\item \textbf{method} \footnotesize{[‘standard’, ‘hessian’, ‘modified’, ‘ltsa’], default=’standard’}
\item \textbf{standard} \footnotesize{[use the standard locally linear embedding algorithm.]} see reference [1]
\item \textbf{hessian} \footnotesize{[use the Hessian eigenmap method. This method requires] \(n_{\text{neighbors}} > n_{\text{components}} * (1 + (n_{\text{components}} + 1) / 2.\) see reference [2]
\item \textbf{modified} \footnotesize{[use the modified locally linear embedding algorithm.]} see reference [3]
\item \textbf{ltsa} \footnotesize{[use local tangent space alignment algorithm]} see reference [4]
\item \textbf{hessian_tol} \footnotesize{[float, default=1e-4]} Tolerance for Hessian eigenmapping method. Only used if method == ‘hessian’
\item \textbf{modified_tol} \footnotesize{[float, default=1e-12]} Tolerance for modified LLE method. Only used if method == ‘modified’
\item \textbf{random_state} \footnotesize{[int, RandomState instance, default=None]} Determines the random number generator when \texttt{solver==’arpack’}. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.
\end{itemize}
**n_jobs** [int or None, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Returns**

Y [array-like, shape [n_samples, n_components]] Embedding vectors.

squared_error [float] Reconstruction error for the embedding vectors. Equivalent to norm(Y - W Y, 'fro') **2**, where W are the reconstruction weights.

**References**

[1], [2], [3], [4]

**Examples using sklearn.manifold.locally_linear_embedding**

- Swiss Roll reduction with LLE

### 7.23.7 sklearn.manifold.smacof

sklearn.manifold.smacof (dissimilarities, *, metric=True, n_components=2, init=None, n_init=8, n_jobs=None, max_iter=300, verbose=0, eps=0.001, random_state=None, return_n_iter=False)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COmplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the stress) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

**Parameters**

dissimilarities [ndarray of shape (n_samples, n_samples)] Pairwise dissimilarities between the points. Must be symmetric.

metric [bool, default=True] Compute metric or nonmetric SMACOF algorithm.

n_components [int, default=2] Number of dimensions in which to immerse the dissimilarities. If an init array is provided, this option is overridden and the shape of init is used to determine the dimensionality of the embedding space.

init [ndarray of shape (n_samples, n_components), default=None] Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.
**n_init** [int, default=8] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If **init** is provided, this option is overridden and a single run is performed.

**n_jobs** [int, default=None] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**max_iter** [int, default=300] Maximum number of iterations of the SMACOF algorithm for a single run.

**verbose** [int, default=0] Level of verbosity.

**eps** [float, default=1e-3] Relative tolerance with respect to stress at which to declare convergence.

**random_state** [int, RandomState instance or None, default=None] Determines the random number generator used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

**return_n_iter** [bool, default=False] Whether or not to return the number of iterations.

Returns

- **X** [ndarray of shape (n_samples, n_components)] Coordinates of the points in a n_components-space.
- **stress** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).
- **n_iter** [int] The number of iterations corresponding to the best stress. Returned only if return_n_iter is set to True.

**Notes**

“Nonmetric multidimensional scaling: a numerical method” Kruskal, J. Psychometrika, 29 (1964)

“Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis” Kruskal, J. Psychometrika, 29, (1964)

### 7.23.8 sklearn.manifold.spectral_embedding

**sklearn.manifold.spectral_embedding(adjacency, *, n_components=8, eigen_solver=None,**

random_state=None, eigen_tol=0.0,

norm_laplacian=True, drop_first=True)

Project the sample on the first eigenvectors of the graph Laplacian.

The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also ‘work’ even if the adjacency variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).
However care must be taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.

Note: Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the User Guide.

Parameters

adjacency [{array-like, sparse graph} of shape (n_samples, n_samples)] The adjacency matrix of the graph to embed.

n_components [int, default=8] The dimension of the projection subspace.

eigen_solver [{'arpack', 'lobpcg', 'amg'}, default=None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities. If None, then 'arpack' is used.

random_state [int, RandomState instance or None, default=None] Determines the random number generator used for the initialization of the lobpcg eigenvectors decomposition when solver == 'amg'. Pass an int for reproducible results across multiple function calls. See Glossary <random_state>.

eigen_tol [float, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

norm_laplacian [bool, default=True] If True, then compute normalized Laplacian.

drop_first [bool, default=True] Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

Returns

embedding [ndarray of shape (n_samples, n_components)] The reduced samples.

Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there graph has many components, the first few eigenvectors will simply uncover the connected components of the graph.

7.23.9 sklearn.manifold.trustworthiness

sklearn.manifold.trustworthiness(X, X_embedded, *, n_neighbors=5, metric='euclidean')
Expresses to what extent the local structure is retained.
The trustworthiness is within [0, 1]. It is defined as

\[ T(k) = 1 - \frac{2}{nk(2n - 3k - 1)} \sum_{i=1}^{n} \sum_{j \in N_k^i} \max(0, (r(i,j) - k)) \]

where for each sample i, \( N_k^i \) are its k nearest neighbors in the output space, and every sample j is its \( r(i,j) \)-th nearest neighbor in the input space. In other words, any unexpected nearest neighbors in the output space are penalised in proportion to their rank in the input space.

