, n_targets)] Representation of weight vector(s) in kernel space

- **X_fit_**: [[ndarray, sparse matrix] of shape (n_samples, n_features)] Training data, which is also required for prediction. If `kernel == “precomputed”` this is instead the precomputed training matrix, of shape (n_samples, n_samples).

See also:
**sklearn.linear_model.Ridge**  Linear ridge regression.

**sklearn.svm.SVR**  Support Vector Regression implemented using libsvm.

**References**

**Examples**

```python
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0)
```

**Methods**

- `fit(X, y[, sample_weight])`  Fit Kernel Ridge regression model
- `get_params([deep])`  Get parameters for this estimator.
- `predict(X)`  Predict using the kernel ridge model
- `score(X, y[, sample_weight])`  Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)`  Set the parameters of this estimator.

**fit**  
Fit Kernel Ridge regression model

**Parameters**

- `X`  [array-like, sparse matrix] of shape (n_samples, n_features)  Training data. If kernel == “precomputed” this is instead a precomputed kernel matrix, of shape (n_samples, n_samples).
- `y`  [array-like of shape (n_samples,) or (n_samples, n_targets)]  Target values
- `sample_weight`  [float or array-like of shape (n_samples,), default=None]  Individual weights for each sample, ignored if None is passed.

**Returns**

- `self`  [returns an instance of self.]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- `deep`  [bool, default=True]  If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params** [dict] Parameter names mapped to their values.

**predict**(X)

Predict using the kernel ridge model

Parameters

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples. If kernel == “precomputed” this is instead a precomputed kernel matrix, shape = [n_samples, n_samples_fitted], where n_samples_fitted is the number of samples used in the fitting for this estimator.

Returns

**C** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Returns predicted values.

**score**(X, y, **sample_weight=None**)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

**self** [estimator instance] Estimator instance.
7.22 sklearn.linear_model: Linear Models

The `sklearn.linear_model` module implements a variety of linear models.

**User guide:** See the Linear Models section for further details.

The following subsections are only rough guidelines: the same estimator can fall into multiple categories, depending on its parameters.

### 7.22.1 Linear classifiers

- **linear_model.LogisticRegression(**kwargs)** Logistic Regression (aka logit, MaxEnt) classifier.
- **linear_model.LogisticRegressionCV(**kwargs)** Logistic Regression CV (aka logit, MaxEnt) classifier.
- **linear_model.Perceptron(**kwargs)** Read more in the User Guide.
- **linear_model.RidgeClassifier(**kwargs)** Classifier using Ridge regression.
- **linear_model.RidgeClassifierCV(**kwargs)** Ridge classifier with built-in cross-validation.
- **linear_model.SGDClassifier(**kwargs)** Linear classifiers (SVM, logistic regression, etc.) with SGD training.

**sklearn.linear_model.LogisticRegression**

**class sklearn.linear_model.LogisticRegression(**kwargs)** Logistic Regression (aka logit, MaxEnt) classifier.

In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the `multi_class` option is set to ‘ovr’, and uses the cross-entropy loss if the `multi_class` option is set to ‘multinomial’. (Currently the ‘multinomial’ option is supported only by the ‘lbfgs’, ‘sag’ and ‘newton-cg’ solvers.)

This class implements regularized logistic regression using the ‘liblinear’ library, ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ solvers. **Note that regularization is applied by default.** It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The ‘newton-cg’, ‘sag’, and ‘lbfgs’ solvers support only L2 regularization with primal formulation, or no regularization. The ‘liblinear’ solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty. The Elastic-Net regularization is only supported by the ‘saga’ solver.

Read more in the User Guide.

**Parameters**

- **penalty** ([‘l1’, ‘l2’, ‘elasticnet’, ‘none’], default=’l2’) Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only L2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver. If ‘none’ (not supported by the liblinear solver), no regularization is applied.

New in version 0.19: 11 penalty with SAGA solver (allowing ‘multinomial’ + L1)
dual [bool, default=False] Dual or primal formulation. Dual formulation is only implemented for L2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

tol [float, default=1e-4] Tolerance for stopping criteria.

C [float, default=1.0] Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

fit_intercept [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

intercept_scaling [float, default=1] Useful only when the solver ‘liblinear’ is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

Note! the synthetic feature weight is subject to 11/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

class_weight [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

New in version 0.17: class_weight=’balanced’

random_state [int, RandomState instance, default=None] Used when solver == ‘sag’, ‘saga’ or ‘liblinear’ to shuffle the data. See Glossary for details.

• For small datasets, ‘liblinear’ is a good choice, whereas ‘sag’ and ‘saga’ are faster for large ones.

• For multiclass problems, only ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ handle multinomial loss; ‘liblinear’ is limited to one-versus-rest schemes.

• ‘newton-cg’, ‘lbfgs’, ‘sag’ and ‘saga’ handle L2 or no penalty

• ‘liblinear’ and ‘saga’ also handle L1 penalty

• ‘saga’ also supports ‘elasticnet’ penalty

• ‘liblinear’ does not support setting penalty=’none’

Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

Changed in version 0.22: The default solver changed from ‘liblinear’ to ‘lbfgs’ in 0.22.

max_iter [int, default=100] Maximum number of iterations taken for the solvers to converge.
**multi_class** ([{'auto', 'ovr', 'multinomial'}, default='auto']) If the option chosen is ‘ovr’, then a binary problem is fit for each label. For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution, even when the data is binary. ‘multinomial’ is unavailable when solver='liblinear'. ‘auto’ selects ‘ovr’ if the data is binary, or if solver='liblinear', and otherwise selects ‘multinomial’.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.

Changed in version 0.22: Default changed from ‘ovr’ to ‘auto’ in 0.22.

**verbose** [int, default=0] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver. See the Glossary.

New in version 0.17: warm_start to support lbfgs, newton-cg, sag, saga solvers.

**n_jobs** [int, default=None] Number of CPU cores used when parallelizing over classes if multi_class='ovr’”. This parameter is ignored when the solver is set to ‘liblinear’ regardless of whether ‘multi_class’ is specified or not. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**l1_ratio** [float, default=None] The Elastic-Net mixing parameter, with 0 <= l1_ratio <= 1. Only used if penalty='elasticnet'. Setting l1_ratio=0 is equivalent to using penalty='l2', while setting l1_ratio=1 is equivalent to using penalty='l1'. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

Attributes

**classes_** [ndarray of shape (n_classes,)] A list of class labels known to the classifier.

**coef_** [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

  - coef_ is of shape (1, n_features) when the given problem is binary. In particular, when multi_class='multinomial', coef_ corresponds to outcome 1 (True) and -coef_ corresponds to outcome 0 (False).

**intercept_** [ndarray of shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision function.

  - If fit_intercept is set to False, the intercept is set to zero. intercept_ is of shape (1,) when the given problem is binary. In particular, when multi_class='multinomial', intercept_ corresponds to outcome 1 (True) and -intercept_ corresponds to outcome 0 (False).

**n_iter_** [ndarray of shape (n_classes,) or (1,)] Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.

Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed max_iter. n_iter_ will now report at most max_iter.

See also:

**SGDClassifier** Incrementally trained logistic regression (when given the parameter loss="log").

**LogisticRegressionCV** Logistic regression with built-in cross validation.
Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

**decision_function** (*X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify**()
Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

self Fitted estimator.

**fit** (*X, y, sample_weight=None*)
Fit the model according to the given training data.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target vector relative to X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: sample_weight support to LogisticRegression.

**Returns**

self Fitted estimator.

**Notes**

The SAGA solver supports both float64 and float32 bit arrays.

**get_params** (deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**predict** (*X*)
Predict class labels for samples in X.

**Parameters**
**X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

**C** [array, shape [n_samples]] Predicted class label per sample.

**predict_log_proba** *(X)*

Predict logarithm of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

**T** [array-like of shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**predict_proba** *(X)*

Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function. and normalize these values across all the classes.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

**T** [array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**
**params**  [dict] Estimator parameters.

**Returns**

self  [estimator instance] Estimator instance.

sparsify()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

**Returns**

self  Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

**sklearn.linear_model.LogisticRegressionCV**

class sklearn.linear_model.LogisticRegressionCV(**kwargs)

Logistic Regression CV (aka logit, MaxEnt) classifier.

See glossary entry for cross-validation estimator.

This class implements logistic regression using liblinear, newton-cg, sag or lbfgs optimizer. The newton-cg, sag and lbfgs solvers support only L2 regularization with primal formulation. The liblinear solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty. Elastic-Net penalty is only supported by the saga solver.

For the grid of Cs values and l1_ratios values, the best hyperparameter is selected by the cross-validator StratifiedKFold, but it can be changed using the cv parameter. The ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ solvers can warm-start the coefficients (see Glossary).

Read more in the User Guide.

**Parameters**

- **Cs** [int or list of floats, default=10] Each of the values in Cs describes the inverse of regularization strength. If Cs is an int, then a grid of Cs values are chosen in a logarithmic scale between 1e-4 and 1e4. Like in support vector machines, smaller values specify stronger regularization.

- **fit_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

- **cv** [int or cross-validation generator, default=None] The default cross-validation generator used is Stratified K-Folds. If an integer is provided, then it is the number of folds used. See the module sklearn.model_selection module for the list of possible cross-validation objects.

  Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **dual** [bool, default=False] Dual or primal formulation. Dual formulation is only implemented for L2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

- **penalty** [‘l1’, ‘l2’, ‘elasticnet’], default=’l2’ Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only L2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver.

- **scoring** [str or callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y). For a list of scoring functions that can be used, look at sklearn.metrics. The default scoring option used is ‘accuracy’.

  - For small datasets, ‘liblinear’ is a good choice, whereas ‘sag’ and ‘saga’ are faster for large ones.
For multiclass problems, only 'newton-cg', 'sag', 'saga' and 'lbfgs' handle multinomial loss; 'liblinear' is limited to one-versus-rest schemes.

- 'newton-cg', 'lbfgs' and 'sag' only handle L2 penalty, whereas 'liblinear' and 'saga' handle L1 penalty.
- 'liblinear' might be slower in LogisticRegressionCV because it does not handle warm-starting.

Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

tol [float, default=1e-4] Tolerance for stopping criteria.

max_iter [int, default=100] Maximum number of iterations of the optimization algorithm.

class_weight [dict or 'balanced', default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

New in version 0.17: class_weight == ‘balanced’

n_jobs [int, default=None] Number of CPU cores used during the cross-validation loop. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int, default=0] For the 'liblinear', 'sag' and 'lbfgs' solvers set verbose to any positive number for verbosity.

refit [bool, default=True] If set to True, the scores are averaged across all folds, and the coefs and the C that corresponds to the best score is taken, and a final refit is done using these parameters. Otherwise the coefs, intercepts and C that correspond to the best scores across folds are averaged.

intercept_scaling [float, default=1] Useful only when the solver 'liblinear' is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

Note! the synthetic feature weight is subject to 11/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

multi_class [['auto', 'ovr', 'multinomial'], default='auto'] If the option chosen is 'ovr', then a binary problem is fit for each label. For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution, even when the data is binary. ‘multinomial’ is unavailable when solver='liblinear'. ‘auto’ selects ‘ovr’ if the data is binary, or if solver='liblinear', and otherwise selects ‘multinomial’.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.

Changed in version 0.22: Default changed from ‘ovr’ to ‘auto’ in 0.22.
random_state [int, RandomState instance, default=None] Used when solver='sag', 'saga' or 'liblinear' to shuffle the data. Note that this only applies to the solver and not the cross-validation generator. See Glossary for details.

l1_ratios [list of float, default=None] The list of Elastic-Net mixing parameter, with 0 <= l1_ratio <= 1. Only used if penalty='elasticnet'. A value of 0 is equivalent to using penalty='l2', while 1 is equivalent to using penalty='l1'. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

Attributes

classes_ [ndarray of shape (n_classes,)] A list of class labels known to the classifier.

coeff_ [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

coeff_ is of shape (1, n_features) when the given problem is binary.

intercept_ [ndarray of shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision function.

If fit_intercept is set to False, the intercept is set to zero. intercept_ is of shape(1,) when the problem is binary.

Cs_ [ndarray of shape (n_cs)] Array of C i.e. inverse of regularization parameter values used for cross-validation.

l1_ratios_ [ndarray of shape (n_l1_ratios)] Array of l1_ratios used for cross-validation. If no l1_ratio is used (i.e. penalty is not 'elasticnet'), this is set to [None]

coeffs_paths_ [ndarray of shape (n_folds, n_cs, n_features) or (n_folds, n_cs, n_features + 1)] dict with classes as the keys, and the path of coefficients obtained during cross-validating across each fold and then across each Cs after doing an OvR for the corresponding class as values. If the ‘multi_class’ option is set to ‘multinomial’, then the coeff_paths are the coefficients corresponding to each class. Each dict value has shape (n_folds, n_cs, n_features) or (n_folds, n_cs, n_features + 1) depending on whether the intercept is fit or not. If penalty='elasticnet', the shape is (n_folds, n_cs, n_l1_ratios_, n_features) or (n_folds, n_cs, n_l1_ratios_, n_features + 1).

scores_ [dict] dict with classes as the keys, and the values as the grid of scores obtained during cross-validating each fold, after doing an OvR for the corresponding class. If the ‘multi_class’ option given is ‘multinomial’ then the same scores are repeated across all classes, since this is the multinomial class. Each dict value has shape (n_folds, n_cs) or (n_folds, n_cs, n_l1_ratios) if penalty='elasticnet'.

C_ [ndarray of shape (n_classes,) or (n_classes - 1,)] Array of C that maps to the best scores across every class. If refit is set to False, then for each class, the best C is the average of the C’s that correspond to the best scores for each fold. C_ is of shape(n_classes,) when the problem is binary.

l1_ratios_ [ndarray of shape (n_l1_ratios) or (n_l1_ratios - 1,)] Array of l1_ratio that maps to the best scores across every class. If refit is set to False, then for each class, the best l1_ratio is the average of the l1_ratio’s that correspond to the best scores for each fold. l1_ratio_ is of shape(n_classes,) when the problem is binary.

n_iter_ [ndarray of shape (n_classes, n_folds, n_cs) or (1, n_folds, n_cs)] Actual number of iterations for all classes, folds and Cs. In the binary or multinomial cases, the first dimension is equal to 1. If penalty='elasticnet', the shape is (n_classes, n_folds, n_cs, n_l1_ratios) or (1, n_folds, n_cs, n_l1_ratios).

### Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegressionCV
>>> X, y = load_iris(return_X_y=True)
>>> clf = LogisticRegressionCV(cv=5, random_state=0).fit(X, y)
>>> clf.predict(X[:2, :])
array([0, 0])
>>> clf.predict_proba(X[:2, :]).shape
(2, 3)
>>> clf.score(X, y)
0.98...
```

### Methods

- **decision_function(X)** Predict confidence scores for samples.
- **densify()** Convert coefficient matrix to dense array format.
- **fit(X, y[, sample_weight])** Fit the model according to the given training data.
- **get_params([deep])** Get parameters for this estimator.
- **predict(X)** Predict class labels for samples in X.
- **predict_log_proba(X)** Predict logarithm of probability estimates.
- **predict_proba(X)** Probability estimates.
- **score(X, y[, sample_weight])** Returns the score using the scoring option on the given test data and labels.
- **set_params(**params)** Set the parameters of this estimator.
- **sparsify()** Convert coefficient matrix to sparse format.

**decision_function(X)**

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **array**, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify()**

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- **self** Fitted estimator.
**fit** *(X, y, sample_weight=None)*

Fit the model according to the given training data.

**Parameters**

- **X**  
  [array-like, sparse matrix] of shape (n_samples, n_features) 
  Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y**  
  [array-like of shape (n_samples,)] 
  Target vector relative to X.

- **sample_weight**  
  [array-like of shape (n_samples,), default=None] 
  Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**Returns**

- **self**  
  [object]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep**  
  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**  
  [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

- **X**  
  [array-like or sparse matrix, shape (n_samples, n_features)] 
  Samples.

**Returns**

- **C**  
  [array, shape [n_samples]] 
  Predicted class label per sample.

**predict_log_proba** *(X)*

Predict logarithm of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

**Parameters**

- **X**  
  [array-like of shape (n_samples, n_features)] 
  Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **T**  
  [array-like of shape (n_samples, n_classes)] 
  Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

**predict_proba** *(X)*

Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function, and normalize these values across all the classes.

**Parameters**
**X** [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

Returns

**T** [array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

**score**(X, y, sample_weight=None)

Returns the score using the scoring option on the given test data and labels.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] Score of self.predict(X) wrt. y.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- ****params** [dict] Estimator parameters.

Returns

- **self** [estimator instance] Estimator instance.

**sparsify**()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

- **self** Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.
sklearn.linear_model.PassiveAggressiveClassifier

class sklearn.linear_model.PassiveAggressiveClassifier(**kwargs)

Passive Aggressive Classifier

Read more in the User Guide.

Parameters

C [float, default=1.0] Maximum step size (regularization). Defaults to 1.0.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

New in version 0.19.

tol [float or None, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

New in version 0.19.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [integer, default=0] The verbosity level

loss [string, default="hinge"] The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared_hinge: equivalent to PA-II in the reference paper.

n_jobs [int or None, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance, default=None] Used to shuffle the training data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.
**class_weight** [dict, {class_label: weight} or “balanced” or None, default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as \( \frac{n_{samples}}{n_{classes} \times np.bincount(y)} \)

New in version 0.17: parameter *class_weight* to automatically weight samples.

**average** [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

**Attributes**

- `coef_` [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

- `intercept_` [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

- `n_iter_` [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

- `classes_` [array of shape (n_classes,)] The unique classes labels.

- `t_` [int] Number of weight updates performed during training. Same as \((n_{iter} \times n_{samples})\).

- `loss_function_` [callable] Loss function used by the algorithm.

**Examples**

```python
>>> from sklearn.linear_model import PassiveAggressiveClassifier
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_features=4, random_state=0)
>>> clf = PassiveAggressiveClassifier(max_iter=1000, random_state=0,
... tol=1e-3)
>>> clf.fit(X, y)
PassiveAggressiveClassifier(random_state=0)
>>> print(clf.coef_)
[[0.26642044 0.45070924 0.67251877 0.64185414]]
>>> print(clf.intercept_)
```

(continues on next page)
```python
>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

## Methods

### decision_function(X)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X**: [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **array**, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes): Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

### densify()
Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- **self**: Fitted estimator.

### fit(X, y, coef_init=None, intercept_init=None)
Fit linear model with Passive Aggressive algorithm.

**Parameters**

- **X**: [array-like, sparse matrix] of shape (n_samples, n_features) Training data
- **y**: [numpy array] of shape [n_samples] Target values
- **coef_init**: [array, shape = [n_classes, n_features]] The initial coefficients to warm-start the optimization.
- **intercept_init**: [array, shape = [n_classes]] The initial intercept to warm-start the optimization.
Returns

self [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

partial_fit (X, y, classes=None)
Fit linear model with Passive Aggressive algorithm.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Subset of the training data
y [ndarray of shape [n_samples]] Subset of the target values
classes [array, shape = [n_classes]] Classes across all calls to partial_fit. Can be obtained
by via np.unique(y_all), where y_all is the target vector of the entire dataset. This
argument is required for the first call to partial_fit and can be omitted in the subsequent
calls. Note that y doesn’t need to contain all labels in classes.