- “Neighborhood Preservation in Nonlinear Projection Methods: An Experimental Study” J. Venna, S. Kaski
- “Learning a Parametric Embedding by Preserving Local Structure” L.J.P. van der Maaten

Parameters

X [ndarray of shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘precomputed’ X must be a square distance matrix. Otherwise it contains a sample per row.

X_embedded [ndarray of shape (n_samples, n_components)] Embedding of the training data in low-dimensional space.

n_neighbors [int, default=5] Number of neighbors k that will be considered.

metric [str or callable, default='euclidean'] Which metric to use for computing pairwise distances between samples from the original input space. If metric is ‘precomputed’, X must be a matrix of pairwise distances or squared distances. Otherwise, see the documentation of argument metric in sklearn.pairwise.pairwise_distances for a list of available metrics.

New in version 0.20.

Returns

trustworthiness [float] Trustworthiness of the low-dimensional embedding.

7.24 sklearn.metrics: Metrics

See the Metrics and scoring: quantifying the quality of predictions section and the Pairwise metrics, Affinities and Kernels section of the user guide for further details.

The sklearn.metrics module includes score functions, performance metrics and pairwise metrics and distance computations.

7.24.1 Model Selection Interface

See the The scoring parameter: defining model evaluation rules section of the user guide for further details.

metrics.check_scoring(estimator[, scoring, ...])
Determine scorer from user options.

metrics.get_scorer(scoring)
Get a scorer from string.

metrics.make_scorer(score_func, *[,...])
Make a scorer from a performance metric or loss function.
sklearn.metrics.check_scoring

sklearn.metrics.check_scoring(estimator, scoring=None, *, allow_none=False)
Determine scorer from user options.

A TypeError will be thrown if the estimator cannot be scored.

Parameters

estimator [estimator object implementing ‘fit’] The object to use to fit the data.
scoring [str or callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).
allow_none [bool, default=False] If no scoring is specified and the estimator has no score function, we can either return None or raise an exception.

Returns

scoring [callable] A scorer callable object / function with signature scorer(estimator, X, y).

sklearn.metrics.get_scorer

sklearn.metrics.get_scorer(scoring)
Get a scorer from string.

Read more in the User Guide.

Parameters

scoring [str or callable] Scoring method as string. If callable it is returned as is.

Returns

scorer [callable] The scorer.

sklearn.metrics.make_scorer

sklearn.metrics.make_scorer(score_func, *, greater_is_better=True, needs_proba=False, needs_threshold=False, **kwargs)
Make a scorer from a performance metric or loss function.

This factory function wraps scoring functions for use in GridSearchCV and cross_val_score. It takes a score function, such as accuracy_score, mean_squared_error, adjusted_rand_index or average_precision and returns a callable that scores an estimator’s output. The signature of the call is (estimator, X, y) where estimator is the model to be evaluated, X is the data and y is the ground truth labeling (or None in the case of unsupervised models).

Read more in the User Guide.

Parameters

score_func [callable] Score function (or loss function) with signature score_func(y, y_pred, **kwargs).

greater_is_better [bool, default=True] Whether score_func is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the score_func.
needs_proba [bool, default=False] Whether score_func requires predict_proba to get probability estimates out of a classifier.

If True, for binary y_true, the score function is supposed to accept a 1D y_pred (i.e., probability of the positive class, shape (n_samples,)).

needs_threshold [bool, default=False] Whether score_func takes a continuous decision certainty. This only works for binary classification using estimators that have either a decision_function or predict_proba method.

If True, for binary y_true, the score function is supposed to accept a 1D y_pred (i.e., probability of the positive class or the decision function, shape (n_samples,)).

For example average_precision or the area under the roc curve can not be computed using discrete predictions alone.

**kwargs [additional arguments] Additional parameters to be passed to score_func.

Returns

scorer [callable] Callable object that returns a scalar score; greater is better.

Notes

If needs_proba=False and needs_threshold=False, the score function is supposed to accept the output of predict. If needs_proba=True, the score function is supposed to accept the output of predict_proba (for binary y_true, the score function is supposed to accept probability of the positive class).

If needs_threshold=True, the score function is supposed to accept the output of decision_function.

Examples

```python
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},
... scoring=ftwo_scorer)
```

Examples using sklearn.metrics.make_scorer

- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

7.24.2 Classification metrics

See the Classification metrics section of the user guide for further details.

```python
metrics.accuracy_score(y_true, y_pred, *[, ...])
metrics.auc(x, y) Compute Area Under the Curve (AUC) using the trapezoidal rule.
```
Table 211 – continued from previous page

- `metrics.average_precision_score(y_true, ...)` Compute average precision (AP) from prediction scores.
- `metrics.balanced_accuracy_score(y_true, ...)` Compute the balanced accuracy.
- `metrics.brier_score_loss(y_true, y_prob, *)` Compute the Brier score loss.
- `metrics.classification_report(y_true, y_pred, *)` Build a text report showing the main classification metrics.
- `metrics.cohen_kappa_score(y1, y2, *[...])` Cohen’s kappa: a statistic that measures inter-annotator agreement.
- `metrics.confusion_matrix(y_true, y_pred, *)` Compute confusion matrix to evaluate the accuracy of a classification.
- `metrics.dcg_score(y_true, y_score, *[k, ...])` Compute Discounted Cumulative Gain.
- `metrics.det_curve(y_true, y_score[, ...])` Compute error rates for different probability thresholds.
- `metrics.f1_score(y_true, y_pred, *[...])` Compute the F1 score, also known as balanced F-score or F-measure.
- `metrics.fbeta_score(y_true, y_pred, *, beta)` Compute the F-beta score.
- `metrics.hamming_loss(y_true, y_pred, *[...])` Compute the average Hamming loss.
- `metrics.hinge_loss(y_true, pred_decision, *)` Average hinge loss (non-regularized).
- `metrics.jaccard_score(y_true, y_pred, *[...])` Jaccard similarity coefficient score.
- `metrics.log_loss(y_true, y_pred, *[eps, ...])` Log loss, aka logistic loss or cross-entropy loss.
- `metrics.matthews_corrcoef(y_true, y_pred, *)` Compute the Matthews correlation coefficient (MCC).
- `metrics.multilabel_confusion_matrix(y_true, *)` Compute a confusion matrix for each class or sample.
- `metrics.ndcg_score(y_true, y_score, *[k, ...])` Compute Normalized Discounted Cumulative Gain.
- `metrics.precision_recall_curve(y_true, y_score, *[...])` Compute precision-recall pairs for different probability thresholds.
- `metrics.precision_recall_fscore_support(...)` Compute precision, recall, F-measure and support for each class.
- `metrics.precision_score(y_true, y_pred, *[...])` Compute the precision.
- `metrics.recall_score(y_true, y_pred, *[...])` Compute the recall.
- `metrics.roc_auc_score(y_true, y_score, *[...])` Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.
- `metrics.roc_curve(y_true, y_score, *[...])` Compute Receiver operating characteristic (ROC).
- `metrics.top_k_accuracy_score(y_true, y_score, *)` Top-k Accuracy classification score.
- `metrics.zero_one_loss(y_true, y_pred, *[...])` Zero-one classification loss.

**sklearn.metrics.accuracy_score**

`sklearn.metrics.accuracy_score(y_true, y_pred, *, normalize=True, sample_weight=None)`

Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must exactly match the corresponding set of labels in y_true.

Read more in the User Guide.

Parameters
y_true  [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

y_pred  [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

normalize  [bool, default=True] If False, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] If normalize == True, return the fraction of correctly classified samples (float), else returns the number of correctly classified samples (int).

The best performance is 1 with normalize == True and the number of samples with normalize == False.

See also:

jaccard_score, hamming_loss, zero_one_loss

Notes

In binary and multiclass classification, this function is equal to the jaccard_score function.

Examples

```python
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

Examples using sklearn.metrics.accuracy_score

- Plot classification probability
- Multi-class AdaBoosted Decision Trees
- Probabilistic predictions with Gaussian process classification (GPC)
- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV
- Importance of Feature Scaling
- Classification of text documents using sparse features
sklearn.metrics.auc

sklearn.metrics.auc(x, y)

Compute Area Under the Curve (AUC) using the trapezoidal rule.

This is a general function, given points on a curve. For computing the area under the ROC-curve, see `roc_auc_score`. For an alternative way to summarize a precision-recall curve, see `average_precision_score`.

**Parameters**

- `x` [ndarray of shape (n,)] x coordinates. These must be either monotonic increasing or monotonic decreasing.
- `y` [ndarray of shape, (n,)] y coordinates.

**Returns**

- `auc` [float]

**See also:**

- `roc_auc_score` Compute the area under the ROC curve.
- `average_precision_score` Compute average precision from prediction scores.
- `precision_recall_curve` Compute precision-recall pairs for different probability thresholds.

**Examples**