Returns

self [returns an instance of self.]

predict (X)
Predict class labels for samples in X.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**kwargs)
Set and validate the parameters of estimator.

Parameters
**kwargs [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with \((coef_ == 0).sum()\), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.PassiveAggressiveClassifier

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

sklearn.linear_model.Perceptron

class sklearn.linear_model.Perceptron(**kwargs)

Read more in the User Guide.

Parameters

penalty [‘l2’, ‘l1’, ‘elasticnet’], default=None] The penalty (aka regularization term) to be used.

alpha [float, default=0.0001] Constant that multiplies the regularization term if regularization is used.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

New in version 0.19.

tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when 

\((loss > previous_loss - tol)\).

New in version 0.19.
shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level

eta0 [double, default=1] Constant by which the updates are multiplied.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance, default=None] Used to shuffle the training data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

class_weight [dict, {class_label: weight} or “balanced”, default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Attributes

classes_ [ndarray of shape (n_classes,)] The unique classes labels.

coeff_ [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features.

intercept_ [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

loss_function_ [concrete LossFunction] The function that determines the loss, or difference between the output of the algorithm and the target values.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

t_ [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

See also:
**SGDClassifier**

**Notes**

Perceptron is a classification algorithm which shares the same underlying implementation with SGDClassifier. In fact, Perceptron() is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

**References**

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import Perceptron
>>> X, y = load_digits(return_X_y=True)
>>> clf = Perceptron(tol=1e-3, random_state=0)
>>> clf.fit(X, y)
Perceptron()
>>> clf.score(X, y)
0.939...
```

**Methods**

- `decision_function(X)` Predict confidence scores for samples.
- `densify()` Convert coefficient matrix to dense array format.
- `fit(X, y[, coef_init, intercept_init, ...])` Fit linear model with Stochastic Gradient Descent.
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, classes, sample_weight])` Perform one epoch of stochastic gradient descent on given samples.
- `predict(X)` Predict class labels for samples in X.
- `score(X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(**kwargs)` Set and validate the parameters of estimator.
- `sparsify()` Convert coefficient matrix to sparse format.

**decision_function** *(X)*

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.
densify()
Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns
self  Fitted estimator.

fit(X, y, coef_init=None, intercept_init=None, sample_weight=None)
Fit linear model with Stochastic Gradient Descent.

Parameters
X  [array-like, sparse matrix], shape (n_samples, n_features) Training data.
y  [ndarray of shape (n_samples,)] Target values.
coef_init  [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.
intercept_init  [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.
sample_weight  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns
self : Returns an instance of self.

get_params(deep=True)
Get parameters for this estimator.

Parameters
deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params  [dict] Parameter names mapped to their values.

partial_fit(X, y, classes=None, sample_weight=None)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters
X  [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of the training data.
y  [ndarray of shape (n_samples,)] Subset of the target values.
classes  [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.
sample_weight  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.
Returns

    self : Returns an instance of self.

**predict**(X)

Predict class labels for samples in X.

**Parameters**

    X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

    C [array, shape [n_samples]] Predicted class label per sample.

**score**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

    X [array-like of shape (n_samples, n_features)] Test samples.
    y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
    sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

    score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(**kwargs)

Set and validate the parameters of estimator.

**Parameters**

    **kwargs [dict] Estimator parameters.

**Returns**

    self [object] Estimator instance.

**sparsify**()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

**Returns**

    self Fitted estimator.
Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.Perceptron

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

sklearn.linear_model.RidgeClassifier

class sklearn.linear_model.RidgeClassifier(**kwargs)

Classifier using Ridge regression.

This classifier first converts the target values into {-1, 1} and then treats the problem as a regression task (multi-output regression in the multiclass case).

Read more in the User Guide.

Parameters

- **alpha** [float, default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to 1 / (2C) in other linear models such as LogisticRegression or LinearSVC.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

- **max_iter** [int, default=None] Maximum number of iterations for conjugate gradient solver. The default value is determined by scipy.sparse.linalg.

- **tol** [float, default=1e-3] Precision of the solution.

- **class_weight** [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

  The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

  - ‘auto’ chooses the solver automatically based on the type of data.
• ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.

• ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.

• ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).

• ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.

• ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance, default=None] Used when solver == ‘sag’ or ‘saga’ to shuffle the data. See Glossary for details.

Attributes

coef_ [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

c coef _ is of shape (1, n_features) when the given problem is binary.

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

n_iter_ [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

classes_ [ndarray of shape (n_classes,)] The classes labels.

See also:

Ridge Ridge regression.

RidgeClassifierCV Ridge classifier with built-in cross validation.

Notes

For multi-class classification, n_class classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.
Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import RidgeClassifier

>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = RidgeClassifier().fit(X, y)
>>> clf.score(X, y)
0.9595...
```

**decision_function(X)**

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- `array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)`
  - Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where >0 means this class would be predicted.

**fit (X, y, sample_weight=None)**

Fit Ridge classifier model.

**Parameters**

- **X** [(ndarray, sparse matrix) of shape (n_samples, n_features)] Training data.
- **y** [(ndarray of shape (n_samples,))] Target values.
- **sample_weight** [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

New in version 0.17: `sample_weight` support to Classifier.

**Returns**

- **self** [object] Instance of the estimator.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params** [dict] Parameter names mapped to their values.

**predict**(*X*)

Predict class labels for samples in `X`.

**Parameters**

`X` [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

`C` [array, shape [n_samples]] Predicted class label per sample.

**score**(*X, y, sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

`X` [array-like of shape (n_samples, n_features)] Test samples.

`y` [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for `X`.

`sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

`score` [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using sklearn.linear_model.RidgeClassifier**

- Classification of text documents using sparse features

**sklearn.linear_model.RidgeClassifierCV**

**class** sklearn.linear_model.RidgeClassifierCV(**kwargs**)

Ridge classifier with built-in cross-validation.

See glossary entry for cross-validation estimator.

By default, it performs Leave-One-Out Cross-Validation. Currently, only the n_features > n_samples case is handled efficiently.

Read more in the User Guide.
Parameters

alphas [ndarray of shape (n_alphas,), default=(0.1, 1.0, 10.0)] Array of alpha values to try. Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to 1 / (2C) in other linear models such as LogisticRegression or LinearSVC.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

scoring [string, callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- None, to use the efficient Leave-One-Out cross-validation
- integer, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.
Refer User Guide for the various cross-validation strategies that can be used here.

class_weight [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

store_cv_values [bool, default=False] Flag indicating if the cross-validation values corresponding to each alpha should be stored in the cv_values_ attribute (see below). This flag is only compatible with cv=None (i.e. using Leave-One-Out Cross-Validation).

Attributes

cv_values_ [ndarray of shape (n_samples, n_targets, n_alphas), optional] Cross-validation values for each alpha (if store_cv_values=True and cv=None). After fit() has been called, this attribute will contain the mean squared errors (by default) or the values of the (loss, score)_func function (if provided in the constructor). This attribute exists only when store_cv_values is True.

coeff_ [ndarray of shape (1, n_features) or (n_targets, n_features)] Coefficient of the features in the decision function.

coef_ is of shape (1, n_features) when the given problem is binary.

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

alpha_ [float] Estimated regularization parameter.

best_score_ [float] Score of base estimator with best alpha.

New in version 0.23.
classes_  [ndarray of shape (n_classes,)] The classes labels.

decision_function(X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

- **X**  [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)  Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit (X, y, sample_weight=None)

Fit Ridge classifier with cv.

Parameters

- **X**  [ndarray of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. When using GCV, will be cast to 7.22. sklearn.linear_model: Linear Models 2157
float64 if necessary.

y [ndarray of shape (n_samples,)] Target values. Will be cast to X’s dtype if necessary.

sample_weight [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict class labels for samples in X.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
sklearn.linear_model.SGDClassifier

class sklearn.linear_model.SGDClassifier(**kwargs)
Linear classifiers (SVM, logistic regression, etc.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the
gradient of the loss is estimated each sample at a time and the model is updated along the way with a de-
creasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning via the
partial_fit method. For best results using the default learning rate schedule, the data should have zero
mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the
features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector
machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector
using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If
the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for
learning sparse models and achieve online feature selection.

Read more in the User Guide.

Parameters

- loss [str, default='hinge'] The loss function to be used. Defaults to ‘hinge’, which gives a linear
SVM.

  The possible options are ‘hinge’, ‘log’, ‘modified_huber’, ‘squared_hinge’, ‘per-
ceptron’, or a regression loss: ‘squared_loss’, ‘huber’, ‘epsilon_insensitive’, or
‘squared_epsilon_insensitive’.

  The ‘log’ loss gives logistic regression, a probabilistic classifier. ‘modified_huber’ is
another smooth loss that brings tolerance to outliers as well as probability estimates.
‘squared_hinge’ is like hinge but is quadratically penalized. ‘perceptron’ is the linear loss
used by the perceptron algorithm. The other losses are designed for regression but can be
useful in classification as well; see SGDRegressor for a description.

  More details about the losses formulas can be found in the User Guide.

- penalty ['l2', 'l1', 'elasticnet'], default='l2'] The penalty (aka regularization term) to be used.
  Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’
might bring sparsity to the model (feature selection) not achievable with ‘l2’.

- alpha [float, default=0.0001] Constant that multiplies the regularization term. The higher the
  value, the stronger the regularization. Also used to compute the learning rate when set to
  learning_rate is set to ‘optimal’.

- l1_ratio [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1.
  l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Only used if penalty is ‘elas-
ticnet’.

- fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False,
  the data is assumed to be already centered.

- max_iter [int, default=1000] The maximum number of passes over the training data (aka
  epochs). It only impacts the behavior in the fit method, and not the partial_fit
  method.

  New in version 0.19.

- tol [float, default=1e-3] The stopping criterion. If it is not None, training will stop when (loss >
  best_loss - tol) for n_iter_no_change consecutive epochs.
New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level.

epsilon [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if loss is ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance, default=None] Used for shuffling the data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

learning_rate [str, default=’optimal’] The learning rate schedule:
   • ‘constant’: $\eta = \eta_0$
   • ‘optimal’: $\eta = \frac{1}{(\alpha \times (t + t0))}$ where $t0$ is chosen by a heuristic proposed by Leon Bottou.
   • ‘invscaling’: $\eta = \frac{\eta_0}{(t \times power_t)}$
   • ‘adaptive’: $\eta = \eta_0$, as long as the training keeps decreasing. Each time $n_{iter\_no\_change}$ consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if early_stopping is True, the current learning rate is divided by 5.

   New in version 0.20: Added ‘adaptive’ option

eta0 [double, default=0.0] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’ schedules. The default value is 0.0 as eta0 is not used by the default schedule ‘optimal’.

power_t [double, default=0.5] The exponent for inverse scaling learning rate [default 0.5].

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score returned by the score method is not improving by at least tol for $n_{iter\_no\_change}$ consecutive epochs.

   New in version 0.20: Added ‘early_stopping’ option

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

   New in version 0.20: Added ‘validation_fraction’ option

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

   New in version 0.20: Added ‘n_iter_no_change’ option

class_weight [dict, {class_label: weight} or “balanced”, default=None] Preset for the class_weight fit parameter.
Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as \( n_{samples} / (n_{classes} \times np.bincount(y)) \).

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling fit resets this counter, while partial_fit will result in increasing the existing counter.

**average** [bool or int, default=False] When set to True, computes the averaged SGD weights across all updates and stores the result in the \( \text{coef}_\) attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches \( \text{average} \). So \( \text{average}=10 \) will begin averaging after seeing 10 samples.

**Attributes**

- **coef_** [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features.
- **intercept_** [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.
- **n_iter_** [int] The actual number of iterations before reaching the stopping criterion. For multi-class fits, it is the maximum over every binary fit.
- **loss_function_** [concrete LossFunction]
- **classes_** [array of shape (n_classes,)]
- **t_** [int] Number of weight updates performed during training. Same as \( (n_{iter} \times n_{samples}) \).

**See also:**

- *sklearn.svm.LinearSVC* Linear support vector classification.
- *Perceptron* Inherits from SGDClassifier. \( \text{Perceptron}() \) is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

**Examples**

```python
>>> import numpy as np
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.pipeline import make_pipeline
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> Y = np.array([1, 1, 2, 2])
>>> # Always scale the input. The most convenient way is to use a pipeline.
>>> clf = make_pipeline(StandardScaler(),
...                     SGDClassifier(max_iter=1000, tol=1e-3))
>>> clf.fit(X, Y)
```
Pipeline(steps=[('standardscaler', StandardScaler()),
    ('sgdclassifier', SGDClassifier())])

>>> print(clf.predict([[-0.8, -1]]))
[1]

Methods

decision_function(X)  Predict confidence scores for samples.
densify()  Convert coefficient matrix to dense array format.
fit(X, y[, coef_init, intercept_init, ...])  Fit linear model with Stochastic Gradient Descent.
get_params([deep])  Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight])  Perform one epoch of stochastic gradient descent on given samples.
predict(X)  Predict class labels for samples in X.
score(X, y[, sample_weight])  Return the mean accuracy on the given test data and labels.
set_params(**kwargs)  Set and validate the parameters of estimator.
sparisify()  Convert coefficient matrix to sparse format.

decision_function(X)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify()
Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self  Fitted estimator.

fit (X, y, coef_init=None, intercept_init=None, sample_weight=None)
Fit linear model with Stochastic Gradient Descent.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training data.
y [ndarray of shape (n_samples,)] Target values.
coef_init [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.
**intercept_init** [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.

**sample_weight** [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

**Returns**

self : Returns an instance of self.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**partial_fit**(X, y, classes=None, sample_weight=None)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

**Parameters**

X [(array-like, sparse matrix), shape (n_samples, n_features)] Subset of the training data.

y [ndarray of shape (n_samples,)] Subset of the target values.

classes [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

**Returns**

self : Returns an instance of self.

**predict**(X)

Predict class labels for samples in X.

**Parameters**

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

C [array, shape [n_samples]] Predicted class label per sample.

**property predict_log_proba**

Log of probability estimates.

This method is only available for log loss and modified Huber loss.

When loss="modified_huber", probability estimates may be hard zeros and ones, so taking the logarithm is not possible.
See `predict_proba` for details.

**Parameters**

- **X** : array-like or sparse matrix of shape (n_samples, n_features)
  - Input data for prediction.

**Returns**

- **T** : array-like of shape (n_samples, n_classes)
  - Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**property predict_proba**

Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for loss="modified_huber" are given by \((\text{clip}(\text{decision_function}(X), -1, 1) + 1) / 2\). For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with `CalibratedClassifierCV` instead.

**Parameters**

- **X** : array-like or sparse matrix, shape (n_samples, n_features)
  - Input data for prediction.

**Returns**

- ndarray of shape (n_samples, n_classes)
  - Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**References**

The justification for the formula in the loss="modified_huber" case is in the appendix B in: http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf

**score** (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** : array-like of shape (n_samples, n_features)
  - Test samples.

- **y** : array-like of shape (n_samples,) or (n_samples, n_outputs)
  - True labels for X.

- **sample_weight** : array-like of shape (n_samples,), default=None
  - Sample weights.

**Returns**

- **score** : float
  - Mean accuracy of `self.predict(X)` wrt. y.

**set_params** (**kwargs**)

Set and validate the parameters of estimator.

**Parameters**

- **kwargs** : dict
  - Estimator parameters.
**self** [object] Estimator instance.

**sparsify()**
Convert coefficient matrix to sparse format.

Converts the **coef_** member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The **intercept_** member is not converted.

**Returns**

**self** Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in **coef_**, this may actually **increase** memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with 

\[(\text{coef}_ \approx 0).\text{sum}()\]

must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

**Examples using sklearn.linear_model.SGDClassifier**

- Sample pipeline for text feature extraction and evaluation

### 7.22.2 Classical linear regressors

<table>
<thead>
<tr>
<th>class</th>
<th>Description</th>

<td>Linear model fitted by minimizing a regularized empirical loss with SGD</td>
</tr>
</tbody>
</table>

**sklearn.linear_model.LinearRegression**

**class sklearn.linear_model.LinearRegression(**kwargs**)**

Ordinary least squares Linear Regression.

LinearRegression fits a linear model with coefficients \(w = (w_1, \ldots, w_p)\) to minimize the residual sum of squares between the observed targets in the dataset, and the targets predicted by the linear approximation.

**Parameters**

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

- **normalize** [bool, default=False] This parameter is ignored when **fit_intercept** is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the L2-norm. If you wish to standardize, please use **StandardScaler** before calling **fit** on an estimator with **normalize=False**.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
**n_jobs** [int, default=None] The number of jobs to use for the computation. This will only provide speedup for n_targets > 1 and sufficient large problems. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**positive** [bool, default=False] When set to True, forces the coefficients to be positive. This option is only supported for dense arrays.

New in version 0.24.

**Attributes**

**coef_** [array of shape (n_features,) or (n_targets, n_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n_targets, n_features), while if only one target is passed, this is a 1D array of length n_features.

**rank_** [int] Rank of matrix X. Only available when X is dense.

**singular_** [array of shape (min(X, y),)] Singular values of X. Only available when X is dense.

**intercept_** [float or array of shape (n_targets,)] Independent term in the linear model. Set to 0.0 if fit_intercept = False.

See also:

**Ridge** Ridge regression addresses some of the problems of Ordinary Least Squares by imposing a penalty on the size of the coefficients with l2 regularization.

**Lasso** The Lasso is a linear model that estimates sparse coefficients with l1 regularization.

**ElasticNet** Elastic-Net is a linear regression model trained with both l1 and l2 -norm regularization of the coefficients.