```python
given_text=
import numpy as np
from sklearn import metrics
y = np.array([1, 1, 2, 2])
pred = np.array([0.1, 0.4, 0.35, 0.8])
fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
métrics.auc(fpr, tpr)
0.75
```

**Examples using sklearn.metrics.auc**

- *Species distribution modeling*
- *Poisson regression and non-normal loss*
- *Tweedie regression on insurance claims*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*
The `sklearn.metrics.average_precision_score` function computes average precision (AP) from prediction scores. AP summarizes a precision-recall curve as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

\[ \text{AP} = \sum_n (R_n - R_{n-1}) P_n \]

where \( P_n \) and \( R_n \) are the precision and recall at the \( n \)th threshold [1]. This implementation is not interpolated and is different from computing the area under the precision-recall curve with the trapezoidal rule, which uses linear interpolation and can be too optimistic.

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the User Guide.

**Parameters**

- `y_true` [ndarray of shape (n_samples,) or (n_samples, n_classes)] True binary labels or binary label indicators.
- `y_score` [ndarray of shape (n_samples,) or (n_samples, n_classes)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measures of decisions (as returned by `decision_function` on some classifiers).
- `average` [{‘micro’, ‘samples’, ‘weighted’, ‘macro’} or None, default=’macro’] If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - ‘micro’: Calculate metrics globally by considering each element of the label indicator matrix as a label.
  - ‘macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - ‘weighted’: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).
  - ‘samples’: Calculate metrics for each instance, and find their average.
  
  Will be ignored when `y_true` is binary.
- `pos_label` [int or str, default=1] The label of the positive class. Only applied to binary `y_true`. For multilabel-indicator `y_true`, `pos_label` is fixed to 1.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `average_precision` [float]

**See also:**

- `roc_auc_score` Compute the area under the ROC curve.
- `precision_recall_curve` Compute precision-recall pairs for different probability thresholds.
Notes

Changed in version 0.19: Instead of linearly interpolating between operating points, precisions are weighted by
the change in recall since the last operating point.

References

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```

Examples using `sklearn.metrics.average_precision_score`

- Precision-Recall

`sklearn.metrics.balanced_accuracy_score`

`sklearn.metrics.balanced_accuracy_score (y_true, y_pred, *, sample_weight=None, adjusted=False)`

Compute the balanced accuracy.

The balanced accuracy in binary and multiclass classification problems to deal with imbalanced datasets. It is
defined as the average of recall obtained on each class.

The best value is 1 and the worst value is 0 when `adjusted=False`.

Read more in the `User Guide`.

New in version 0.20.

Parameters

- `y_true` [1d array-like] Ground truth (correct) target values.
- `y_pred` [1d array-like] Estimated targets as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `adjusted` [bool, default=False] When true, the result is adjusted for chance, so that random
  performance would score 0, and perfect performance scores 1.

Returns

- `balanced_accuracy` [float]

See also:

`recall_score, roc_auc_score`
Notes

Some literature promotes alternative definitions of balanced accuracy. Our definition is equivalent to `accuracy_score` with class-balanced sample weights, and shares desirable properties with the binary case. See the User Guide.

References

[1], [2]

Examples

```python
>>> from sklearn.metrics import balanced_accuracy_score
>>> y_true = [0, 1, 0, 0, 1, 0]
>>> y_pred = [0, 1, 0, 0, 0, 1]
>>> balanced_accuracy_score(y_true, y_pred)
0.625
```

**sklearn.metrics.brier_score_loss**

`sklearn.metrics.brier_score_loss(y_true, y_prob, *, sample_weight=None, pos_label=None)`

Compute the Brier score loss.

The smaller the Brier score loss, the better, hence the naming with “loss”. The Brier score measures the mean squared difference between the predicted probability and the actual outcome. The Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1). It can be decomposed into the sum of refinement loss and calibration loss.

The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another). Which label is considered to be the positive label is controlled via the parameter `pos_label`, which defaults to the greater label unless `y_true` is all 0 or all -1, in which case `pos_label` defaults to 1.

Read more in the User Guide.

**Parameters**

- **y_true** [array of shape (n_samples,)] True targets.
- **y_prob** [array of shape (n_samples,)] Probabilities of the positive class.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **pos_label** [int or str, default=None] Label of the positive class. `pos_label` will be inferred in the following manner:
  - if `y_true` in {-1, 1} or {0, 1}, `pos_label` defaults to 1;
  - else if `y_true` contains string, an error will be raised and `pos_label` should be explicitly specified;
  - otherwise, `pos_label` defaults to the greater label, i.e. `np.unique(y_true)[-1].`

**Returns**

- **score** [float] Brier score loss.
References

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_true_categorical = np.array(["spam", "ham", "ham", "spam"])
>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true_categorical, y_prob, pos_label="ham")
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.0
```

Examples using `sklearn.metrics.brier_score_loss`

- Probability Calibration curves
- Probability calibration of classifiers

`sklearn.metrics.classification_report`

`sklearn.metrics.classification_report` (`y_true`, `y_pred`, *, `labels=None`, `target_names=None`, `sample_weight=None`, `digits=2`, `output_dict=False`, `zero_division='warn'`)

Build a text report showing the main classification metrics.

Read more in the User Guide.

Parameters

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like of shape (n_labels,), default=None] Optional list of label indices to include in the report.
- `target_names` [list of str of shape (n_labels,), default=None] Optional display names matching the labels (same order).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `digits` [int, default=2] Number of digits for formatting output floating point values. When `output_dict` is True, this will be ignored and the returned values will not be rounded.
- `output_dict` [bool, default=False] If True, return output as dict.

New in version 0.20.
zero_division [“warn”, 0 or 1, default=“warn”] Sets the value to return when there is a zero division. If set to “warn”, this acts as 0, but warnings are also raised.

Returns

report [string / dict] Text summary of the precision, recall, F1 score for each class. Dictionary returned if output_dict is True. Dictionary has the following structure:

```python
{'label 1': {'precision': 0.5, 'recall': 1.0, 'f1-score': 0.67, 'support': 1},
'label 2': {...}, ...
}
```

The reported averages include macro average (averaging the unweighted mean per label), weighted average (averaging the support-weighted mean per label), and sample average (only for multilabel classification). Micro average (averaging the total true positives, false negatives and false positives) is only shown for multi-label or multi-class with a subset of classes, because it corresponds to accuracy otherwise and would be the same for all metrics. See also precision_recall_fscore_support for more details on averages.

Note that in binary classification, recall of the positive class is also known as “sensitivity”; recall of the negative class is “specificity”.