**Notes**

From the implementation point of view, this is just plain Ordinary Least Squares (scipy.linalg.lstsq) or Non Negative Least Squares (scipy.optimize.nnls) wrapped as a predictor object.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> X = np.array([[1, 1], [1, 2], [2, 2], [2, 3]])
>>> # y = 1 * x_0 + 2 * x_1 + 3
>>> y = np.dot(X, np.array([1, 2])) + 3
>>> reg = LinearRegression().fit(X, y)
>>> reg.score(X, y)
1.0
>>> reg.coef_.array([1., 2.])
>>> reg.intercept_
3.0000...
>>> reg.predict(np.array([3, 5]))
array([16.])
```

</tbody>
</table>

**fit** ($X, y, sample_weight=None$)

Fit linear model.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtype if necessary
- **sample_weight** [array-like of shape (n_samples,), default=None] Individual weights for each sample

New in version 0.17: parameter `sample_weight` support to `LinearRegression`.

**Returns**

- **self** [returns an instance of self.]

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** ($X$)

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score** ($X, y, sample_weight=None$)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.LinearRegression

- Principal Component Regression vs Partial Least Squares Regression
- Plot individual and voting regression predictions
- Ordinary Least Squares and Ridge Regression Variance
- Logistic function
- Non-negative least squares
- Linear Regression Example
- Robust linear model estimation using RANSAC
- Sparsity Example: Fitting only features 1 and 2
- Theil-Sen Regression
- Robust linear estimator fitting
- Automatic Relevance Determination Regression (ARD)
- Bayesian Ridge Regression
- Isotonic Regression
- Face completion with a multi-output estimators
• Plotting Cross-Validated Predictions
• Underfitting vs. Overfitting
• Using KBinsDiscretizer to discretize continuous features

sklearn.linear_model.Ridge

class sklearn.linear_model.Ridge(**kwargs)

Linear least squares with l2 regularization.

Minimizes the objective function:

\[ \|y - Xw\|_2^2 + \alpha \cdot \|w\|_2^2 \]

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the L2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape (n_samples, n_targets)).

Read more in the User Guide.

Parameters

alpha [[float, ndarray of shape (n_targets,)], default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to \( \frac{1}{2C} \) in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

fit_intercept [bool, default=True] Whether to fit the intercept for this model. If set to false, no intercept will be used in calculations (i.e. X and y are expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the L2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. For ‘sparse_cg’ and ‘lsqr’ solvers, the default value is determined by scipy.sparse.linalg. For ‘sag’ solver, the default value is 1000.

tol [float, default=1e-3] Precision of the solution.

• ‘auto’ chooses the solver automatically based on the type of data.
• ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.
• ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.
• ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).
• ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
• ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale.

You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse_cg’ supports sparse input when fit_intercept is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance, default=None] Used when solver == ‘sag’ or ‘saga’ to shuffle the data. See Glossary for details.

New in version 0.17: random_state to support Stochastic Average Gradient.

Attributes

coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

n_iter_ [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

KernelRidge Kernel ridge regression combines ridge regression with the kernel trick.

Examples

```python
>>> from sklearn.linear_model import Ridge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = Ridge(alpha=1.0)
>>> clf.fit(X, y)
Ridge()
```
# Methods

</tr>
</tbody>
</table>

**fit** *(X, y, sample_weight=None)*  
Fit Ridge regression model.

**Parameters**

- **X** [[ndarray, sparse matrix] of shape (n_samples, n_features)] Training data
- **y** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values
- **sample_weight** [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

**Returns**

- **self** [returns an instance of self.]

**get_params**(deep=True)  
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict**(X)  
Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)  
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ^ 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ^ 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.Ridge

- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Prediction Latency
- Plot Ridge coefficients as a function of the regularization
- Ordinary Least Squares and Ridge Regression Variance
- Plot Ridge coefficients as a function of the L2 regularization
- Polynomial interpolation
- HuberRegressor vs Ridge on dataset with strong outliers
- Poisson regression and non-normal loss
- Common pitfalls in interpretation of coefficients of linear models

sklearn.linear_model.RidgeCV

class sklearn.linear_model.RidgeCV(**kwargs)

Ridge regression with built-in cross-validation.

See glossary entry for cross-validation estimator.

By default, it performs Leave-One-Out Cross-Validation, which is a form of efficient Leave-One-Out cross-validation.

Read more in the User Guide.

Parameters
alphas [ndarray of shape (n_alphas,), default=(0.1, 1.0, 10.0)] Array of alpha values to try. Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $1 / (2C)$ in other linear models such as LogisticRegression or LinearSVC. If using Leave-One-Out cross-validation, alphas must be positive.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

scoring [string, callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y). If None, the negative mean squared error if cv is 'auto' or None (i.e. when using leave-one-out cross-validation), and r2 score otherwise.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- None, to use the efficient Leave-One-Out cross-validation
- integer, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if y is binary or multiclass, StratifiedKFold is used, else, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

gcv_mode [{‘auto’, ‘svd’, eigen’}, default=’auto’] Flag indicating which strategy to use when performing Leave-One-Out Cross-Validation. Options are:

```python
'auto' : use 'svd' if n_samples > n_features, otherwise use 'eigen'
'svd' : force use of singular value decomposition of X when X is dense, eigenvalue decomposition of X^T.X when X is sparse.
'eigen' : force computation via eigendecomposition of X.X^T
```

The ‘auto’ mode is the default and is intended to pick the cheaper option of the two depending on the shape of the training data.

store_cv_values [bool, default=False] Flag indicating if the cross-validation values corresponding to each alpha should be stored in the cv_values_ attribute (see below). This flag is only compatible with cv=None (i.e. using Leave-One-Out Cross-Validation).

alpha_per_target [bool, default=False] Flag indicating whether to optimize the alpha value (picked from the alphas parameter list) for each target separately (for multi-output settings: multiple prediction targets). When set to True, after fitting, the alpha_ attribute will contain a value for each target. When set to False, a single alpha is used for all targets.

New in version 0.24.

Attributes

- cv_values_ [ndarray of shape (n_samples, n_alphas) or shape (n_samples, n_targets, n_alphas), optional] Cross-validation values for each alpha (only available if
store_cv_values=True and cv=None). After fit() has been called, this attribute will contain the mean squared errors (by default) or the values of the {loss, score}_func function (if provided in the constructor).

**coef_** [ndarray of shape (n_features) or (n_targets, n_features)] Weight vector(s).

**intercept_** [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

**alpha_** [float or ndarray of shape (n_targets,)] Estimated regularization parameter, or, if alpha_per_target=True, the estimated regularization parameter for each target.

**best_score_** [float or ndarray of shape (n_targets,)] Score of base estimator with best alpha, or, if alpha_per_target=True, a score for each target.

New in version 0.23.

See also:

*Ridge* Ridge regression.

*RidgeClassifier* Ridge classifier.

*RidgeClassifierCV* Ridge classifier with built-in cross validation.

**Examples**

```python
>>> from sklearn.datasets import load_diabetes
>>> from sklearn.linear_model import RidgeCV
>>> X, y = load_diabetes(return_X_y=True)
>>> clf = RidgeCV(alphas=[1e-3, 1e-2, 1e-1, 1]).fit(X, y)
>>> clf.score(X, y)
0.5166...
```

**Methods**

- `fit(X, y[, sample_weight])` Fit Ridge regression model with cv.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict using the linear model.
- `score(X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

**fit** *(X, y, sample_weight=0.0)*  
Fit Ridge regression model with cv.

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Training data. If using GCV, will be cast to float64 if necessary.

- **y** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtype if necessary.

- **sample_weight** [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

**Returns**
self [object]

Notes

When sample_weight is provided, the selected hyperparameter may depend on whether we use leave-one-out cross-validation (cv=None or cv='auto') or another form of cross-validation, because only leave-one-out cross-validation takes the sample weights into account when computing the validation score.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)

Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum ((y_{true} - y_{pred}) ** 2)$ and $v$ is the total sum of squares $\sum ((y_{true} - y_{true.mean}) ** 2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,)] or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.linear_model.RidgeCV`

- Combine predictors using stacking
- Common pitfalls in interpretation of coefficients of linear models
- Face completion with a multi-output estimators
- Effect of transforming the targets in regression model

`sklearn.linear_model.SGDRegressor`

class `sklearn.linear_model.SGDRegressor(**kwargs)`
Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the `User Guide`.

Parameters

loss [str, default='squared_loss'] The loss function to be used. The possible values are 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'

The ‘squared_loss’ refers to the ordinary least squares fit. ‘huber’ modifies ‘squared_loss’ to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. ‘epsilon_insensitive’ ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. ‘squared_epsilon_insensitive’ is the same but becomes squared loss past a tolerance of epsilon.

More details about the losses formulas can be found in the `User Guide`. 
penalty  [(‘l2’, ‘l1’, ‘elasticnet’), default=’l2’] The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

alpha  [float, default=0.0001] Constant that multiplies the regularization term. The higher the value, the stronger the regularization. Also used to compute the learning rate when set to learning_rate is set to ‘optimal’.

l1_ratio  [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Only used if penalty is ‘elasticnet’.

fit_intercept  [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter  [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

New in version 0.19.

tol  [float, default=1e-3] The stopping criterion. If it is not None, training will stop when (loss > best_loss - tol) for n_iter_no_change consecutive epochs.

New in version 0.19.

shuffle  [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose  [int, default=0] The verbosity level.

epsilon  [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if loss is ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

random_state  [int, RandomState instance, default=None] Used for shuffling the data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

learning_rate  [string, default=’invscaling’] The learning rate schedule:

- ‘constant’: eta = eta0
- ‘optimal’: eta = 1.0 / (alpha * (t + t0)) where t0 is chosen by a heuristic proposed by Leon Bottou.
- ‘invscaling’: eta = eta0 / pow(t, power_t)
- ‘adaptive’: eta = eta0, as long as the training keeps decreasing. Each time n_iter_no_change consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if early_stopping is True, the current learning rate is divided by 5.

New in version 0.20: Added ‘adaptive’ option

eta0  [double, default=0.01] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’ schedules. The default value is 0.01.

power_t  [double, default=0.25] The exponent for inverse scaling learning rate.

early_stopping  [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction
of training data as validation and terminate training when validation score returned by the score method is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20: Added ‘early_stopping’ option

**validation_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20: Added ‘validation_fraction’ option

**n_iter_no_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20: Added ‘n_iter_no_change’ option

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling fit resets this counter, while partial_fit will result in increasing the existing counter.

**average** [bool or int, default=False] When set to True, computes the averaged SGD weights across all updates and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

Attributes

**coef_** [ndarray of shape (n_features,)] Weights assigned to the features.

**intercept_** [ndarray of shape (1,)] The intercept term.

**average_coef_** [ndarray of shape (n_features,)] Averaged weights assigned to the features. Only available if average=True.

Deprecated since version 0.23: Attribute average_coef_ was deprecated in version 0.23 and will be removed in 0.25.

**average_intercept_** [ndarray of shape (1,)] The averaged intercept term. Only available if average=True.

Deprecated since version 0.23: Attribute average_intercept_ was deprecated in version 0.23 and will be removed in 0.25.

**n_iter_** [int] The actual number of iterations before reaching the stopping criterion.

**t_** [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

### Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import SGDRegressor
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)

# Always scale the input. The most convenient way is to use a pipeline.
>>> reg = make_pipeline(StandardScaler(),
...    SGDRegressor(max_iter=1000, tol=1e-3))
>>> reg.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('sgdregressor', SGDRegressor())])
```

</tbody>
</table>

**densify()**

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- `self` Fitted estimator.

**fit(X, y, coef_init=None, intercept_init=None, sample_weight=None)**

Fit linear model with Stochastic Gradient Descent.

**Parameters**

- **X**  
  [array-like, sparse matrix], shape (n_samples, n_features)] Training data

- **y**  
  [ndarray of shape (n_samples,)] Target values

- **coef_init**  
  [ndarray of shape (n_features,), default=None] The initial coefficients to warm-start the optimization.

- **intercept_init**  
  [ndarray of shape (1,), default=None] The initial intercept to warm-start the optimization.
sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns
self [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

partial_fit (X, y, sample_weight=None)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters
X [{array-like, sparse matrix}, shape (n_samples, n_features)] Subset of training data
y [numpy array of shape (n_samples,)] Subset of target values
sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns
self [returns an instance of self.]

predict (X)
Predict using the linear model

Parameters
X [{array-like, sparse matrix}, shape (n_samples, n_features)]

Returns
ndarray of shape (n_samples,) Predicted target values per element in X.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum ((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum ((y_{true} - y_{true.mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**kwargs)

Set and validate the parameters of estimator.

Parameters

**kwargs [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.SGDRegressor

- Prediction Latency
- SGD: Penalties
7.22.3 Regressors with variable selection

The following estimators have built-in variable selection fitting procedures, but any estimator using a L1 or elastic-net penalty also performs variable selection: typically SGDRegressor or SGDClassifier with an appropriate penalty.

### sklearn.linear_model.ElasticNet

class sklearn.linear_model.ElasticNet (**kwargs)

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

\[
\frac{1}{2n_samples} * ||y - Xw||^2_2 + \alpha * l1_ratio * ||w||_1 + 0.5 * \alpha * (1 - l1_ratio) * ||w||^2_2
\]

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

\[
a * L1 + b * L2
\]

where:

\[
alpha = a + b \quad \text{and} \quad l1\_ratio = a / (a + b)
\]

The parameter \(l1\_ratio\) corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. Specifically, \(l1\_ratio = 1\) is the lasso penalty. Currently, \(l1\_ratio \leq 0.01\) is not reliable, unless you supply your own sequence of alpha.

Read more in the User Guide.

**Parameters**

- `alpha` [float, default=1.0] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. `alpha = 0` is equivalent to an ordinary least square, solved by the `LinearRegression` object. For numerical reasons,
using alpha = 0 with the Lasso object is not advised. Given this, you should use the LinearRegression object.

**l1_ratio** [float, default=0.5] The ElasticNet mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an L2 penalty. For l1_ratio = 1 it is an L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

**fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

**normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**precompute** [bool or array-like of shape (n_features, n_features), default=False] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

**max_iter** [int, default=1000] The maximum number of iterations.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

**positive** [bool, default=False] When set to True, forces the coefficients to be positive.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == 'random'. Pass an int for reproducible output across multiple function calls. See Glossary.

**selection** ['cyclic', 'random', default='cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

**coef_[ndarray of shape (n_features,) or (n_targets, n_features)]** Parameter vector (w in the cost function formula).

**sparse_coef_[sparse matrix of shape (n_features,) or (n_tasks, n_features)]** Sparse representation of the fitted coef_.

**intercept_[float or ndarray of shape (n_targets,)** Independent term in decision function.

**n_iter_[list of int]** Number of iterations run by the coordinate descent solver to reach the specified tolerance.

**dual_gap_[float or ndarray of shape (n_targets,)** Given param alpha, the dual gaps at the end of the optimization, same shape as each observation of y.

See also:

**ElasticNetCV** Elastic net model with best model selection by cross-validation.

**SGDRegressor** Implements elastic net regression with incremental training.
SGDClassifier implements logistic regression with elastic net penalty
(SGDClassifier(loss="log", penalty="elasticnet")).

Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a
Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(random_state=0)
>>> print(regr.coef_)
[18.83816048 64.55968825]
>>> print(regr.intercept_)
1.451...
>>> print(regr.predict([[0, 0]]))
[1.451...]
```

Methods

- `fit(X, y, sample_weight, check_input)` Fit model with coordinate descent.
- `get_params([deep])` Get parameters for this estimator.
- `path(*args, **kwargs)` Compute elastic net path with coordinate descent.
- `predict(X)` Predict using the linear model.
- `score(X, y, sample_weight)` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

```python
fit (X, y, sample_weight=None, check_input=True)
Fit model with coordinate descent.
```

Parameters

- `X` ([ndarray, sparse matrix] of (n_samples, n_features)) Data.
- `y` ([ndarray, sparse matrix] of shape (n_samples,) or (n_samples, n_targets)) Target. Will be
cast to X’s dtypes if necessary.
- `sample_weight` [float or array-like of shape (n_samples,), default=None] Sample weight.
  
  New in version 0.23.
- `check_input` [bool, default=True] Allow to bypass several input checking. Don’t use this
  parameter unless you know what you do.
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path**(args, **kwargs)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 \\
+ \alpha \times \text{l1_ratio} \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - \text{l1_ratio}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\left(\frac{1}{(2 \times n_{\text{samples}})}\right) \times \frac{||Y - XW||_{\text{Fro}}}{2} \\
+ \alpha \times \text{l1_ratio} \times ||W||_{21} \\
+ 0.5 \times \alpha \times (1 - \text{l1_ratio}) \times ||W||_{\text{Fro}}^2
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the *User Guide*.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

- **y** [(array-like, sparse matrix) of shape (n_samples,) or (n_samples, n_outputs)] Target values.

- **l1_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

- **n_alphas** [int, default=100] Number of alphas along the regularization path.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.
precompute [‘auto’, bool or array-like of shape (n_features, n_features), default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coef_init [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coops [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X) Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
    Return the coefficient of determination $R^2$ of the prediction.
    The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares
    $((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares
    $((y_{true} - y_{true}.mean())**2).sum()$.
    The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).
    A constant model that always predicts the expected value of $y$, disregarding the input features, would get a
    $R^2$ score of 0.0.

Parameters
    X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this
    may be a precomputed kernel matrix or a list of generic objects instead with shape
    (n_samples, n_samples_fitted), where n_samples_fitted is the number
    of samples used in the fitting for the estimator.
    y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
    sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
    score [float] $R^2$ of self.predict(X) wrt. y.

Notes
    The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average'
    from version 0.23 to keep consistent with default value of r2_score. This influences the score method
    of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
    Set the parameters of this estimator.
    The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
    parameters of the form <component>__<parameter> so that it's possible to update each component
    of a nested object.

Parameters
    **params [dict] Estimator parameters.

Returns
    self [estimator instance] Estimator instance.

property sparse_coef_
    Sparse representation of the fitted coef_.

Examples using sklearn.linear_model.ElasticNet

- Release Highlights for scikit-learn 0.23
- Lasso and Elastic Net for Sparse Signals
- Train error vs Test error
sklearn.linear_model.ElasticNetCV

class sklearn.linear_model.ElasticNetCV(**kwargs)
Elastic Net model with iterative fitting along a regularization path.

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters

- **l1_ratio** [float or list of float, default=0.5] float between 0 and 1 passed to ElasticNet (scaling between l1 and l2 penalties). For l1_ratio = 0 the penalty is an L2 penalty. For l1_ratio = 1 it is an L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2. This parameter can be a list, in which case the different values are tested by cross-validation and the one giving the best prediction score is used. Note that a good choice of list of values for l1_ratio is often to put more values close to 1 (i.e. Lasso) and less close to 0 (i.e. Ridge), as in [.1, .5, .7, .9, .95, .99, 1].

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

- **n_alphas** [int, default=100] Number of alphas along the regularization path, used for each l1_ratio.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **max_iter** [int, default=1000] The maximum number of iterations.

- **tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

- **cv** [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - int, to specify the number of folds.
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
verbose [bool or int, default=0] Amount of verbosity.

n_jobs [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

positive [bool, default=False] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.

selection [{‘cyclic’, ‘random’}, default=’cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

alpha_ [float] The amount of penalization chosen by cross validation.

l1_ratio_ [float] The compromise between l1 and l2 penalization chosen by cross validation.

coeef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

intercept_ [float or ndarray of shape (n_targets, n_features)] Independent term in the decision function.

mse_path_ [ndarray of shape (n_l1_ratio, n_alpha, n_folds)] Mean square error for the test set on each fold, varying l1_ratio and alpha.

alphas_ [ndarray of shape (n_alphas,) or (n_l1_ratio, n_alphas)] The grid of alphas used for fitting, for each l1_ratio.

dual_gap_ [float] The dual gaps at the end of the optimization for the optimal alpha.

n_iter_ [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.

See also:

enet_path

ElasticNet

Notes

For an example, see examples/linear_model/plot_lasso_model_selection.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

The parameter l1_ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. More specifically, the optimization objective is:

\[
\frac{1}{2 \cdot n_{\text{samples}}} \cdot ||y - Xw||^2_2 + \alpha \cdot \text{l1_ratio} \cdot ||w||_1 + 0.5 \cdot \alpha \cdot (1 - \text{l1_ratio}) \cdot ||w||^2_2
\]

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:
\[ a \cdot L1 + b \cdot L2 \]

for:

\[ \text{alpha} = a + b \text{ and l1_ratio} = a / (a + b). \]

**Examples**