See also:

precision_recall_fscore_support, confusion_matrix
multilabel_confusion_matrix

Examples

```python
>>> from sklearn.metrics import classification_report

>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']

>>> print(classification_report(y_true, y_pred, target_names=target_names))

precision    recall    f1-score   support
     class 0:       0.50      1.00      0.67        1
     class 1:       0.00      0.00      0.00        1
     class 2:       1.00      0.67      0.80        3

`sklearn.metrics.cohen_kappa_score`

`sklearn.metrics.cohen_kappa_score(y1, y2, *, labels=None, weights=None, sample_weight=None)`

Cohen’s kappa: a statistic that measures inter-annotator agreement.

This function computes Cohen’s kappa [1], a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

$$\kappa = (p_o - p_e) / (1 - p_e)$$

where $p_o$ is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and $p_e$ is the expected agreement when both annotators assign labels randomly. $p_e$ is estimated using a per-annotator empirical prior over the class labels [2].

Read more in the *User Guide*.

**Parameters**

- `y1` [array of shape (n_samples,)] Labels assigned by the first annotator.
- `y2` [array of shape (n_samples,)] Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping `y1` and `y2` doesn’t change the value.
- `labels` [array-like of shape (n_classes,), default=None] List of labels to index the matrix. This may be used to select a subset of labels. If None, all labels that appear at least once in `y1` or `y2` are used.
- `weights` [{‘linear’, ‘quadratic’}, default=None] Weighting type to calculate the score. None means no weighted; “linear” means linear weighted; “quadratic” means quadratic weighted.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**
The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

sklearn.metrics.confusion_matrix

sklearn.metrics.confusion_matrix(y_true, y_pred, *, labels=None, sample_weight=None, normalize=None)

Compute confusion matrix to evaluate the accuracy of a classification.

By definition a confusion matrix $C$ is such that $C_{i,j}$ is equal to the number of observations known to be in group $i$ and predicted to be in group $j$.

Thus in binary classification, the count of true negatives is $C_{0,0}$, false negatives is $C_{1,0}$, true positives is $C_{1,1}$ and false positives is $C_{0,1}$.

Read more in the User Guide.

Parameters

y_true [array-like of shape (n_samples,)] Ground truth (correct) target values.

y_pred [array-like of shape (n_samples,)] Estimated targets as returned by a classifier.

labels [array-like of shape (n_classes), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If None is given, those that appear at least once in y_true or y_pred are used in sorted order.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

New in version 0.18.

normalize [{‘true’, ‘pred’, ‘all’}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.

Returns

C [ndarray of shape (n_classes, n_classes)] Confusion matrix whose i-th row and j-th column entry indicates the number of samples with true label being i-th class and predicted label being j-th class.

See also:

plot_confusion_matrix Plot Confusion Matrix.

ConfusionMatrixDisplay Confusion Matrix visualization.
References

[1]

Examples

```python
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])

>>> y_true = ["cat", "ant", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "ant", "cat"]
>>> confusion_matrix(y_true, y_pred, labels=["ant", "bird", "cat"])
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

In the binary case, we can extract true positives, etc as follows:

```python
>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)
```

- Visualizations with Display Objects
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
- Classification of text documents using sparse features

`sklearn.metrics.dcg_score`

`sklearn.metrics.dcg_score` computes Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. This ranking metric yields a high value if true labels are ranked high by `y_score`.

Usually the Normalized Discounted Cumulative Gain (NDCG, computed by `ndcg_score`) is preferred.

Parameters

- `y_true` [ndarray of shape (n_samples, n_labels)] True targets of multilabel classification, or true scores of entities to be ranked.
**y_score** [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).

**k** [int, default=None] Only consider the highest k scores in the ranking. If None, use all outputs.

**log_base** [float, default=2] Base of the logarithm used for the discount. A low value means a sharper discount (top results are more important).

**sample_weight** [ndarray of shape (n_samples,), default=None] Sample weights. If None, all samples are given the same weight.

**ignore_ties** [bool, default=False] Assume that there are no ties in y_score (which is likely to be the case if y_score is continuous) for efficiency gains.

**Returns**

**discounted_cumulative_gain** [float] The averaged sample DCG scores.

**See also:**

**ndcg_score** The Discounted Cumulative Gain divided by the Ideal Discounted Cumulative Gain (the DCG obtained for a perfect ranking), in order to have a score between 0 and 1.

**References**

Wikipedia entry for Discounted Cumulative Gain.

**Examples**

```python
>>> from sklearn.metrics import dcg_score
>>> # we have ground-truth relevance of some answers to a query:
>>> true_relevance = np.array([[10, 0, 0, 1, 5]])
>>> # we predict scores for the answers
>>> scores = np.array([[.1, .2, .3, 4, 70]])
>>> dcg_score(true_relevance, scores)
9.49...
>>> # we can set k to truncate the sum; only top k answers contribute
>>> dcg_score(true_relevance, scores, k=2)
5.63...
>>> # now we have some ties in our prediction
>>> scores = np.array([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average true
>>> # relevance of our top predictions: (10 + 5) / 2 = 7.5
>>> dcg_score(true_relevance, scores, k=1)
7.5
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
```
>>> # wrong results:
>>> dcg_score(true_relevance,
...    scores, k=1, ignore_ties=True)
5.0

**sklearn.metrics.det_curve**

`sklearn.metrics.det_curve(y_true, y_score, pos_label=None, sample_weight=None)`

Compute error rates for different probability thresholds.

**Note:** This metric is used for evaluation of ranking and error tradeoffs of a binary classification task.

Read more in the *User Guide*.

New in version 0.24.

**Parameters**

- `y_true` [ndarray of shape (n_samples,)] True binary labels. If labels are not either {-1, 1} or {0, 1}, then pos_label should be explicitly given.
- `y_score` [ndarray of shape of (n_samples,)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `pos_label` [int or str, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `fpr` [ndarray of shape (n_thresholds,)] False positive rate (FPR) such that element i is the false positive rate of predictions with score >= thresholds[i]. This is occasionally referred to as false acceptance probability or fall-out.
- `fnr` [ndarray of shape (n_thresholds,)] False negative rate (FNR) such that element i is the false negative rate of predictions with score >= thresholds[i]. This is occasionally referred to as false rejection or miss rate.
- `thresholds` [ndarray of shape (n_thresholds,)] Decreasing score values.

**See also:**

- `plot_det_curve` Plot detection error tradeoff (DET) curve.
- `DetCurveDisplay` DET curve visualization.
- `roc_curve` Compute Receiver operating characteristic (ROC) curve.
- `precision_recall_curve` Compute precision-recall curve.
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import det_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, fnr, thresholds = det_curve(y_true, y_scores)
>>> fpr
array([0.5, 0.5, 0.])
>>> fnr
array([0., 0.5, 0.5])
>>> thresholds
array([0.35, 0.4 , 0.8 ])
```

Examples using `sklearn.metrics.det_curve`

- Detection error tradeoff (DET) curve

`sklearn.metrics.f1_score`

`sklearn.metrics.f1_score(y_true, y_pred, *, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Compute the F1 score, also known as balanced F-score or F-measure.

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

\[
F1 = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}}
\]

In the multi-class and multi-label case, this is the average of the F1 score of each class with weighting depending on the `average` parameter.

Read more in the `User Guide`.

Parameters

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like, default=None] The set of labels to include when `average != 'binary', and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
  Changed in version 0.17: Parameter `labels` improved for multiclass problem.
- `pos_label` [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
average [{‘micro’, ‘macro’, ‘samples’, ‘weighted’, ‘binary’} or None, default=’binary’] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

’binary’: Only report results for the class specified by pos_label. This is applicable only if targets (y_{true,pred}) are binary.

’micro’: Calculate metrics globally by counting the total true positives, false negatives and false positives.

’macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

’weighted’: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

’samples’: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

zero_division [“warn”, 0 or 1, default=”warn”] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to “warn”, this acts as 0, but warnings are also raised.

Returns

f1_score [float or array of float, shape = [n_unique_labels]] F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

See also:

fbeta_score, precision_recall_fscore_support, jaccard_score
multilabel_confusion_matrix

Notes

When true positive + false positive == 0, precision is undefined. When true positive + false negative == 0, recall is undefined. In such cases, by default the metric will be set to 0, as will f-score, and UndefinedMetricWarning will be raised. This behavior can be modified with zero_division.

Examples

```python
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([0.8, 0. , 0. ])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> f1_score(y_true, y_pred, zero_division=1)
1.0...
```

Examples using `sklearn.metrics.f1_score`

- Probability Calibration curves
- Precision-Recall

`sklearn.metrics.fbeta_score`

`sklearn.metrics.fbeta_score(y_true, y_pred, *, beta, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Compute the F-beta score.

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The `beta` parameter determines the weight of recall in the combined score. `beta < 1` lends more weight to precision, while `beta > 1` favors recall (`beta -> 0` considers only precision, `beta -> +inf` only recall).

Read more in the *User Guide*.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `beta` [float] Determines the weight of recall in the combined score.
- `labels` [array-like, default=None] The set of labels to include when `average` is 'binary', and their order if `average` is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

 Changed in version 0.17: Parameter `labels` improved for multiclass problem.
pos_label [str or int, default=1] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.

average [{'micro', 'macro', 'samples', 'weighted', 'binary'} or None default='binary'] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'binary': Only report results for the class specified by pos_label. This is applicable only if targets \(y_{true,pred}\) are binary.

'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.

'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'weighted': Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

zero_division ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to “warn”, this acts as 0, but warnings are also raised.

Returns

fbeta_score [float (if average is not None) or array of float, shape = [n_unique_labels]] F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

See also:

precision_recall_fscore_support, multilabel_confusion_matrix

Notes

When true positive + false positive == 0 or true positive + false negative == 0, f-score returns 0 and raises UndefinedMetricWarning. This behavior can be modified with zero_division.

array([0.71..., 0., 0.])
```

**sklearn.metrics.hamming_loss**

`sklearn.metrics.hamming_loss(y_true, y_pred, *, sample_weight=None)`

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the User Guide.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

New in version 0.18.

**Returns**

- `loss` [float or int] Return the average Hamming loss between element of `y_true` and `y_pred`.