```python
>>> from sklearn.linear_model import ElasticNetCV
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNetCV(cv=5, random_state=0)
>>> regr.fit(X, y)
ElasticNetCV(cv=5, random_state=0)
>>> print(regr.alpha_)
0.199...
>>> print(regr.intercept_)
0.398...
>>> print(regr.predict([[0, 0]]))
[0.398...]
```

**Methods**

- `fit(X, y)` Fit linear model with coordinate descent.
- `get_params([deep])` Get parameters for this estimator.
- `path(*args, **kwargs)` Compute elastic net path with coordinate descent.
- `predict(X)` Predict using the linear model.
- `score(X, y[, sample_weight])` Return the coefficient of determination \( R^2 \) of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

**fit**

Fit linear model with coordinate descent.

- **Parameters**
  - `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.
  - `y` [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.

**get_params** *(deep=True)*

Get parameters for this estimator.

- **Parameters**
  - `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **get_params** *(deep=True)*
  - Returns

---

2190 Chapter 7. API Reference
params  [dict] Parameter names mapped to their values.

static path (*args, **kwargs)
  Compute elastic net path with coordinate descent.

  The elastic net optimization function varies for mono and multi-outputs.

  For mono-output tasks it is:

  \[
  \frac{1}{(2 \times n_{samples})} \times ||y - Xw||^2_2 \\
  + \alpha \times l1_{ratio} \times ||w||_1 \\
  + 0.5 \times \alpha \times (1 - l1_{ratio}) \times ||w||^2_2
  \]

  For multi-output tasks it is:

  \[
  \frac{1}{(2 \times n_{samples})} \times ||Y - XW||^{Fro}_2 \\
  + \alpha \times l1_{ratio} \times ||W||_{21} \\
  + 0.5 \times \alpha \times (1 - l1_{ratio}) \times ||W||^{Fro}_2
  \]

  Where:

  \[
  ||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
  \]

  i.e. the sum of norm of each row.

  Read more in the User Guide.

Parameters

X  [(array-like, sparse matrix) of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y  [(array-like, sparse matrix) of shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio  [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps  [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas  [int, default=100] Number of alphas along the regularization path.

alphas  [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

precompute  ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy  [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X  [bool, default=True] If True, X will be copied; else, it may be overwritten.

coef_init  [ndarray of shape (n_features,), default=None] The initial values of the coefficients.

verbose  [bool or int, default=False] Amount of verbosity.

return_n_iter  [bool, default=False] Whether to return the number of iterations or not.
positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when \(y.\text{ndim} == 1\)).

check_input [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coops [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

See also:

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict \((X)\)
Predict using the linear model.

Parameters

\(X\) [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

\(C\) [array, shape (n_samples,)] Returns predicted values.

score \((X, y, \text{sample_weight=None})\)
Return the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \(1 - \frac{u}{v}\), where \(u\) is the residual sum of squares (\(\sum(y_{true} - y_{pred})^2\)) and \(v\) is the total sum of squares (\(\sum(y_{true} - y_{true.mean})^2\)). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

Parameters

\(X\) [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

**sklearn.linear_model.Lars**

**class sklearn.linear_model.Lars(**kwargs**)

Least Angle Regression model a.k.a. LAR

Read more in the User Guide.

Parameters

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**verbose** [bool or int, default=False] Sets the verbosity amount.

**normalize** [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**precompute** [bool, ‘auto’ or array-like, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**n_nonzero_coefs** [int, default=500] Target number of non-zero coefficients. Use np.inf for no limit.

**eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.
scikit-learn user guide, Release 0.24.dev0

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

fit_path [bool, default=True] If True the full path is stored in the coef_path_ attribute. If you compute the solution for a large problem or many targets, setting fit_path to False will lead to a speedup, especially with a small alpha.

jitter [float, default=None] Upper bound on a uniform noise parameter to be added to the y values, to satisfy the model's assumption of one-at-a-time computations. Might help with stability.

New in version 0.23.

random_state [int, RandomState instance or None, default=None] Determines random number generation for jittering. Pass an int for reproducible output across multiple function calls. See Glossary. Ignored if jitter is None.

New in version 0.23.

Attributes

alphas_ [array-like of shape (n_alphas + 1,) or list of thereof of shape (n_targets,)] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.

active_ [list of shape (n_alphas,) or list of thereof of shape (n_targets,)] Indices of active variables at the end of the path.

coef_path_ [array-like of shape (n_features, n_alphas + 1) or list of thereof of shape (n_targets,)] The varying values of the coefficients along the path. It is not present if the fit_path parameter is False.

coef_ [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

intercept_ [float or array-like of shape (n_targets,)] Independent term in decision function.

n_iter_ [array-like or int] The number of iterations taken by lars_path to find the grid of alphas for each target.

See also:

lars_path, LarsCV
sklearn.decomposition.sparse_encode

Examples

```python
>>> from sklearn import linear_model
>>> reg = linear_model.Lars(n_nonzero_coefs=1)
>>> reg.fit([[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111])
Lars(n_nonzero_coefs=1)
>>> print(reg.coef_)
[ 0. -1.11...]
```
Methods

**fit**(X, y[, Xy])
Fit the model using X, y as training data.

**get_params**(deep=False)
Get parameters for this estimator.

**predict**(X)
Predict using the linear model.

**score**(X, y[, sample_weight])
Return the coefficient of determination $R^2$ of the prediction.

**set_params**(**params)
Set the parameters of this estimator.

**fit**(X, y, Xy=None)
Fit the model using X, y as training data.

Parameters:
- **X**  [array-like of shape (n_samples, n_features)] Training data.
- **y**  [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- **Xy**  [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] $Xy = np.dot(X.T, y)$ that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns:
- **self**  [object] returns an instance of self.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters:
- **deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns:
- **params**  [dict] Parameter names mapped to their values.

**predict**(X)
Predict using the linear model.

Parameters:
- **X**  [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns:
- **C**  [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{\text{true}} - y_{\text{pred}})^2).sum()$ and $v$ is the total sum of squares $((y_{\text{true}} - y_{\text{true}}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters:
- **X**  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape...
score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

sklearn.linear_model.LarsCV

class sklearn.linear_model.LarsCV(**kwargs)

Cross-validated Least Angle Regression model.

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

verbose [bool or int, default=False] Sets the verbosity amount.

max_iter [int, default=500] Maximum number of iterations to perform.

normalize [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

precompute [bool, ‘auto’ or array-like , default=’auto‘] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto‘ let us decide. The Gram matrix cannot be passed as argument since we will use only subsets of X.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross-validation,
• integer, to specify the number of folds.

• CV splitter,

• An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs,KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

max_n_alphas [int, default=1000] The maximum number of points on the path used to compute the residuals in the cross-validation

n_jobs [int or None, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

eps [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

Attributes

active_ [list of length n_alphas or list of thereof of shape (n_targets,)] Indices of active variables at the end of the path.

coeff_ [array-like of shape (n_features,)] parameter vector (w in the formulation formula)

intercept_ [float] independent term in decision function

coeff_path_ [array-like of shape (n_features, n_alphas)] the varying values of the coefficients along the path

alpha_ [float] the estimated regularization parameter alpha

alphas_ [array-like of shape (n_alphas,)] the different values of alpha along the path

cv_alphas_ [array-like of shape (n_cv_alphas,)] all the values of alpha along the path for the different folds

mse_path_ [array-like of shape (n_folds, n_cv_alphas)] the mean square error on left-out for each fold along the path (alpha values given by cv_alphas)

n_iter_ [array-like or int] the number of iterations run by Lars with the optimal alpha.

### fit(X, y)
Fit the model using X, y as training data.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,)] Target values.

**Returns**
- **self** [object] returns an instance of self.

### get_params(deep=True)
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [dict] Parameter names mapped to their values.

### predict(X)
Predict using the linear model.

**Parameters**
- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**
- **C** [array, shape (n_samples,)] Returns predicted values.

### score(X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares ($(y_{\text{true}} - y_{\text{pred}})^2 \cdot \text{sum()}$) and $v$ is the total sum of squares ($(y_{\text{true}} - y_{\text{true}.\text{mean}})^2 \cdot \text{sum()}$). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of $r2\_score$. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**sklearn.linear_model.Lasso**

**class sklearn.linear_model.Lasso(**kwargs**)

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

$$(1 / (2 \times n_{\text{samples}})) \times ||y - Xw||^2_2 + \alpha \times ||w||_1$$

Technically the Lasso model is optimizing the same objective function as the Elastic Net with $l1\_ratio=1.0$ (no L2 penalty).

Read more in the User Guide.

**Parameters**

- **alpha** [float, default=1.0] Constant that multiplies the L1 term. Defaults to 1.0. $alpha = 0$ is equivalent to an ordinary least square, solved by the LinearRegression object. For
numerical reasons, using :math:`\alpha = 0` with the :class:`Lasso` object is not advised. Given this, you should use the :class:`LinearRegression` object.

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when **fit_intercept** is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use :class:`StandardScaler` before calling fit on an estimator with normalize=False.

**precompute** ['auto', bool or array-like of shape (n_features, n_features), default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**max_iter** [int, default=1000] The maximum number of iterations.

**tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

**positive** [bool, default=False] When set to True, forces the coefficients to be positive.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == 'random'. Pass an int for reproducible output across multiple function calls. See Glossary.

**selection** [{'cyclic', 'random'}, default='cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

**Attributes**

**coef_** [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

**dual_gap_** [float or ndarray of shape (n_targets,)] Given param alpha, the dual gaps at the end of the optimization, same shape as each observation of y.

**sparse_coef_** [sparse matrix of shape (n_features, 1) or (n_targets, n_features)] Sparse representation of the fitted coef_.

**intercept_** [float or ndarray of shape (n_targets,)] Independent term in decision function.

**n_iter_** [int or list of int] Number of iterations run by the coordinate descent solver to reach the specified tolerance.

- :func:`lasso_path`
- :class:`LassoLars`
- :class:`LassoCV`
LassoLarsCV

sklearn.decomposition.sparse_encode

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1)
>>> print(clf.coef_)
[0.85 0.]
>>> print(clf.intercept_)
0.15...
```

**fit** *(X, y, sample_weight=None, check_input=True)*

Fit model with coordinate descent.

Parameters

- **X** *(ndarray, sparse matrix) of (n_samples, n_features)* Data.
- **y** *(ndarray, sparse matrix) of shape (n_samples,) or (n_samples, n_targets)* Target. Will be cast to X’s dtype if necessary.
- **sample_weight** *(float or array-like of shape (n_samples,), default=None)* Sample weight. New in version 0.23.
- **check_input** *(bool, default=True)* Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters

  deep `bool`, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

  params `dict` Parameter names mapped to their values.

**static path** *(args, **kwargs)*

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{samples})} \times ||y - Xw||^2_2 \\
+ \alpha \times l1_{ratio} \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1_{ratio}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{samples})} \times ||Y - XW||^{Fro}_2 \\
+ \alpha \times l1_{ratio} \times ||W||_21 \\
+ 0.5 \times \alpha \times (1 - l1_{ratio}) \times ||W||^{Fro}_2
\]

Where:

\[||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}\]

e.i. the sum of norm of each row.

Read more in the *User Guide*.

Parameters

  X `[[array-like, sparse matrix] of shape (n_samples, n_features)]` Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

  y `[[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)]` Target values.

  l1_ratio `float`, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

  eps `float`, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

  n_alphas `int`, default=100] Number of alphas along the regularization path.

  alphas `ndarray`, default=None] List of alphas where to compute the models. If None alphas are set automatically.
scikit-learn user guide, Release 0.24.dev0

precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto']
Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coeff_init [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params [kwarg] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coefs [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iter [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X)
Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

ty [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

property sparse_coef_
Sparse representation of the fitted coef_.

Examples using sklearn.linear_model.Lasso

- Release Highlights for scikit-learn 0.23
- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Lasso on dense and sparse data
- Joint feature selection with multi-task Lasso
- Lasso and Elastic Net for Sparse Signals
• Cross-validation on diabetes Dataset Exercise

**sklearn.linear_model.LassoCV**

class sklearn.linear_model.LassoCV(**kwargs)

Lasso linear model with iterative fitting along a regularization path.

See glossary entry for cross-validation estimator.

The best model is selected by cross-validation.

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n\_samples)} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

**Parameters**

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

- **n_alphas** [int, default=100] Number of alphas along the regularization path.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto', let us decide. The Gram matrix can also be passed as argument.

- **max_iter** [int, default=1000] The maximum number of iterations.

- **tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

- **cv** [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - int, to specify the number of folds.
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, KFold is used.

Refer [User Guide](https://scikit-learn.org/stable/glossary.html#term-cross-validation-estimator) for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.
verbose  [bool or int, default=False] Amount of verbosity.

n_jobs  [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel Backend context. -1 means using all processors. See Glossary for more details.

positive  [bool, default=False] If positive, restrict regression coefficients to be positive.

random_state  [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.

selection  [[‘cyclic’, ‘random’], default=’cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

alpha_  [float] The amount of penalization chosen by cross validation.

coeff_  [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

intercept_  [float or ndarray of shape (n_targets,)] Independent term in decision function.

mse_path_  [ndarray of shape (n_alphas, n_folds)] Mean square error for the test set on each fold, varying alpha.

alphas_  [ndarray of shape (n_alphas,)] The grid of alphas used for fitting.

dual_gap_  [float or ndarray of shape (n_targets,)] The dual gap at the end of the optimization for the optimal alpha (alpha_).

n_iter_  [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.

**fit**(X, y)

Fit linear model with coordinate descent.

Fit is on grid of alphas and best alpha estimated by cross-validation.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.

- **y** ([array-like of shape (n_samples,) or (n_samples, n_targets)]) Target values.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path**(args, **kwargs)

Compute Lasso path with coordinate descent.

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times |y - Xw|^2 + \alpha \times |w|_1
\]

For multi-output tasks it is:
\[(1 / (2 \times n\_samples)) \times ||Y - XW||_2\_Fro + alpha \times ||W||_21\]

Where:

\[||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like, sparse matrix] of shape \((n\_samples, n\_features)\) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If \(y\) is mono-output then \(X\) can be sparse.

- **y** [array-like, sparse matrix] of shape \((n\_samples,)\) or \((n\_samples, n\_outputs)\) Target values

- **eps** [float, default=1e-3] Length of the path. \(\text{eps}=1e-3\) means that \(\alpha_{\text{min}} / \alpha_{\text{max}} = 1e-3\)

- **n\_alphas** [int, default=100] Number of alphas along the regularization path

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically

- **precompute** ['auto', bool or array-like of shape \((n\_features, n\_features)\), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **Xy** [array-like of shape \((n\_features,)\) or \((n\_features, n\_outputs)\), default=None] \(Xy = \text{np.dot}(X, y)\) that can be precomputed. It is useful only when the Gram matrix is precomputed.

- **copy\_X** [bool, default=True] If True, \(X\) will be copied; else, it may be overwritten.

- **coef\_init** [ndarray of shape \((n\_features,)\), default=None] The initial values of the coefficients.

- **verbose** [bool or int, default=False] Amount of verbosity.

- **return\_n\_iter** [bool, default=False] whether to return the number of iterations or not.

- **positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when \(y\).ndim == 1).

- ****params** [kwargs] keyword arguments passed to the coordinate descent solver.

**Returns**

- **alphas** [ndarray of shape \((n\_alphas,)\)] The alphas along the path where models are computed.

- **coefs** [ndarray of shape \((n\_features, n\_alphas)\) or \((n\_outputs, n\_features, n\_alphas)\)] Coefficients along the path.

- **dual\_gaps** [ndarray of shape \((n\_alphas,)\)] The dual gaps at the end of the optimization for each alpha.

- **n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

lars_path
Lasso
LassoLars
LassoCV
LassoLarsCV
sklearn.decomposition.sparse_encode

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by lars_path

Examples

Comparing lasso_path and lars_path with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0. 0. 0.46874778]
 [0.2159048 0.4425765 0.23689075]]
```

```python
>>> # Now use lars_path and 1D linear interpolation to compute the same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
... coef_path_lars[:, ::-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[0. 0. 0.46874778]
 [0.2159048 0.4425765 0.23668876]]
```

predict(X)

Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum ((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum ((y_{true} - y_{true.mean()})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] $R^2$ of self.predict(X) wrt. $y$.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form $<component>__<parameter>$ so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

**self** [estimator instance] Estimator instance.

Examples using sklearn.linear_model.LassoCV

- Combine predictors using stacking
- Model-based and sequential feature selection
- Lasso model selection: Cross-Validation / AIC / BIC
- Common pitfalls in interpretation of coefficients of linear models
- Cross-validation on diabetes Dataset Exercise
sklearn.linear_model.LassoLars

class sklearn.linear_model.LassoLars(**kwargs)

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

$ \frac{1}{(2 + n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1$

Read more in the User Guide.

Parameters

- **alpha** [float, default=1.0] Constant that multiplies the penalty term. Defaults to 1.0. alpha = 0 is equivalent to an ordinary least square, solved by LinearRegression. For numerical reasons, using alpha = 0 with the LassoLars object is not advised and you should prefer the LinearRegression object.

- **fit_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- **verbose** [bool or int, default=False] Sets the verbosity amount.

- **normalize** [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

- **precompute** [bool, ‘auto’ or array-like, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.

- **max_iter** [int, default=500] Maximum number of iterations to perform.

- **eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

- **fit_path** [bool, default=True] If True the full path is stored in the coef_path_ attribute. If you compute the solution for a large problem or many targets, setting fit_path to False will lead to a speedup, especially with a small alpha.

- **positive** [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

- **jitter** [float, default=None] Upper bound on a uniform noise parameter to be added to the y values, to satisfy the model’s assumption of one-at-a-time computations. Might help with stability.

New in version 0.23.
random_state [int, RandomState instance or None, default=None] Determines random number
generation for jittering. Pass an int for reproducible output across multiple function calls.
See Glossary. Ignored if jitter is None.

New in version 0.23.

Attributes

alphas_ [array-like of shape (n_alphas + 1,) or list of thereof of shape (n_targets,)] Maximum
of covariances (in absolute value) at each iteration. n_alphas is either max_iter,
n_features or the number of nodes in the path with alpha >= alpha_min,
whichever is smaller.

active_ [list of length n_alphas or list of thereof of shape (n_targets,)] Indices of active variables
at the end of the path.

coeff_path_ [array-like of shape (n_features, n_alphas + 1) or list of thereof of shape
(n_targets,)] If a list is passed it’s expected to be one of n_targets such arrays. The varying
values of the coefficients along the path. It is not present if the fit_path parameter is
False.

coeff_ [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the
formulation formula).

intercept_ [float or array-like of shape (n_targets,)] Independent term in decision function.

n_iter_ [array-like or int] The number of iterations taken by lars_path to find the grid of alphas
for each target.

</tbody>
</table>

### fit(X, y, Xy=None)

Fit the model using X, y as training data.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Training data.
- y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- Xy [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

**Returns**

### get_params(deep=True)

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

### predict(X)

Predict using the linear model.

**Parameters**

- X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- C [array, shape (n_samples,)] Returns predicted values.

### score(X, y, sample_weight=None)

Return the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \((1 - \frac{u}{v})\), where \(u\) is the residual sum of squares \(((y_{true} - y_{pred}) ** 2).sum()\) and \(v\) is the total sum of squares \(((y_{true} - y_{true}.mean()) ** 2).sum()\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape...
(n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of $r2_score$. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

sklearn.linear_model.LassoLarsCV
class sklearn.linear_model.LassoLarsCV(**kwargs)
Cross-validated Lasso, using the LARS algorithm.

See glossary entry for cross-validation estimator.

The optimization objective for Lasso is:

$$(1 / (2 * n_samples)) \times ||y - Xw||^2_2 + alpha \times ||w||_1$$

Read more in the User Guide.

Parameters

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

verbose [bool or int, default=False] Sets the verbosity amount.

max_iter [int, default=500] Maximum number of iterations to perform.

normalize [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

precompute [bool or 'auto', default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix cannot be passed as argument since we will use only subsets of X.

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.
- `CV splitter`,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, `KFold` is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**max_n_alphas** [int, default=1000] The maximum number of points on the path used to compute the residuals in the cross-validation

**n_jobs** [int or None, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**positive** [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove `fit_intercept` which is set True by default. Under the positive restriction the model coefficients do not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator. As a consequence using LassoLarsCV only makes sense for problems where a sparse solution is expected and/or reached.

**Attributes**

- **coef_** [array-like of shape (n_features,)] parameter vector (w in the formulation formula)
- **intercept_** [float] independent term in decision function.
- **coef_path_** [array-like of shape (n_features, n_alphas)] the varying values of the coefficients along the path
- **alpha_** [float] the estimated regularization parameter alpha
- **alphas_** [array-like of shape (n_alphas,)] the different values of alpha along the path
- **cv_alphas_** [array-like of shape (n_cv_alphas,)] all the values of alpha along the path for the different folds
- **mse_path_** [array-like of shape (n_folds, n_cv_alphas)] the mean square error on left-out for each fold along the path (alpha values given by `cv_alphas_`)
- **n_iter_** [array-like or int] the number of iterations run by Lars with the optimal alpha.
- **active_** [list of int] Indices of active variables at the end of the path.

See also:
**lars_path, LassoLars, LarsCV, LassoCV**

**Notes**

The object solves the same problem as the LassoCV object. However, unlike the LassoCV, it finds the relevant alphas values by itself. In general, because of this property, it will be more stable. However, it is more fragile to heavily multicollinear datasets.

It is more efficient than the LassoCV if only a small number of features are selected compared to the total number, for instance if there are very few samples compared to the number of features.

**Examples**

```python
>>> from sklearn.linear_model import LassoLarsCV
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(noise=4.0, random_state=0)
>>> reg = LassoLarsCV(cv=5).fit(X, y)
>>> reg.score(X, y)
0.9992...
>>> reg.alpha_
0.0484...
>>> reg.predict(X[:1,])
array([-77.8723...])
```

**Methods**

<table>

</tbody>
</table>

**fit(X, y)**

Fit the model using X, y as training data.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Training data.
- y [array-like of shape (n_samples,)] Target values.

**Returns**

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
**params**  [dict] Parameter names mapped to their values.

**predict**  (*X*)
Predict using the linear model.

- **Parameters**
  - *X*  [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

- **Returns**
  - *C*  [array, shape (n_samples,)] Returns predicted values.

**score**  (*X, y, sample_weight=None*)
Return the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \((1 - \frac{u}{v})\), where \(u\) is the residual sum of squares \(\sum((y_{true} - y_{pred})^2)\) and \(v\) is the total sum of squares \(\sum((y_{true} - y_{true}.mean())^2)\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

- **Parameters**
  - *X*  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
  - *y*  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for *X*.
  - *sample_weight*  [array-like of shape (n_samples,), default=None] Sample weights.

- **Returns**
  - *score*  [float] \(R^2\) of self.predict (*X*) wrt. *y*.

**Notes**

The \(R^2\) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**  (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

- **Parameters**
  - **params**  [dict] Estimator parameters.

- **Returns**
Examples using `sklearn.linear_model.LassoLarsCV`

- Lasso model selection: Cross-Validation / AIC / BIC

`sklearn.linear_model.LassoLarsIC`  

```python
class sklearn.linear_model.LassoLarsIC(**kwargs)
Lasso model fit with Lars using BIC or AIC for model selection

The optimization objective for Lasso is:

\[(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1\]
```

AIC is the Akaike information criterion and BIC is the Bayes Information criterion. Such criteria are useful to select the value of the regularization parameter by making a trade-off between the goodness of fit and the complexity of the model. A good model should explain well the data while being simple.

**Parameters**

- `criterion` [str, default='aic'] The type of criterion to use.
- `fit_intercept` [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- `verbose` [bool or int, default=False] Sets the verbosity amount.
- `normalize` [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- `precompute` [bool, ‘auto’ or array-like, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- `max_iter` [int, default=500] Maximum number of iterations to perform. Can be used for early stopping.
- `eps` [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.
- `copy_X` [bool, default=True] If True, X will be copied; else, it may be overwritten.
- `positive` [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients do not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()`) when `fit_path=True` reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator. As a consequence using `LassoLarsIC` only makes sense for problems where a sparse solution is expected and/or reached.

**Attributes**

- `coef_` [array-like of shape (n_features,)] parameter vector (w in the formulation formula)
- `intercept_` [float] independent term in decision function.
alpha_ [float] the alpha parameter chosen by the information criterion

alphas_ [array-like of shape (n_alphas + 1,) or list thereof] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller. If a list, it will be of length n_targets.

n_iter_ [int] number of iterations run by lars_path to find the grid of alphas.

criterion_ [array-like of shape (n_alphas,)] The value of the information criteria ('aic', 'bic') across all alphas. The alpha which has the smallest information criterion is chosen. This value is larger by a factor of n_samples compared to Eqns. 2.15 and 2.16 in (Zou et al, 2007).

See also:

lars_path, LassoLars, LassoLarsCV

Notes

The estimation of the number of degrees of freedom is given by:

Examples

```python
>>> from sklearn import linear_model
>>> reg = linear_model.LassoLarsIC(criterion='bic')
>>> reg.fit([[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111])
LassoLarsIC(criterion='bic')
>>> print(reg.coef_)
[ 0. -1.11...]
```

</tbody>
</table>

**fit (X, y, copy_X=None)**

Fit the model using X, y as training data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] training data.
- **y** [array-like of shape (n_samples,)] target values. Will be cast to X’s dtype if necessary
copy_X [bool, default=None] If provided, this parameter will override the choice of copy_X made at instance creation. If True, X will be copied; else, it may be overwritten.

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean>()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.linear_model.LassoLarsIC`

- Lasso model selection: Cross-Validation / AIC / BIC

`sklearn.linear_model.OptimalMatchingPursuit`

class sklearn.linear_model.OptimalMatchingPursuit (**kwargs)

Orthogonal Matching Pursuit model (OMP).

Read more in the User Guide.

Parameters

- n_nonzero_coefs [int, default=None] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
- tol [float, default=None] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.
- fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- normalize [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the 2-norm. If you wish to standardize, please use `StandardScaler` before calling fit on an estimator with normalize=False.
- precompute ['auto' or bool, default='auto'] Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when n_targets or n_samples is very large. Note that if you already have such matrices, you can pass them directly to the fit method.

Attributes

- coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formula).
- intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function.
- n_iter_ [int or array-like] Number of active features across every target.

Examples

```python
>>> from sklearn.linear_model import OrthogonalMatchingPursuit
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(noise=4, random_state=0)

>>> reg = OrthogonalMatchingPursuit().fit(X, y)

>>> reg.score(X, y)
0.9991...

>>> reg.predict(X[:1,:])
array([-78.3854...])
```

Methods

- `fit(X, y)`
  - Fit the model using X, y as training data.

- `get_params([deep])`
  - Get parameters for this estimator.

- `predict(X)`
  - Predict using the linear model.

- `score(X, y[, sample_weight])`
  - Return the coefficient of determination $R^2$ of the prediction.

- `set_params(**params)`
  - Set the parameters of this estimator.

```python
fit (X, y)
  Fit the model using X, y as training data.

Parameters

- X [array-like of shape (n_samples, n_features)] Training data.
- y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtypes if necessary
```
Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())**2).sum()$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this
may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number
of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average'
from version 0.23 to keep consistent with default value of r2_score. This influences the score method
of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.linear_model.OrthogonalMatchingPursuit`

- Orthogonal Matching Pursuit

`sklearn.linear_model.OrthogonalMatchingPursuitCV`

See glossary entry for `cross-validation estimator`.

Read more in the *User Guide*.

Parameters

- `copy` [bool, default=True] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.

- `fit_intercept` [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- `normalize` [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling fit on an estimator with `normalize=False`.

- `max_iter` [int, default=None] Maximum numbers of iterations to perform, therefore maximum features to include. 10% of `n_features` but at least 5 if available.

- `cv` [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - integer, to specify the number of folds,
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- `n_jobs` [int, default=None] Number of CPUs to use during the cross validation. `None` means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

- `verbose` [bool or int, default=False] Sets the verbosity amount.

Attributes

- `intercept_` [float or ndarray of shape (n_targets,)] Independent term in decision function.
coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the problem formulation).

n_nonzero_coefs_ [int] Estimated number of non-zero coefficients giving the best mean squared error over the cross-validation folds.

n_iter_ [int or array-like] Number of active features across every target for the model refit with the best hyperparameters got by cross-validating across all folds.

fit (X, y)

Fit the model using X, y as training data.

Parameters

X [array-like of shape (n_samples, n_features)] Training data.
```
y [array-like of shape (n_samples,)] Target values. Will be cast to X’s dtype if necessary.

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters
depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

predict (X)
Predict using the linear model.

Parameters
X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$.
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A
constant model that always predicts the expected value of y, disregarding the input features, would get a
$R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this
may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number
of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes
The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average'
from version 0.23 to keep consistent with default value of r2_score. This influences the score method
of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### Examples using `sklearn.linear_model.OrthogonalMatchingPursuitCV`

</tbody>
</table>

#### `sklearn.linear_model.ARDRegression`

**class sklearn.linear_model.ARDRegression(**kwargs)**

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization)

Read more in the User Guide.

**Parameters**

- **n_iter** [int, default=300] Maximum number of iterations.
- **tol** [float, default=1e-3] Stop the algorithm if w has converged.
- **alpha_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.
- **alpha_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.
- **lambda_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.
- **lambda_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.
- **compute_score** [bool, default=False] If True, compute the objective function at each step of the model.
- **threshold_lambda** [float, default=10 000] threshold for removing (pruning) weights with high precision from the computation.
**fit_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**verbose** [bool, default=False] Verbose mode when fitting the model.

**Attributes**

- **coef_** [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)
- **alpha_** [float] estimated precision of the noise.
- **lambda_** [array-like of shape (n_features,)] estimated precisions of the weights.
- **sigma_** [array-like of shape (n_features, n_features)] estimated variance-covariance matrix of the weights
- **scores_** [float] if computed, value of the objective function (to be maximized)
- **intercept_** [float] Independent term in decision function. Set to 0.0 if fit_intercept = False.

**Notes**

For an example, see examples/linear_model/plot_ard.py.

**References**

D. J. C. MacKay, Bayesian nonlinear modeling for the prediction competition, ASHRAE Transactions, 1994.

R. Salakhutdinov, Lecture notes on Statistical Machine Learning, http://www.utstat.toronto.edu/~rsalakhu/sta4273/notes/Lecture2.pdf#page=15 Their beta is our self.alpha_. Their alpha is our self.lambda_. ARD is a little different than the slide: only dimensions/features for which self.lambda_ < self.threshold_lambda are kept and the rest are discarded.

**Examples**

```python
>>> from sklearn import linear_model
>>> clf = linear_model.ARDRegression()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
ARDRegression()
>>> clf.predict([[1, 1]])
array([1.])
```

**fit** $(X, y)$

Fit the ARDRegression model according to the given training data and parameters.

Iterative procedure to maximize the evidence

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values (integers). Will be cast to X’s dtype if necessary

**Returns**

- **self** [returns an instance of self.]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** $(X, return_std=False)$

Predict using the linear model. In addition to the mean of the predictive distribution, also its standard deviation can be returned.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.
- **return_std** [bool, default=False] Whether to return the standard deviation of posterior prediction.

**Returns**

- **y_mean** [array-like of shape (n_samples,)] Mean of predictive distribution of query points.
- **y_std** [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.

**score** $(X, y, sample_weight=None)$

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. 

7.22. sklearn.linear_model: Linear Models
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for $X$.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**) 
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.linear_model.ARDRegression**

- *Automatic Relevance Determination Regression (ARD)*

**sklearn.linear_model.BayesianRidge**

class sklearn.linear_model.BayesianRidge(**kwargs)

Bayesian ridge regression.

Fit a Bayesian ridge model. See the Notes section for details on this implementation and the optimization of the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the User Guide.

**Parameters**

- **n_iter** [int, default=300] Maximum number of iterations. Should be greater than or equal to 1.
- **tol** [float, default=1e-3] Stop the algorithm if w has converged.
**alpha** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.

**lambda** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.

**alpha_init** [float, default=None] Initial value for alpha (precision of the noise). If not set, alpha_init is 1/Var(y).

   New in version 0.22.

**lambda_init** [float, default=None] Initial value for lambda (precision of the weights). If not set, lambda_init is 1.

   New in version 0.22.

**compute_score** [bool, default=False] If True, compute the log marginal likelihood at each iteration of the optimization.

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. The intercept is not treated as a probabilistic parameter and thus has no associated variance. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**verbose** [bool, default=False] Verbose mode when fitting the model.

**Attributes**

**coef_** [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)

**intercept_** [float] Independent term in decision function. Set to 0.0 if fit_intercept = False.

**alpha_** [float] Estimated precision of the noise.

**lambda_** [float] Estimated precision of the weights.

**sigma_** [array-like of shape (n_features, n_features)] Estimated variance-covariance matrix of the weights

**scores_** [array-like of shape (n_iter_+1,)] If computed_score is True, value of the log marginal likelihood (to be maximized) at each iteration of the optimization. The array starts with the value of the log marginal likelihood obtained for the initial values of alpha and lambda and ends with the value obtained for the estimated alpha and lambda.

**n_iter_** [int] The actual number of iterations to reach the stopping criterion.
Notes

There exist several strategies to perform Bayesian ridge regression. This implementation is based on the algorithm described in Appendix A of (Tipping, 2001) where updates of the regularization parameters are done as suggested in (MacKay, 1992). Note that according to A New View of Automatic Relevance Determination (Wipf and Nagarajan, 2008) these update rules do not guarantee that the marginal likelihood is increasing between two consecutive iterations of the optimization.

References

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.BayesianRidge()
>>> clf.fit([[0, 0], [1, 1], [2, 2]], [0, 1, 2])
BayesianRidge()
>>> clf.predict([[1, 1]])
array([1.])
```

**fit (X, y, sample_weight=none)**
Fit the model

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Training data
- **y** [ndarray of shape (n_samples,)] Target values. Will be cast to X’s dtype if necessary
- **sample_weight** [ndarray of shape (n_samples,), default=None] Individual weights for each sample

New in version 0.20: parameter `sample_weight` support to BayesianRidge.

**Returns**

- **self** [returns an instance of self.]

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X, return_std=False)
Predict using the linear model.
In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Samples.

return_std [bool, default=False] Whether to return the standard deviation of posterior prediction.

Returns

y_mean [array-like of shape (n_samples,)] Mean of predictive distribution of query points.
y_std [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### 7.22.5 Multi-task linear regressors with variable selection

These estimators fit multiple regression problems (or tasks) jointly, while inducing sparse coefficients. While the inferred coefficients may differ between the tasks, they are constrained to agree on the features that are selected (non-zero coefficients).

```python
linear_model.MultiTaskLasso(**kwargs) Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.
linear_model.MultiTaskLassoCV(**kwargs) Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.
```

### sklearn.linear_model.MultiTaskElasticNet

#### class sklearn.linear_model.MultiTaskElasticNet(**kwargs)

Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for MultiTaskElasticNet is:

\[
\frac{1}{(2 \times n\_samples)} \times ||Y - XW||\_Fro^2 + \alpha \times l1\_ratio \times ||W||\_21 + 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||\_Fro^2
\]

Where:

\[
||W||\_21 = \sum_i \sqrt{\sum_j W\_ij^2}
\]

i.e. the sum of norms of each row.

Read more in the User Guide.

**Parameters**

- **alpha** [float, default=1.0] Constant that multiplies the L1/L2 term. Defaults to 1.0.
- **l1_ratio** [float, default=0.5] The ElasticNet mixing parameter, with 0 < l1_ratio <= 1. For l1_ratio = 1 the penalty is an L1/L2 penalty. For l1_ratio = 0 it is an L2 penalty. For 0 <
l1_ratio < 1, the penalty is a combination of L1/L2 and L2.

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**max_iter** [int, default=1000] The maximum number of iterations.

**tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.

**selection** [['cyclic', 'random'], default='cyclic'] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

**Attributes**

- **intercept_** [ndarray of shape (n_tasks,)] Independent term in decision function.
- **coef_** [ndarray of shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), coef_ is then a 1D array. Note that coef_ stores the transpose of W, W.T.
- **n_iter_** [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance.
- **dual_gap_** [float] The dual gaps at the end of the optimization.
- **eps_** [float] The tolerance scaled scaled by the variance of the target y.
- **sparse_coef_** [sparse matrix of shape (n_features,) or (n_tasks, n_features)] Sparse representation of the fitted coef_.

**See also:**

- ElasticNet
- MultiTaskLasso
Notes

The algorithm used to fit the model is coordinate descent.
To avoid unnecessary memory duplication the X and y arguments of the fit method should be directly passed as Fortran-contiguous numpy arrays.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0, 0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskElasticNet(alpha=0.1)
>>> print(clf.coef_)
[[0.45663524 0.45612256]
 [0.45663524 0.45612256]]
>>> print(clf.intercept_)
[0.0872422 0.0872422]
```

Methods

- `fit(X, y)` Fit MultiTaskElasticNet model with coordinate descent
- `get_params([deep])` Get parameters for this estimator.
- `path(*args, **kwargs)` Compute elastic net path with coordinate descent.
- `predict(X)` Predict using the linear model.
- `score(X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

**fit (X, y)**

Fit MultiTaskElasticNet model with coordinate descent

**Parameters**

- `X` [ndarray of shape (n_samples, n_features)] Data.
- `y` [ndarray of shape (n_samples, n_tasks)] Target. Will be cast to X’s dtype if necessary.

**Notes**

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
params [dict] Parameter names mapped to their values.

static path (*args, **kwargs)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{2n_{\text{samples}}} \|y - Xw\|_2^2 \\
+ \alpha \times \text{l1_ratio} \times \|w\|_1 \\
+ 0.5 \times \alpha \times (1 - \text{l1_ratio}) \times \|w\|_2^2
\]

For multi-output tasks it is:

\[
\frac{1}{2n_{\text{samples}}} \|Y - XW\|_{\text{Fro}}^2 \\
+ \alpha \times \text{l1_ratio} \times \|W\|_{21} \\
+ 0.5 \times \alpha \times (1 - \text{l1_ratio}) \times \|W\|_{\text{Fro}}^2
\]

Where:

\[
\|W\|_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [(array-like, sparse matrix) of shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, default=100] Number of alphas along the regularization path.

alphas [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coef_init [ndarray of shape (n_features,), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.
**positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

**check_input** [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params** [kwargs] Keyword arguments passed to the coordinate descent solver.

**Returns**

- **alphas** [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.
- **coefs** [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.
- **dual_gaps** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
- **n_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

See also:

- MultiTaskElasticNet
- MultiTaskElasticNetCV
- ElasticNet
- ElasticNetCV

**Notes**

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

**predict**(X)

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean()})**2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

property sparse_coef_

Sparse representation of the fitted coef_.

sklearn.linear_model.MultiTaskElasticNetCV

class sklearn.linear_model.MultiTaskElasticNetCV(**kwargs)

Multi-task L1/L2 ElasticNet with built-in cross-validation.