**See also:**

`accuracy_score`, `jaccard_score`, `zero_one_loss`

**Notes**

In multiclass classification, the Hamming loss corresponds to the Hamming distance between `y_true` and `y_pred` which is equivalent to the subset `zero_one_loss` function, when `normalize` parameter is set to True.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does not entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes only the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss, when `normalize` parameter is set to True. It is always between 0 and 1, lower being better.
References

[1], [2]

Examples

```python
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

Examples using sklearn.metrics.hamming_loss

- Model Complexity Influence

sklearn.metrics.hinge_loss

sklearn.metrics.hinge_loss(y_true, pred_decision, *, labels=None, sample_weight=None)

Average hinge loss (non-regularized).

In binary class case, assuming labels in y_true are encoded with +1 and -1, when a prediction mistake is made, margin = y_true * pred_decision is always negative (since the signs disagree), implying 1 - margin is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.

In multiclass case, the function expects that either all the labels are included in y_true or an optional labels argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer’s method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the User Guide.

Parameters

- **y_true** [array of shape (n_samples,)] True target, consisting of integers of two values. The positive label must be greater than the negative label.
- **pred_decision** [array of shape (n_samples,) or (n_samples, n_classes)] Predicted decisions, as output by decision_function (floats).
- **labels** [array-like, default=None] Contains all the labels for the problem. Used in multiclass hinge loss.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **loss** [float]
References

[1], [2], [3]

Examples

```python
>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss

>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(random_state=0)
>>> pred_decision = est.decision_function([-2], [3], [0.5])
>>> pred_decision
array([-2.18..., 2.36..., 0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...
```

In the multiclass case:

```python
>>> import numpy as np

>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC()
>>> pred_decision = est.decision_function([-1], [2], [3])
>>> y_true = [0, 2, 3]
>>> hinge_loss(y_true, pred_decision, labels=labels)
0.56...
```

**sklearn.metrics.jaccard_score**

sklearn.metrics.jaccard_score(y_true, y_pred, *, labels=None, pos_label=1, average='binary',
sample_weight=None, zero_division='warn')

Jaccard similarity coefficient score.

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in y_true.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **labels** [array-like of shape (n_classes,), default=None] The set of labels to include when average ! = 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro
average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

**pos_label** [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [(None, ‘micro’, ‘macro’, ‘samples’, ‘weighted’, ‘binary’), default=’binary’] If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

- **'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.
- **'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.
- **'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
- **'weighted'**: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance.
- **'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**zero_division** ["warn", {0.0, 1.0}, default="warn"] Sets the value to return when there is a zero division, i.e. when there are no negative values in predictions and labels. If set to "warn", this acts like 0, but a warning is also raised.

**Returns**

- **score** [float (if average is not None) or array of floats, shape = [n_unique_labels]]

See also:

- `accuracy_score`, `f_score`, `multilabel_confusion_matrix`

**Notes**

`jaccard_score` may be a poor metric if there are no positives for some samples or classes. Jaccard is undefined if there are no true or predicted labels, and our implementation will return a score of 0 with a warning.

**References**

[1]
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import jaccard_score
>>> y_true = np.array([[0, 1, 1],
... ... [1, 1, 0]])
>>> y_pred = np.array([[1, 1, 1],
... ... [1, 0, 0]])
In the binary case:
```n
```python
>>> jaccard_score(y_true[0], y_pred[0])
0.6666...
```

In the multilabel case:
```python
>>> jaccard_score(y_true, y_pred, average='samples')
0.5833...
>>> jaccard_score(y_true, y_pred, average='macro')
0.6666...
>>> jaccard_score(y_true, y_pred, average=None)
array([0.5, 0.5, 1.])
```

In the multiclass case:
```python
>>> y_pred = [0, 2, 1, 2]
>>> y_true = [0, 1, 2, 2]
>>> jaccard_score(y_true, y_pred, average=None)
array([1. , 0. , 0.33...])
```

Examples using sklearn.metrics.jaccard_score

- Classifier Chain

sklearn.metrics.log_loss

sklearn.metrics.log_loss(y_true, y_pred, *, eps=1e-15, normalize=True, sample_weight=None, labels=None)

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of a logistic model that returns y_pred probabilities for its training data y_true. The log loss is only defined for two or more labels. For a single sample with true label \( y \in \{0, 1\} \) and and a probability estimate \( p = Pr(y = 1) \), the log loss is:

\[
L_{\log}(y, p) = - (y \log(p) + (1 - y) \log(1 - p))
\]

Read more in the User Guide.

Parameters

- **y_true** [array-like or label indicator matrix] Ground truth (correct) labels for n_samples samples.
- **y_pred** [array-like of float, shape = (n_samples, n_classes) or (n_samples,)] Predicted probabilities, as returned by a classifier’s predict_proba method. If y_pred.shape =
The probabilities provided are assumed to be that of the positive class. The labels in \texttt{y\_pred} are assumed to be ordered alphabetically, as done by \texttt{preprocessing.LabelBinarizer}.

\texttt{eps} [float, default=1e-15] Log loss is undefined for \(p=0\) or \(p=1\), so probabilities are clipped to \(\max(\texttt{eps}, \min(1 - \texttt{eps}, \texttt{p}))\).

\texttt{normalize} [bool, default=True] If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.

\texttt{sample\_weight} [array-like of shape (n\_samples,), default=None] Sample weights.