See glossary entry for cross-validation estimator.

The optimization objective for MultiTaskElasticNet is:

$$(1 / (2 * n_samples)) * ||Y - XW||^Fro_2 + alpha * l1_ratio * ||W||_21 + 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2$$

Where:

$$||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the User Guide.

New in version 0.15.

Parameters
**l1_ratio** [float or list of float, default=0.5] The ElasticNet mixing parameter, with $0 < \text{l1\_ratio} < 1$. For $\text{l1\_ratio} = 1$ the penalty is an L1/L2 penalty. For $\text{l1\_ratio} = 0$ it is an L2 penalty. For $0 < \text{l1\_ratio} < 1$, the penalty is a combination of L1/L2 and L2. This parameter can be a list, in which case the different values are tested by cross-validation and the one giving the best prediction score is used. Note that a good choice of list of values for l1_ratio is often to put more values close to 1 (i.e. Lasso) and less close to 0 (i.e. Ridge), as in [.1, .5, .7, .9, .95, .99, 1]

**eps** [float, default=1e-3] Length of the path. eps=1e-3 means that $\alpha_{\text{min}} / \alpha_{\text{max}} = 1e^{-3}$.

**n_alphas** [int, default=100] Number of alphas along the regularization path.

**alphas** [array-like, default=None] List of alphas where to compute the models. If not provided, set automatically.

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**max_iter** [int, default=1000] The maximum number of iterations.

**tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

**cv** [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- int, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here. Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**verbose** [bool or int, default=0] Amount of verbosity.

**n_jobs** [int, default=None] Number of CPUs to use during the cross validation. Note that this is used only if multiple values for l1_ratio are given. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.

**selection** [‘cyclic’, ‘random’, default=’cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.
Attributes

- **intercept_** [ndarray of shape (n_tasks,)] Independent term in decision function.
- **coef_** [ndarray of shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). Note that coef_ stores the transpose of W, W.T.
- **alpha_** [float] The amount of penalization chosen by cross validation.
- **mse_path_** [ndarray of shape (n_alphas, n_folds) or (n_l1_ratio, n_alphas, n_folds)] Mean square error for the test set on each fold, varying alpha.
- **alphas_** [ndarray of shape (n_alphas,) or (n_l1_ratio, n_alphas)] The grid of alphas used for fitting, for each l1_ratio.
- **l1_ratio_** [float] Best l1_ratio obtained by cross-validation.
- **n_iter_** [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.
- **dual_gap_** [float] The dual gap at the end of the optimization for the optimal alpha.

See also:

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X and y arguments of the fit method should be directly passed as Fortran-contiguous numpy arrays.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNetCV(cv=3)
>>> clf.fit([[0, 0], [1, 1], [2, 2]], ...
[0, 0], [1, 1], [2, 2]))
MultiTaskElasticNetCV(cv=3)
>>> print(clf.coef_)
[[0.52875032 0.46958558]
 [0.52875032 0.46958558]]
>>> print(clf.intercept_)
[0.00166409 0.00166409]
```

**fit (X, y)**

Fit linear model with coordinate descent.

Fit is on grid of alphas and best alpha estimated by cross-validation.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path(*args, **kwargs)**

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times \|y - Xw\|^2_2 \\
+ \alpha \times l1_{\text{ratio}} \times \|w\|_1 \\
+ 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times \|w\|^2_2
\]

For multi-output tasks it is:

\[
\left(\frac{1}{(2 \times n_{\text{samples}})}\right) \times \|Y - XW\|^\text{Fro}_2 \\
+ \alpha \times l1_{\text{ratio}} \times \|W\|_21 \\
+ 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times \|W\|^\text{Fro}_2
\]

Where:

\[
\|W\|_21 = \sqrt{\sum_i \sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

**Parameters**
X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, default=100] Number of alphas along the regularization path.

alphas [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coeff_init [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coeffs [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

**predict**(X)

Predict using the linear model.

**Parameters**

- X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- C [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \( ((y_{true} - y_{pred})^2).sum() \) and \( v \) is the total sum of squares \( ((y_{true} - y_{true.mean()})^2).sum() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- score [float] \( R^2 \) of self.predict(X) wrt. y.

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multiclass=’uniform_average’ from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params [dict] Estimator parameters.

**Returns**

**sklearn.linear_model.MultiTaskLasso**

```python
class sklearn.linear_model.MultiTaskLasso(**kwargs)
```

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_{21}
\]

Where:

||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}

i.e. the sum of norm of each row.

Read more in the User Guide.

**Parameters**

- **alpha** [float, default=1.0] Constant that multiplies the L1/L2 term. Defaults to 1.0.
- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **max_iter** [int, default=1000] The maximum number of iterations.
- **tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.
- **warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.
- **random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.
- **selection** [{‘cyclic’, ‘random’}, default=’cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4

**Attributes**

- **coef_** [ndarray of shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). Note that coef_ stores the transpose of W, W.T.
- **intercept_** [ndarray of shape (n_tasks,)] Independent term in decision function.
- **n_iter_** [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance.
- **dual_gap_** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
- **eps_** [float] The tolerance scaled scaled by the variance of the target y.
**sparse_coef_** [sparse matrix of shape (n_features,) or (n_tasks, n_features)] Sparse representation of the fitted coef_.

See also:

**MultiTaskLasso** Multi-task L1/L2 Lasso with built-in cross-validation.

**Lasso**

**MultiTaskElasticNet**

**Notes**

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X and y arguments of the fit method should be directly passed as Fortran-contiguous numpy arrays.

**Examples**

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskLasso(alpha=0.1)
>>> clf.fit([[0, 1], [1, 2], [2, 4]], [[0, 0], [1, 1], [2, 3]])
MultiTaskLasso(alpha=0.1)
>>> print(clf.coef_)
[[0. 0.60809415]
 [0. 0.94592424]]
>>> print(clf.intercept_)
[-0.41888636 -0.87382323]
```

**Methods**

- **fit**(X, y)  
  Fit MultiTaskElasticNet model with coordinate descent

- **get_params**(deep)  
  Get parameters for this estimator.

- **path**(args, **kwargs)  
  Compute elastic net path with coordinate descent.

- **predict**(X)  
  Predict using the linear model.

- **score**(X, y, sample_weight)  
  Return the coefficient of determination $R^2$ of the prediction.

- **set_params**(**params)  
  Set the parameters of this estimator.

**fit**(X, y)  
Fit MultiTaskElasticNet model with coordinate descent

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Data.
- **y** [ndarray of shape (n_samples, n_tasks)] Target. Will be cast to X’s dtype if necessary.
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically
convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

static path (*args, **kwargs)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{2 \times n\_samples} \times ||y - Xw||^2_2 \\
+ \alpha \times l1\_ratio \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
(\frac{1}{2 \times n\_samples}) \times ||Y - XW||^{Fro}_2 \\
+ \alpha \times l1\_ratio \times ||W||_21 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||^\text{Fro}_2
\]

Where:

\[
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) Training data. Pass directly
as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output
then X can be sparse.

y [array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs) Target val-
ues.

l1_ratio [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between
l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / 
alpha_max = 1e-3.

n_alphas [int, default=100] Number of alphas along the regularization path.

alphas [ndarray, default=None] List of alphas where to compute the models. If None alphas
are set automatically.
precompute | {'auto', bool or array-like of shape (n_features, n_features), default='auto']
Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy | [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-computed.

copy_X | [bool, default=True] If True, X will be copied; else, it may be overwritten.

coef_init | [ndarray of shape (n_features,), default=None] The initial values of the coefficients.

verbose | [bool or int, default=False] Amount of verbosity.

return_n_iter | [bool, default=False] Whether to return the number of iterations or not.

positive | [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input | [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params | [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas | [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coops | [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps | [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters | [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X)
Predict using the linear model.

Parameters

X | [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

**score** (*X*, *y*, **sample_weight**=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as

$$1 - \frac{u}{v}$$

where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean})^2).sum()$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

*X* [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

*y* [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for *X*.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

*score* [float] $R^2$ of self.predict (*X*) wrt *y*.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**property sparse_coef_**

Sparse representation of the fitted coef_.

**Examples using sklearn.linear_model.MultiTaskLasso**

- Joint feature selection with multi-task Lasso
Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for MultiTaskLasso is:

\[
\frac{1}{(2 \times n\_samples)} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_{21}
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

New in version 0.15.

Parameters

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.
- **n_alphas** [int, default=100] Number of alphas along the regularization path.
- **alphas** [array-like, default=None] List of alphas where to compute the models. If not provided, set automatically.
- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.
- **max_iter** [int, default=1000] The maximum number of iterations.
- **tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **cv** [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - int, to specify the number of folds.
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **verbose** [bool or int, default=False] Amount of verbosity.
**n_jobs** [int, default=None] Number of CPUs to use during the cross validation. Note that this is used only if multiple values for l1_ratio are given. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.

**selection** [{‘cyclic’, ‘random’}, default=’cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

**Attributes**

- **intercept_** [ndarray of shape (n_tasks,)] Independent term in decision function.
- **coef_** [ndarray of shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). Note that coef_ stores the transpose of W, W.T.
- **alpha_** [float] The amount of penalization chosen by cross validation.
- **mse_path_** [ndarray of shape (n_alphas, n_folds)] Mean square error for the test set on each fold, varying alpha.
- **alphas_** [ndarray of shape (n_alphas,)] The grid of alphas used for fitting.
- **n_iter_** [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.
- **dual_gap_** [float] The dual gap at the end of the optimization for the optimal alpha.

See also:

- MultiTaskElasticNet
- ElasticNetCV
- MultiTaskElasticNetCV

**Notes**

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X and y arguments of the fit method should be directly passed as Fortran-contiguous numpy arrays.

**Examples**

```python
>>> from sklearn.linear_model import MultiTaskLassoCV
>>> from sklearn.datasets import make_regression
>>> from sklearn.metrics import r2_score

>>> X, y = make_regression(n_targets=2, noise=4, random_state=0)
>>> reg = MultiTaskLassoCV(cv=5, random_state=0).fit(X, y)
>>> r2_score(y, reg.predict(X))
0.9994...
>>> reg.alpha_
0.5713...
```

**fit (X, y)**

Fit linear model with coordinate descent.

Fit is on grid of alphas and best alpha estimated by cross-validation.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path (*args, **kwargs)**

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n\_samples)} \times ||y - Xw||^2 + \alpha \times ||w||_1
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n\_samples)} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_{21}
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.
Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.
- **y** ([array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)) Target values
- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3
- **n_alphas** [int, default=100] Number of alphas along the regularization path
- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically
- **precompute** [‘auto’, bool or array-like of shape (n_features, n_features), default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.
- **Xy** [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-computed.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **coef_init** [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.
- **verbose** [bool or int, default=False] Amount of verbosity.
- **return_n_iter** [bool, default=False] whether to return the number of iterations or not.
- **positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).
- ****params [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

- **alphas** [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.
- **coefs** [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.
- **dual_gaps** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
- **n_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

- `lars_path`
- `Lasso`
- `LassoLars`
- `LassoCV`
- `LassoLarsCV`
- `sklearn.decomposition.sparse_encode`
Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a
Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In
particular, linear interpolation can be used to retrieve model coefficients between the values output by
lasso_path

Examples

Comparing lasso_path and lars_path with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0.          0.          0.46874778]
 [0.2159048   0.4425765  0.23689075]]

>>> # Now use lars_path and 1D linear interpolation to compute the
>>> # same path
>>> from sklearn.linear_model import lars_path
>>> from scipy import interpolate
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
                                               coef_path_lars[:, ::-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[0.          0.          0.46915237]
 [0.2159048   0.4425765  0.23668876]]
```

predict(X)

Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes
The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of $r2$ score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.22.6 Outlier-robust regressors

Any estimator using the Huber loss would also be robust to outliers, e.g. SGDRegressor with loss='huber'.

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linear_model.HuberRegressor(**kwargs)</td>
<td>Linear regression model that is robust to outliers.</td>
</tr>
<tr>
<td>linear_model.RANSACRegressor(**kwargs)</td>
<td>RANSAC (RANdom SAMple Consensus) algorithm.</td>
</tr>
</tbody>
</table>

sklearn.linear_model.HuberRegressor

class sklearn.linear_model.HuberRegressor(**kwargs)

Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where $|(y - X'w) / \sigma| < \epsilon$ and the absolute loss for the samples where $|(y - X'w) / \sigma| > \epsilon$, where $w$ and $\sigma$ are parameters to be optimized. The parameter $\sigma$ makes sure that if $y$ is scaled up or down by a certain factor, one does not need to rescale $\epsilon$ to achieve the same robustness. Note that this does not take into account the fact that the different features of $X$ may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the User Guide

New in version 0.18.

Parameters
epsilon [float, greater than 1.0, default=1.35] The parameter epsilon controls the number of samples that should be classified as outliers. The smaller the epsilon, the more robust it is to outliers.

max_iter [int, default=100] Maximum number of iterations that scipy.optimize.minimize(method="L-BFGS-B") should run for.

alpha [float, default=0.0001] Regularization parameter.

warm_start [bool, default=False] This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit. See the Glossary.

fit_intercept [bool, default=True] Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.

tol [float, default=1e-05] The iteration will stop when \( \max\{|\text{proj } g_i| : i = 1, \ldots, n\} \leq \text{tol} \) where \( g_i \) is the i-th component of the projected gradient.

Attributes

\( \text{coef} \) [array, shape (n_features,)] Features got by optimizing the Huber loss.

\( \text{intercept} \) [float] Bias.

\( \text{scale} \) [float] The value by which \( |y - X'w - c| \) is scaled down.

\( \text{n_iter} \) [int] Number of iterations that scipy.optimize.minimize(method="L-BFGS-B") has run for.

Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed max_iter. n_iter will now report at most max_iter.

\( \text{outliers} \) [array, shape (n_samples,)] A boolean mask which is set to True where the samples are identified as outliers.

References

</tbody>
</table>

### fit(X, y, sample_weight=None)

Fit the model according to the given training data.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [array-like, shape (n_samples,)] Target vector relative to X.
- **sample_weight** [array-like, shape (n_samples,)] Weight given to each sample.

**Returns**

- **self** [object]

### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

### predict (X)

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

### score (X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true}.mean())^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

7.22. **sklearn.linear_model**: Linear Models
Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.HuberRegressor

- HuberRegressor vs Ridge on dataset with strong outliers
- Robust linear estimator fitting

sklearn.linear_model.RANSACRegressor

class sklearn.linear_model.RANSACRegressor(**kwargs)

RANSAC (RANdom SAmple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set.

Read more in the User Guide.

Parameters

base_estimator [object, default=None] Base estimator object which implements the following methods:

- fit (X, y): Fit model to given training data and target values.
• **score**(*X*, *y*): Returns the mean accuracy on the given test data, which is used for the stop criterion defined by `stop_score`. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.

• **predict**(*X*): Returns predicted values using the linear model, which is used to compute residual error using loss function.

If `base_estimator` is `None`, then `LinearRegression` is used for target values of dtype `float`.

Note that the current implementation only supports regression estimators.

**min_samples** [int (>= 1) or float ([0, 1]), default=`None`] Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for `min_samples` >= 1, treated as a relative number `ceil(min_samples * X.shape[0])` for `min_samples` < 1. This is typically chosen as the minimal number of samples necessary to estimate the given `base_estimator`. By default a `sklearn.linear_model.LinearRegression()` estimator is assumed and `min_samples` is chosen as `X.shape[1] + 1`.

**residual_threshold** [float, default=`None`] Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values `y`.

**is_data_valid** [callable, default=`None`] This function is called with the randomly selected data before the model is fitted to it: `is_data_valid(X, y)`. If its return value is False the current randomly chosen sub-sample is skipped.

**is_model_valid** [callable, default=`None`] This function is called with the estimated model and the randomly selected data: `is_model_valid(model, X, y)`. If its return value is False the current randomly chosen sub-sample is skipped. Rejecting samples with this function is computationally costlier than with `is_data_valid`. `is_model_valid` should therefore only be used if the estimated model is needed for making the rejection decision.

**max_trials** [int, default=100] Maximum number of iterations for random sample selection.

**max_skips** [int, default=np.inf] Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by `is_data_valid` or invalid models defined by `is_model_valid`.

New in version 0.19.

**stop_n_inliers** [int, default=np.inf] Stop iteration if at least this number of inliers are found.

**stop_score** [float, default=np.inf] Stop iteration if score is greater equal than this threshold.

**stop_probability** [float in range [0, 1], default=0.99] RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least N samples (iterations):

\[
N \geq \log(1 - \text{probability}) / \log(1 - e^{m})
\]

where the probability (confidence) is typically set to high value such as 0.99 (the default) and e is the current fraction of inliers w.r.t. the total number of samples.

**loss** [string, callable, default=`'absolute_loss'`] String inputs, “absolute_loss” and “squared_loss” are supported which find the absolute loss and squared loss per sample respectively.
If `loss` is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the i-th value of the array corresponding to the loss on $X[i]$.

If the loss on a sample is greater than the `residual_threshold`, then this sample is classified as an outlier.

New in version 0.18.

**random_state** [int, RandomState instance, default=None] The generator used to initialize the centers. Pass an int for reproducible output across multiple function calls. See Glossary.

**Attributes**

- `estimator_` [object] Best fitted model (copy of the `base_estimator` object).
- `n_trials_` [int] Number of random selection trials until one of the stop criteria is met. It is always $\leq$ `max_trials`.
- `inlier_mask_` [bool array of shape [n_samples]] Boolean mask of inliers classified as True.
- `n_skips_no_inliers_` [int] Number of iterations skipped due to finding zero inliers.
  New in version 0.19.
- `n_skips_invalid_data_` [int] Number of iterations skipped due to invalid data defined by `is_data_valid`.
  New in version 0.19.
- `n_skips_invalid_model_` [int] Number of iterations skipped due to an invalid model defined by `is_model_valid`.
  New in version 0.19.

**fit (X, y, sample_weight=None)**

Fit estimator using RANSAC algorithm.

**Parameters**

- **X** [array-like or sparse matrix, shape [n_samples, n_features]] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Individual weights for each sample raises error if sample_weight is passed and base_estimator fit method does not support it.

New in version 0.18.

**Raises**

- **ValueError** If no valid consensus set could be found. This occurs if is_data_valid and is_model_valid return False for all max_trials randomly chosen sub-samples.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict (X)**

Predict using the estimated model.

This is a wrapper for estimator_.predict(X).

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]]

**Returns**

- **y** [array, shape = [n_samples] or [n_samples, n_targets]] Returns predicted values.

**score (X, y)**

Returns the score of the prediction.

This is a wrapper for estimator_.score(X, y).

**Parameters**

- **X** [numpy array or sparse matrix of shape [n_samples, n_features]] Training data.
- **y** [array, shape = [n_samples] or [n_samples, n_targets]] Target values.

**Returns**

- **score** [float] Score between 0.0 and 1.0 of the sample prediction. A higher score indicates a better fit.
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using `sklearn.linear_model.RANSACRegressor`

- Robust linear model estimation using RANSAC
- Theil-Sen Regression
- Robust linear estimator fitting

`sklearn.linear_model.TheilSenRegressor`

class `sklearn.linear_model.TheilSenRegressor`(**kwargs**)

Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size n_subsamples of the samples in X. Any value of n_subsamples between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is “n_samples choose n_subsamples”, it can be extremely large and can therefore be limited with max_subpopulation. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions. Read more in the User Guide.

**Parameters**

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **max_subpopulation** [int, default=1e4] Instead of computing with a set of cardinality ‘n choose k’, where n is the number of samples and k is the number of subamples (at least number of features), consider only a stochastic subpopulation of a given maximal size if ‘n choose k’ is larger than max_subpopulation. For other than small problem sizes this parameter will determine memory usage and runtime if n_subsamples is not changed.
- **n_subsamples** [int, default=None] Number of samples to calculate the parameters. This is at least the number of features (plus 1 if fit_intercept=True) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of subamples leading to maximal robustness. If n_subsamples is set to n_samples, Theil-Sen is identical to least squares.
- **max_iter** [int, default=300] Maximum number of iterations for the calculation of spatial median.
tol [float, default=1.e-3] Tolerance when calculating spatial median.

random_state [int, RandomState instance or None, default=None] A random number generator instance to define the state of the random permutations generator. Pass an int for reproducible output across multiple function calls. See Glossary

n_jobs [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [bool, default=False] Verbose mode when fitting the model.

Attributes

coef_ [ndarray of shape (n_features,)] Coefficients of the regression model (median of distribution).

intercept_ [float] Estimated intercept of regression model.

breakdown_ [float] Approximated breakdown point.

n_iter_ [int] Number of iterations needed for the spatial median.

n_subpopulation_ [int] Number of combinations taken into account from ‘n choose k’, where n is the number of samples and k is the number of subsamples.

References

Examples

```python
>>> from sklearn.linear_model import TheilSenRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(...
    n_samples=200, n_features=2, noise=4.0, random_state=0)

>>> reg = TheilSenRegressor(random_state=0).fit(X, y)

>>> reg.score(X, y)
0.9884...

>>> reg.predict(X[:1,])
array([-31.5871...])
```

Methods

```
+ fit(X, y) Fit linear model.
+ get_params([deep]) Get parameters for this estimator.
+ predict(X) Predict using the linear model.
+ score(X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.
+ set_params(**params) Set the parameters of this estimator.
```

`fit (X, y)`
Fit linear model.

Parameters
X [ndarray of shape (n_samples, n_features)] Training data.

y [ndarray of shape (n_samples,)] Target values.

Returns
self [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

predict (X)
Predict using the linear model.

Parameters
X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using `sklearn.linear_model.TheilSenRegressor`

- *Theil-Sen Regression*
- *Robust linear estimator fitting*

### 7.22.7 Generalized linear models (GLM) for regression

These models allow for response variables to have error distributions other than a normal distribution:

- `linear_model.PoissonRegressor(*[, alpha, ...])`
  Generalized Linear Model with a Poisson distribution.
- `linear_model.TweedieRegressor(*[, power, ...])`
  Generalized Linear Model with a Tweedie distribution.
- `linear_model.GammaRegressor(*[, alpha, ...])`
  Generalized Linear Model with a Gamma distribution.

**sklearn.linear_model.PoissonRegressor**

```python
class sklearn.linear_model.PoissonRegressor(*, alpha=1.0, fit_intercept=True,
            max_iter=100, tol=0.0001,
            warm_start=False, verbose=0)
```

Generalized Linear Model with a Poisson distribution.

Read more in the *User Guide*.

New in version 0.23.

**Parameters**

- **alpha** [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. $alpha = 0$ is equivalent to unpenalized GLMs. In this case, the design matrix $X$ must have full column rank (no collinearities).
- **fit_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor ($X @ \text{coef} + \text{intercept}$).
max_iter  [int, default=100] The maximal number of iterations for the solver.

tol  [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when
max{|g_j|, j = 1, ..., d} <= tol where g_j is the j-th component of the
gradient (derivative) of the objective function.

warm_start  [bool, default=False] If set to True, reuse the solution of the previous call to fit
as initialization for coef_ and intercept_.

verbose  [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

Attributes

coef_  [array of shape (n_features,)] Estimated coefficients for the linear predictor (X @ coef_ + intercept_) in the GLM.

intercept_  [float] Intercept (a.k.a. bias) added to linear predictor.

n_iter_  [int] Actual number of iterations used in the solver.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.PoissonRegressor()
>>> X = [[1, 2], [2, 3], [3, 4], [4, 3]]
>>> y = [12, 17, 22, 21]
>>> clf.fit(X, y)
PoissonRegressor()
>>> clf.score(X, y)
0.990...
>>> clf.coef_
anarray([0.121..., 0.158...])
>>> clf.intercept_
2.088...
>>> clf.predict([[1, 1], [3, 4]])
anarray([10.676..., 21.875...])
```

```python
fit (X, y, sample_weight=None)
   Fit a Generalized Linear Model.
```

Parameters

- `X` [:array-like, sparse matrix] of shape (n_samples, n_features)] Training data.
- `y` [array-like of shape (n_samples,)] Target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Returns
self [returns an instance of self.]

def get_params(deep=True):
    Get parameters for this estimator.

    Parameters
    
    deep [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

    Returns

    params [dict] Parameter names mapped to their values.

def predict(X):
    Predict using GLM with feature matrix X.

    Parameters

    X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

    Returns

    y_pred [array of shape (n_samples,)] Returns predicted values.

def score(X, y, sample_weight=None):
    Compute $D^2$, the percentage of deviance explained.

    $D^2$ is a generalization of the coefficient of determination $R^2$. $R^2$ uses squared error and $D^2$ deviance.
    Note that those two are equal for family='normal'.

    $D^2$ is defined as $D^2 = 1 - \frac{D(y_{true}, y_{pred})}{D_{null}}$, $D_{null}$ is the null deviance, i.e. the deviance of a model with
    intercept alone, which corresponds to $y_{pred} = \bar{y}$. The mean $\bar{y}$ is averaged by sample_weight. Best possible
    score is 1.0 and it can be negative (because the model can be arbitrarily worse).

    Parameters

    X [{array-like, sparse matrix} of shape (n_samples, n_features)] Test samples.

    y [array-like of shape (n_samples,)] True values of target.

    sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

    Returns

    score [float] $D^2$ of self.predict(X) w.r.t. y.

def set_params(**params):
    Set the parameters of this estimator.

    The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
    parameters of the form <component>__<parameter> so that it's possible to update each component
    of a nested object.

    Parameters

    **params [dict] Estimator parameters.

    Returns

    self [estimator instance] Estimator instance.
Examples using `sklearn.linear_model.PoissonRegressor`

- Release Highlights for scikit-learn 0.23
- Poisson regression and non-normal loss
- Tweedie regression on insurance claims

`sklearn.linear_model.TweedieRegressor`

class `sklearn.linear_model.TweedieRegressor`(*, power=0.0, alpha=1.0, fit_intercept=True, link='auto', max_iter=100, tol=0.0001, warm_start=False, verbose=0)

Generalized Linear Model with a Tweedie distribution.

This estimator can be used to model different GLMs depending on the `power` parameter, which determines the underlying distribution.

Read more in the *User Guide*.

New in version 0.23.

**Parameters**

- `power` [float, default=0] The power determines the underlying target distribution according to the following table:

<table>
<thead>
<tr>
<th>Power</th>
<th>Distribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal</td>
</tr>
<tr>
<td>1</td>
<td>Poisson</td>
</tr>
<tr>
<td>(1,2)</td>
<td>Compound Poisson Gamma</td>
</tr>
<tr>
<td>2</td>
<td>Gamma</td>
</tr>
<tr>
<td>3</td>
<td>Inverse Gaussian</td>
</tr>
</tbody>
</table>

For $0 < \text{power} < 1$, no distribution exists.

- `alpha` [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. $\alpha = 0$ is equivalent to unpenalized GLMs. In this case, the design matrix $X$ must have full column rank (no collinearities).

- `link` [‘auto’, ‘identity’, ‘log’], default=‘auto’ The link function of the GLM, i.e. mapping from linear predictor $X @ \text{coeff} + \text{intercept}$ to prediction $y_{\text{pred}}$. Option ‘auto’ sets the link depending on the chosen family as follows:
  - ‘identity’ for Normal distribution
  - ‘log’ for Poisson, Gamma and Inverse Gaussian distributions

- `fit_intercept` [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor ($X @ \text{coef} + \text{intercept}$).

- `max_iter` [int, default=100] The maximal number of iterations for the solver.

- `tol` [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when $\max\{|g_j|, j = 1, \ldots, d\} \leq \text{tol}$ where $g_j$ is the $j$-th component of the gradient (derivative) of the objective function.

- `warm_start` [bool, default=False] If set to True, reuse the solution of the previous call to fit as initialization for coef_ and intercept_.

2268 Chapter 7. API Reference
verbose [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

Attributes

coef_ [array of shape (n_features,)] Estimated coefficients for the linear predictor ($X \cdot \text{coef}_\text{+ intercept}_$) in the GLM.

intercept_ [float] Intercept (a.k.a. bias) added to linear predictor.

n_iter_ [int] Actual number of iterations used in the solver.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.TweedieRegressor()
>>> X = [[1, 2], [2, 3], [3, 4], [4, 3]]
>>> y = [2, 3.5, 5, 5.5]
>>> clf.fit(X, y)
TweedieRegressor()
>>> clf.score(X, y)
0.839...
>>> clf.coef_
array([0.599..., 0.299...])
>>> clf.intercept_
1.600...
>>> clf.predict([[1, 1], [3, 4]])
array([2.500..., 4.599...])
```

**fit** (X, y, sample_weight=\text{None})

Fit a Generalized Linear Model.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=\text{None}] Sample weights.

Returns

- **self** [returns an instance of self.]

**get_params** (deep=\text{True})

Get parameters for this estimator.

Parameters

- **deep** [bool, default=\text{True}] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params  [dict] Parameter names mapped to their values.

predict (X)
Predict using GLM with feature matrix X.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

Returns

y_pred  [array of shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Compute D^2, the percentage of deviance explained.

D^2 is a generalization of the coefficient of determination R^2. R^2 uses squared error and D^2 deviance. Note that those two are equal for family='normal'.

D^2 is defined as \( D^2 = 1 - \frac{D(y_{true}, y_{pred})}{D_{null}} \), \( D_{null} \) is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to \( y_{pred} = \bar{y} \). The mean \( \bar{y} \) is averaged by sample_weight. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Test samples.

y  [array-like of shape (n_samples,)] True values of target.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] D^2 of self.predict(X) w.r.t. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<component>__<parameter>\) so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

Examples using sklearn.linear_model.TweedieRegressor

- Release Highlights for scikit-learn 0.23
- Tweedie regression on insurance claims
sklearn.linear_model.GammaRegressor

class sklearn.linear_model.GammaRegressor(*, alpha=1.0, fit_intercept=True, max_iter=100, tol=0.0001, warm_start=False, verbose=0)

Generalized Linear Model with a Gamma distribution.

Read more in the User Guide.

New in version 0.23.

Parameters

alpha [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. alpha = 0 is equivalent to unpenalized GLMs. In this case, the design matrix X must have full column rank (no collinearities).

fit_intercept [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor (X @ coef + intercept).

max_iter [int, default=100] The maximal number of iterations for the solver.

tol [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when max(|g_j|, j = 1, ..., d) <= tol where g_j is the j-th component of the gradient (derivative) of the objective function.

warm_start [bool, default=False] If set to True, reuse the solution of the previous call to fit as initialization for coef_ and intercept_.

verbose [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

Attributes

coef_ [array of shape (n_features,)] Estimated coefficients for the linear predictor (X * coef_ + intercept_) in the GLM.

intercept_ [float] Intercept (a.k.a. bias) added to linear predictor.

n_iter_ [int] Actual number of iterations used in the solver.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.GammaRegressor()
>>> X = [[1, 2], [2, 3], [3, 4], [4, 3]]
>>> y = [19, 26, 33, 30]
>>> clf.fit(X, y)
GammaRegressor()
>>> clf.score(X, y)
0.773...
>>> clf.coef_
array([[0.072..., 0.066...]])
>>> clf.intercept_
2.896...
>>> clf.predict([[1, 0], [2, 8]])
array([[19.483..., 35.795...]])
```

`fit (X, y, sample_weight=None)`
Fit a Generalized Linear Model.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **self** [returns an instance of self.]

`get_params (deep=True)`
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

`predict (X)`
Predict using GLM with feature matrix X.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] Samples.

Returns

- **y_pred** [array of shape (n_samples,)] Returns predicted values.

`score (X, y, sample_weight=None)`
Compute $D^2$, the percentage of deviance explained.

$D^2$ is a generalization of the coefficient of determination $R^2$. $R^2$ uses squared error and $D^2$ deviance. Note that those two are equal for family='normal'.

$D^2$ is defined as $D^2 = 1 - \frac{D_{\text{null}}}{D_{\text{null}}}$. $D_{\text{null}}$ is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to $y_{\text{pred}} = \bar{y}$. The mean $\bar{y}$ is averaged by sample_weight. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,)] True values of target.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score  [float] $D^2$ of self.predict(X) w.r.t. y.

set_params (**params)
   Set the parameters of this estimator.

   The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

   Parameters

   **params  [dict] Estimator parameters.

   Returns

   self  [estimator instance] Estimator instance.

Examples using sklearn.linear_model.GammaRegressor

• Release Highlights for scikit-learn 0.23
• Tweedie regression on insurance claims

7.22.8 Miscellaneous

sklearn.linear_model.GammaRegressor

sklearn.linear_model.GammaRegressor(C=1.0, fit_intercept=True, max_iter=1000, tol=0.001, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, shuffle=True, verbose=0, loss='epsilon_insensitive', epsilon=0.1, random_state=None, warm_start=False, average=False)

Passive Aggressive Regressor

Read more in the User Guide.

Parameters
C [float, default=1.0] Maximum step size (regularization). Defaults to 1.0.

**fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

**max_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

    New in version 0.19.

tol [float or None, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

    New in version 0.19.

**early_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

    New in version 0.20.

**validation_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

    New in version 0.20.

**n_iter_no_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

    New in version 0.20.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, default=0] The verbosity level

**loss** [string, default=”epsilon_insensitive”] The loss function to be used: epsilon_insensitive: equivalent to PA-I in the reference paper. squared_epsilon_insensitive: equivalent to PA-II in the reference paper.

**epsilon** [float, default=DEFAULT_EPSILON] If the difference between the current prediction and the correct label is below this threshold, the model is not updated.

**random_state** [int, RandomState instance, default=None] Used to shuffle the training data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

**average** [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

    New in version 0.19: parameter average to use weights averaging in SGD

Attributes
coef_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion.

t_ [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

sklearn.linear_model.enet_path

sklearn.linear_model.enet_path(X, y, *, ll_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times \|y - Xw\|^2_2 \\
+ \alpha \times ll_{\text{ratio}} \times \|w\|^2_2 \\
+ 0.5 \times \alpha \times (1 - ll_{\text{ratio}}) \times \|w\|_1
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}} \times \text{number of outputs})} \times \sum_{i=1}^{\text{number of outputs}} \|y_i - Xw_i\|^2_2 \\
+ \alpha \times ll_{\text{ratio}} \times \sum_{i=1}^{\text{number of outputs}} \|w_i\|^2_2 \\
+ 0.5 \times \alpha \times (1 - ll_{\text{ratio}}) \times \sum_{i=1}^{\text{number of outputs}} \|w_i\|_1
\]
\[
\frac{1}{2 + n_{\text{samples}}} \cdot ||Y - XW||^2_{\text{Fro}} + \alpha \cdot l1_{\text{ratio}} \cdot ||W||_{2,1} + 0.5 \cdot \alpha \cdot (1 - l1_{\text{ratio}}) \cdot ||W||^2_{\text{Fro}}
\]

Where:

\[||W||_{2,1} = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If \(y\) is mono-output then \(X\) can be sparse.

- **y** ([array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)) Target values.

- **l1_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). \(l1_{\text{ratio}}=1\) corresponds to the Lasso.

- **eps** [float, default=1e-3] Length of the path. \(\text{eps}=1e^{-3}\) means that \(\alpha_{\text{min}} / \alpha_{\text{max}} = 1e^{-3}\).

- **n_alphas** [int, default=100] Number of alphas along the regularization path.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **Xy** [array-like of shape (n_features,) or (n_features, n_outputs), default=None] \(Xy = \text{np.dot}(X.T, y)\) that can be precomputed. It is useful only when the Gram matrix is precomputed.

- **copy_X** [bool, default=True] If True, \(X\) will be copied; else, it may be overwritten.

- **coef_init** [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.

- **verbose** [bool or int, default=False] Amount of verbosity.

- **return_n_iter** [bool, default=False] Whether to return the number of iterations or not.

- **positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when \(y\).ndim == 1).

- **check_input** [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params** [kwargs] Keyword arguments passed to the coordinate descent solver.

**Returns**

- **alphas** [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

- **coefs** [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

- **dual_gaps** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
**n_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

- `ElasticNetCV`

**Notes**

For an example, see `examples/linear_model/plot_lasso_coordinate_descent_path.py`.

Examples using `sklearn.linear_model.enet_path`

- Lasso and Elastic Net

`sklearn.linear_model.lars_path`

`sklearn.linear_model.lars_path(X, y=None, Xy=None, Gram=None, max_iter=500, alpha_min=0, method='lar', copy_X=True, eps=2.220446049250313e-16, copy_Gram=True, verbose=0, return_path=True, return_n_iter=False, positive=False)`

Compute Least Angle Regression or Lasso path using LARS algorithm [1] The optimization objective for the case method='lasso' is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

in the case of method='lars', the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the User Guide.

**Parameters**

- **X** [None or array-like of shape (n_samples, n_features)] Input data. Note that if X is None then the Gram matrix must be specified, i.e., cannot be None or False.
- **y** [None or array-like of shape (n_samples,)] Input targets.
- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- **Gram** [None, 'auto', array-like of shape (n_features, n_features), default=None] Precomputed Gram matrix (X' * X), if 'auto', the Gram matrix is precomputed from the given X, if there are more samples than features.
- **max_iter** [int, default=500] Maximum number of iterations to perform, set to infinity for no limit.
- **alpha_min** [float, default=0] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.

copy_X [bool, default=True] If False, X is overwritten.

eps [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

copy_Gram [bool, default=True] If False, Gram is overwritten.

verbose [int, default=0] Controls output verbosity.

return_path [bool, default=True] If return_path==True returns the entire path, else returns only the last point of the path.

return_n_iter [bool, default=False] Whether to return the number of iterations.

positive [bool, default=False] Restrict coefficients to be >= 0. This option is only allowed with method ‘lasso’. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.

Returns

alphas [array-like of shape (n_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.

active [array-like of shape (n_alphas,)] Indices of active variables at the end of the path.

coops [array-like of shape (n_features, n_alphas + 1)] Coefficients along the path

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

LarsCV
sklearn.decomposition.sparse_encode
Examples using `sklearn.linear_model.lars_path`:

- Lasso path using LARS

```python
sklearn.linear_model.lars_path_gram(Xy, Gram, *, n_samples, max_iter=500, alpha_min=0, method='lar', copy_X=True, eps=2.220446049250313e-16, copy_Gram=True, verbose=0, return_path=True, return_n_iter=False, positive=False)
```

`lars_path` in the sufficient stats mode [1]

The optimization objective for the case method='lasso' is:

\[
\frac{1}{2n} \| y - Xw \|_2^2 + \alpha \| w \|_1
\]

in the case of method='lar', the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the User Guide.

**Parameters**

- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets)] Xy = np.dot(X.T, y).
- **Gram** [array-like of shape (n_features, n_features)] Gram = np.dot(X.T * X).
- **n_samples** [int or float] Equivalent size of sample.
- **max_iter** [int, default=500] Maximum number of iterations to perform, set to infinity for no limit.
- **alpha_min** [float, default=0] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.
- **method** [{'lar', 'lasso'}, default='lar'] Specifies the returned model. Select 'lar' for Least Angle Regression, 'lasso' for the Lasso.
- **copy_X** [bool, default=True] If False, X is overwritten.
- **eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.
- **copy_Gram** [bool, default=True] If False, Gram is overwritten.
- **verbose** [int, default=0] Controls output verbosity.
- **return_path** [bool, default=True] If return_path==True returns the entire path, else returns only the last point of the path.
- **return_n_iter** [bool, default=False] Whether to return the number of iterations.
- **positive** [bool, default=False] Restrict coefficients to be >= 0. This option is only allowed with method 'lasso'. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha
value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.

Returns

- **alphas** [array-like of shape (n_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.
- **active** [array-like of shape (n_alphas,)] Indices of active variables at the end of the path.
- **coefs** [array-like of shape (n_features, n_alphas + 1)] Coefficients along the path
- **n_iter** [int] Number of iterations run. Returned only if return_n_iter is set to True.

sklearn.linear_model.lasso_path

sklearn.linear_model.**lasso_path**(X, y, *, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, **params)

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^2_Fro + alpha * ||W||_21
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the User Guide.
Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)] Target values

eps [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3

n_alphas [int, default=100] Number of alphas along the regularization path

alphas [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically

precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coef_init [ndarray of shape (n_features,), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

**params [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coops [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

lars_path
Lasso
LassoLars
LassoCV
LassoLarsCV
sklearn.decomposition.sparse_encode
Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by lars_path

Examples

Comparing lasso_path and lars_path with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0. 0. 0.46874778]
 [0.2159048 0.4425765 0.23689075]]

>>> # Now use lars_path and 1D linear interpolation to compute the same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
... coef_path_lars[:, ::-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[0. 0. 0.46915237]
 [0.2159048 0.4425765 0.23668876]]
```

Examples using sklearn.linear_model.lasso_path

- Lasso and Elastic Net

sklearn.linear_model.orthogonal_mp

sklearn.linear_model.orthogonal_mp(X, y, *, n_nonzero_coefs=None, tol=None, precompute=False, copy_X=True, return_path=False, return_n_iter=False)

Orthogonal Matching Pursuit (OMP).

Solves n_targets Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using n_nonzero_coefs: argmin ||y - Xgamma||^2 subject to ||gamma||_0 <= n_{nonzero coefs}

When parametrized by error using the parameter tol: argmin ||gamma||_0 subject to ||y - Xgamma||^2 <= tol

Read more in the User Guide.

Parameters

- X [ndarray of shape (n_samples, n_features)] Input data. Columns are assumed to have unit norm.
y [ndarray of shape (n_samples,) or (n_samples, n_targets)] Input targets.

n_nonzero_coefs [int, default=None] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol [float, default=None] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

precompute ['auto' or bool, default=False] Whether to perform precomputations. Improves performance when n_targets or n_samples is very large.

copy_X [bool, default=True] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.

return_path [bool, default=False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

Returns

coef [ndarray of shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If return_path=True, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.

n_iters [array-like or int] Number of active features across every target. Returned only if return_n_iter is set to True.

OrthogonalMatchingPursuit

orthogonal_mp_gram

lars_path

sklearn.decomposition.sparse_encode

Notes

sklearn.linear_model.orthogonal_mp_gram

sklearn.linear_model.orthogonal_mp_gram(Gram, Xy, *, n_nonzero_coefs=None, tol=None, norms_squared=None, copy_Gram=True, copy_Xy=True, return_path=False, return_n_iter=False)

Gram Orthogonal Matching Pursuit (OMP).

Solves n_targets Orthogonal Matching Pursuit problems using only the Gram matrix X.T * X and the product X.T * y.

Read more in the User Guide.
Parameters

- **Gram** [ndarray of shape (n_features, n_features)] Gram matrix of the input data: $X^T \times X$.
- **Xy** [ndarray of shape (n_features,) or (n_features, n_targets)] Input targets multiplied by $X$: $X^T \times y$.
- **n_nonzero_coefs** [int, default=None] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
- **tol** [float, default=None] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.
- **norms_squared** [array-like of shape (n_targets,), default=None] Squared L2 norms of the lines of y. Required if tol is not None.
- **copy_Gram** [bool, default=True] Whether the gram matrix must be copied by the algorithm. A false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.
- **copy_Xy** [bool, default=True] Whether the covariance vector Xy must be copied by the algorithm. If False, it may be overwritten.
- **return_path** [bool, default=False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
- **return_n_iter** [bool, default=False] Whether or not to return the number of iterations.

Returns

- **coef** [ndarray of shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If return_path=True, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.
- **n_iters** [array-like or int] Number of active features across every target. Returned only if return_n_iter is set to True.

Notes

sklearn.linear_model.ridge_regression

sklearn.linear_model.ridge_regression(X, y, alpha, *, sample_weight=None, solver='auto',
max_iter=None, tol=0.001, verbose=0, random_state=None, return_n_iter=False, return_intercept=False, check_input=True)

Solve the ridge equation by the method of normal equations.

Read more in the User Guide.

Parameters

X  [{ndarray, sparse matrix, LinearOperator} of shape (n_samples, n_features)] Training data
y  [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values
alpha  [float or array-like of shape (n_targets,)] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to 1 / (2C) in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.
sample_weight  [float or array-like of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight. If sample_weight is not None and solver='auto', the solver will be set to ‘cholesky’.
max_iter  [int, default=None] Maximum number of iterations for conjugate gradient solver. For the ‘sparse_cg’ and ‘lsqr’ solvers, the default value is determined by scipy.sparse.linalg. For ‘sag’ and saga solver, the default value is 1000.

New in version 0.17: Stochastic Average Gradient descent solver.
New in version 0.19: SAGA solver.
tol [float, default=1e-3] Precision of the solution.

verbose [int, default=0] Verbosity level. Setting verbose > 0 will display additional information depending on the solver used.

random_state [int, RandomState instance, default=None] Used when solver == ‘sag’ or ‘saga’ to shuffle the data. See Glossary for details.

return_n_iter [bool, default=False] If True, the method also returns n_iter, the actual number of iteration performed by the solver.

New in version 0.17.

return_intercept [bool, default=False] If True and if X is sparse, the method also returns the intercept, and the solver is automatically changed to ‘sag’. This is only a temporary fix for fitting the intercept with sparse data. For dense data, use sklearn.linear_model._preprocess_data before your regression.

New in version 0.17.

check_input [bool, default=True] If False, the input arrays X and y will not be checked.

New in version 0.21.

Returns

coeff [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

n_iter [int, optional] The actual number of iteration performed by the solver. Only returned if return_n_iter is True.

intercept [float or ndarray of shape (n_targets,)] The intercept of the model. Only returned if return_intercept is True and if X is a scipy sparse array.

Notes

This function won’t compute the intercept.

7.23 sklearn.manifold: Manifold Learning

The sklearn.manifold module implements data embedding techniques.

<td>t-distributed Stochastic Neighbor Embedding</td>
</tr>
</tbody>
</table>
7.23.1 sklearn.manifold.Isomap

class sklearn.manifold.Isomap(**kwargs)

Isomap Embedding

Non-linear dimensionality reduction through Isometric Mapping

Read more in the User Guide.

Parameters

n_neighbors [int, default=5] number of neighbors to consider for each point.
n_components [int, default=2] number of coordinates for the manifold
eigen_solver [{‘auto’, ‘arpack’, ‘dense’}, default=’auto’] ‘auto’ : Attempt to choose the most efficient solver for the given problem.
‘arpack’ : Use Arnoldi decomposition to find the eigenvalues and eigenvectors.
‘dense’ : Use a direct solver (i.e. LAPACK) for the eigenvalue decomposition.
tol [float, default=0] Convergence tolerance passed to arpack or lobpcg. not used if eigen_solver == ‘dense’.
max_iter [int, default=None] Maximum number of iterations for the arpack solver. not used if eigen_solver == ‘dense’.
‘auto’ : attempt to choose the best algorithm automatically.
‘FW’ : Floyd-Warshall algorithm.
‘D’ : Dijkstra’s algorithm.
n_jobs [int or None, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
metric [string, or callable, default=”minkowski”] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by sklearn.metrics.pairwise_distances for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a Glossary.

New in version 0.22.
p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

New in version 0.22.
metric_params [dict, default=None] Additional keyword arguments for the metric function.

Attributes

embedding_ [array-like, shape (n_samples, n_components)] Stores the embedding vectors.
**KernelPCA** object used to implement the embedding.

**nbrs_** [sklearn.neighbors.NearestNeighbors instance] Stores nearest neighbors instance, including BallTree or KDtree if applicable.

**dist_matrix_** [array-like, shape (n_samples, n_samples)] Stores the geodesic distance matrix of training data.

**References**

[1]

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import Isomap
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = Isomap(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

**fit**(X, y=None)

Compute the embedding vectors for data X

**Parameters**

- **X** [[array-like, sparse graph, BallTree, KDTree, NearestNeighbors]] Sample data, shape = (n_samples, n_features), in the form of a numpy array, sparse graph, precomputed tree, or NearestNeighbors object.
- **y** [Ignored]

**Returns**

- **self** [returns an instance of self.]

**fit_transform**(X, y=None)

Fit the model from data in X and transform X.

**Parameters**

- **X** [[array-like, sparse graph, BallTree, KDTree]] Training vector, where n_samples is the number of samples and n_features is the number of features.
Returns

X_new [array-like, shape (n_samples, n_components)]

get_params (deep=True)
Get parameters for this estimator.

Parameters

dee [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

reconstruction_error ()
Compute the reconstruction error for the embedding.

Returns

reconstruction_error [float]

Notes

The cost function of an isomap embedding is

\[
E = \frac{\text{frobenius_norm}[K(D) - K(D_{\text{fit})}]}{n_{\text{samples}}}
\]

Where D is the matrix of distances for the input data X, D_{\text{fit}} is the matrix of distances for the output
embedding X_{\text{fit}}, and K is the isomap kernel:

\[
K(D) = -0.5 \times (I - 1/n_{\text{samples}}) \times D^2 \times (I - 1/n_{\text{samples}})
\]

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Transform X.

This is implemented by linking the points X into the graph of geodesic distances of the training data.
First the n_neighbors nearest neighbors of X are found in the training data, and from these the shortest
geodesic distances from each point in X to each point in the training data are computed in order to construct
the kernel. The embedding of X is the projection of this kernel onto the embedding vectors of the training
set.

Parameters

X [array-like, shape (n_queries, n_features)] If neighbors_algorithm='precomputed', X is
assumed to be a distance matrix or a sparse graph of shape (n_queries, n_samples_fit).
Returns

\[ \text{X}_\text{new} \] [array-like, shape (n_queries, n_components)]

7.23.2 `sklearn.manifold.LocallyLinearEmbedding`

class `sklearn.manifold.LocallyLinearEmbedding(**kwargs)`

Locally Linear Embedding

Read more in the User Guide.

Parameters

- **n_neighbors** [int, default=5] number of neighbors to consider for each point.
- **n_components** [int, default=2] number of coordinates for the manifold
- **reg** [float, default=1e-3] regularization constant, multiplies the trace of the local covariance matrix of the distances.
- **eigen_solver** ['auto', 'arpack', 'dense'], default='auto' auto : algorithm will attempt to choose the best method for input data
- **tol** [float, default=1e-6] Tolerance for ‘arpack’ method Not used if eigen_solver='dense'.
- **max_iter** [int, default=100] maximum number of iterations for the arpack solver. Not used if eigen_solver='dense'.
- **method** ['standard', 'hessian', 'modified', 'ltsa'], default='standard'
- **hessian_tol** [float, default=1e-4] Tolerance for Hessian eigenmapping method. Only used if method = 'hessian'
- **modified_tol** [float, default=1e-12] Tolerance for modified LLE method. Only used if method = 'modified'
neighbors_algorithm  [['auto', 'brute', 'kd_tree', 'ball_tree'], default='auto'] algorithm to use
for nearest neighbors search, passed to neighbors.NearestNeighbors instance

n_jobs  [int or None, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

embedding_  [array-like, shape [n_samples, n_components]] Stores the embedding vectors

reconstruction_error_  [float] Reconstruction error associated with embedding_

nbrs_  [NearestNeighbors object] Stores nearest neighbors instance, including BallTree or KDtree if applicable.

```python
>>> fit (X, y=None)
Compute the embedding vectors for data X

Parameters

X  [array-like of shape [n_samples, n_features]] training set.

y  [Ignored]

Returns
```
**self** [returns an instance of self.]

**fit_transform** *(X, y=None)*

Compute the embedding vectors for data X and transform X.

**Parameters**

X [array-like of shape [n_samples, n_features]] training set.

y [Ignored]

**Returns**

X_new [array-like, shape (n_samples, n_components)]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as **Pipeline**). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** *(X)*

Transform new points into embedding space.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

X_new [array, shape = [n_samples, n_components]]

**Notes**

Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

### 7.23.3 `sklearn.manifold.MDS`

**class sklearn.manifold.MDS(**kwargs)**

Multidimensional scaling.

Read more in the User Guide.

**Parameters**

- `n_components` [int, default=2] Number of dimensions in which to immerse the dissimilarities.
- `metric` [bool, default=True] If True, perform metric MDS; otherwise, perform nonmetric MDS.
- `n_init` [int, default=4] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.
- `max_iter` [int, default=300] Maximum number of iterations of the SMACOF algorithm for a single run.
- `verbose` [int, default=0] Level of verbosity.
- `eps` [float, default=1e-3] Relative tolerance with respect to stress at which to declare convergence.
- `n_jobs` [int, default=None] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel.
  - None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- `random_state` [int, RandomState instance or None, default=None] Determines the random number generator used to initialize the centers. Pass an int for reproducible results across multiple function calls. See Glossary for more details.
- `dissimilarity` [‘euclidean’, ‘precomputed’], default='euclidean'] Dissimilarity measure to use:
  - ‘euclidean’: Pairwise Euclidean distances between points in the dataset.
  - ‘precomputed’: Pre-computed dissimilarities are passed directly to fit and fit_transform.

**Attributes**

- `embedding_` [ndarray of shape (n_samples, n_components)] Stores the position of the dataset in the embedding space.
- `stress_` [float] The final value of the stress (sum of squared distances of the disparities and the distances for all constrained points).
- `dissimilarity_matrix_` [ndarray of shape (n_samples, n_samples)] Pairwise dissimilarities between the points. Symmetric matrix that:
• either uses a custom dissimilarity matrix by setting `dissimilarity` to ‘precomputed’;
• or constructs a dissimilarity matrix from data using Euclidean distances.

```
n_iter_ [int] The number of iterations corresponding to the best stress.
```

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import MDS

>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = MDS(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

Methods

```
fit(X[, y, init])
fit_transform(X[, y, init])
get_params([deep])
set_params(**params)
```

```
fit (X, y=None, init=None)
Computes the position of the points in the embedding space.

Parameters

X [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

y [Ignored]

init [ndarray of shape (n_samples,), default=None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

fit_transform (X, y=None, init=None)
Fit the data from X, and returns the embedded coordinates.
```

Parameters

2294 Chapter 7. API Reference
X [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Input data. If dissimilarity=='precomputed', the input should be the dissimilarity matrix.

y [Ignored]

init [ndarray of shape (n_samples,), default=None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.23.4 sklearn.manifold.SpectralEmbedding

class sklearn.manifold.SpectralEmbedding(**kwargs)
Spectral embedding for non-linear dimensionality reduction.

Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.

Note: Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the User Guide.

Parameters

n_components [int, default=2] The dimension of the projected subspace.
affinity [‘nearest_neighbors’, ‘rbf’, ‘precomputed’, ‘precomputed_nearest_neighbors’] or callable, default=’nearest_neighbors’]

How to construct the affinity matrix.

• ‘nearest_neighbors’ : construct the affinity matrix by computing a graph of nearest neighbors.
• ‘rbf’ : construct the affinity matrix by computing a radial basis function (RBF) kernel.
• ‘precomputed’ : interpret $X$ as a precomputed affinity matrix.
• ‘precomputed_nearest_neighbors’ : interpret $X$ as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the $n_neighbors$ nearest neighbors.
• callable : use passed in function as affinity the function takes in data matrix (n_samples, n_features) and return affinity matrix (n_samples, n_samples).

gamma [float, default=None] Kernel coefficient for rbf kernel. If None, gamma will be set to $1/n_features$.

random_state [int, RandomState instance or None, default=None] Determines the random number generator used for the initialization of the lobpcg eigenvectors when solver == ‘amg’. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

eigen_solver [‘arpack’, ‘lobpcg’, ‘amg’], default=None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems. If None, then 'arpack' is used.

n_neighbors [int, default=None] Number of nearest neighbors for nearest_neighbors graph building. If None, n_neighbors will be set to max(n_samples/10, 1).

n_jobs [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

embedding_ [ndarray of shape (n_samples, n_components)] Spectral embedding of the training matrix.

affinity_matrix_ [ndarray of shape (n_samples, n_samples)] Affinity_matrix constructed from samples or precomputed.

n_neighbors_ [int] Number of nearest neighbors effectively used.

**fit** *(X, y=None)*

Fit the model from data in X.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples is the number of samples and n_features is the number of features.
  - If affinity is “precomputed” X : [array-like, sparse matrix], shape (n_samples, n_samples), interpret X as precomputed adjacency graph computed from samples.
- **y** [Ignored]

Returns

- **self** [object] Returns the instance itself.

**fit_transform** *(X, y=None)*

Fit the model from data in X and transform X.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples is the number of samples and n_features is the number of features.
  - If affinity is “precomputed” X : [array-like, sparse matrix] of shape (n_samples, n_samples), interpret X as precomputed adjacency graph computed from samples.
- **y** [Ignored]

Returns

- **X_new** [array-like of shape (n_samples, n_components)]

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [dict] Parameter names mapped to their values.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.23.5 sklearn.manifold.TSNE

class sklearn.manifold.TSNE(**kwargs)

t-distributed Stochastic Neighbor Embedding.

t-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. t-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten’s FAQ [2].

Read more in the User Guide.

Parameters

n_components [int, default=2] Dimension of the embedded space.

perplexity [float, default=30.0] The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Different values can result in significantly different results.

damping [float, default=12.0] Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.
**learning_rate** [float, default=200.0] The learning rate for t-SNE is usually in the range [10.0, 1000.0]. If the learning rate is too high, the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum increasing the learning rate may help.

**n_iter** [int, default=1000] Maximum number of iterations for the optimization. Should be at least 250.

**n_iter_without_progress** [int, default=300] Maximum number of iterations without progress before we abort the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50.

New in version 0.17: parameter *n_iter_without_progress* to control stopping criteria.

**min_grad_norm** [float, default=1e-7] If the gradient norm is below this threshold, the optimization will be stopped.