\texttt{labels} [array-like, default=None] If not provided, labels will be inferred from \texttt{y\_true}. If \texttt{labels} is None and \texttt{y\_pred} has shape (n\_samples,) the labels are assumed to be binary and are inferred from \texttt{y\_true}.

New in version 0.18.

Returns

\texttt{loss} [float]

Notes

The logarithm used is the natural logarithm (base-e).

References

Examples

```python
>>> from sklearn.metrics import log_loss
>>> log_loss(['spam', 'ham', 'ham', 'spam'],
          [[.1, .9], [.9, .1], [.8, .2], [.35, .65]])
0.21616...
```

Examples using \texttt{sklearn.metrics.log\_loss}

- \texttt{Probability\ Caliberation\ for\ 3-class\ classification}
- \texttt{Probabilistic\ predictions\ with\ Gaussian\ process\ classification\ (GPC)}

\texttt{sklearn.metrics.matthews\_corrcoef}

\texttt{sklearn.metrics.matthews\_corrcoef (y\_true, y\_pred, *, sample\_weight=None)}

Compute the Matthews correlation coefficient (MCC).

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary and multiclass classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]
Binary and multiclass labels are supported. Only in the binary case does this relate to information about true and false positives and negatives. See references below.

Read more in the *User Guide*.

**Parameters**

- `y_true` [array, shape = [n_samples]] Ground truth (correct) target values.
- `y_pred` [array, shape = [n_samples]] Estimated targets as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
  
  New in version 0.18.

**Returns**

- `mcc` [float] The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an average random prediction and -1 and inverse prediction).

**References**

[1], [2], [3], [4]

**Examples**

```python
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

**sklearn.metrics.multilabel_confusion_matrix**

`sklearn.metrics.multilabel_confusion_matrix(y_true, y_pred, *, sample_weight=None, labels=None, samplewise=False)`

Compute a confusion matrix for each class or sample.

New in version 0.21.

Compute class-wise (default) or sample-wise (samplewise=True) multilabel confusion matrix to evaluate the accuracy of a classification, and output confusion matrices for each class or sample.

In multilabel confusion matrix $MCM$, the count of true negatives is $MCM_{0,0}$, false negatives is $MCM_{1,0}$, true positives is $MCM_{1,1}$ and false positives is $MCM_{0,1}$.

Multiclass data will be treated as if binarized under a one-vs-rest transformation. Returned confusion matrices will be in the order of sorted unique labels in the union of (y_true, y_pred).

Read more in the *User Guide*.

**Parameters**

- `y_true` [{array-like, sparse matrix} of shape (n_samples, n_outputs) or (n_samples,)] Ground truth (correct) target values.
- `y_pred` [{array-like, sparse matrix} of shape (n_samples, n_outputs) or (n_samples,)] Estimated targets as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
**labels** [array-like of shape (n_classes,), default=None] A list of classes or column indices to select some (or to force inclusion of classes absent from the data).

**samplewise** [bool, default=False] In the multilabel case, this calculates a confusion matrix per sample.

**Returns**

**multi_confusion** [ndarray of shape (n_outputs, 2, 2)] A 2x2 confusion matrix corresponding to each output in the input. When calculating class-wise multi_confusion (default), then n_outputs = n_labels; when calculating sample-wise multi_confusion (samplewise=True), n_outputs = n_samples. If labels is defined, the results will be returned in the order specified in labels, otherwise the results will be returned in sorted order by default.

**See also:**

**confusion_matrix**

**Notes**

The multilabel_confusion_matrix calculates class-wise or sample-wise multilabel confusion matrices, and in multiclass tasks, labels are binarized under a one-vs-rest way; while confusion_matrix calculates one confusion matrix for confusion between every two classes.

**Examples**

**Multilabel-indicator case:**

```python
>>> import numpy as np
>>> from sklearn.metrics import multilabel_confusion_matrix
>>> y_true = np.array([[1, 0, 1],
...                    [0, 1, 0]])
>>> y_pred = np.array([[1, 0, 0],
...                    [0, 1, 1]])
>>> multilabel_confusion_matrix(y_true, y_pred)
array([[1, 0],
       [0, 1]])
```

**Multiclass case:**

```python
>>> y_true = ["cat", "ant", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "ant", "cat"]
>>> multilabel_confusion_matrix(y_true, y_pred, labels=["ant", "bird", "cat"])
array([[3, 1],
       [0, 2]],
       [[5, 0],
       [1, 0]])
```

(continues on next page)
sklearn.metrics.ndcg_score

`sklearn.metrics.ndcg_score(y_true, y_score, *, k=None, sample_weight=None, ignore_ties=False)`

Compute Normalized Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. Then divide by the best possible score (Ideal DCG, obtained for a perfect ranking) to obtain a score between 0 and 1.

This ranking metric yields a high value if true labels are ranked high by `y_score`.

**Parameters**

- `y_true` [ndarray of shape (n_samples, n_labels)] True targets of multilabel classification, or true scores of entities to be ranked.
- `y_score` [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `k` [int, default=None] Only consider the highest k scores in the ranking. If None, use all outputs.
- `sample_weight` [ndarray of shape (n_samples,), default=None] Sample weights. If None, all samples are given the same weight.
- `ignore_ties` [bool, default=False] Assume that there are no ties in y_score (which is likely to be the case if y_score is continuous) for efficiency gains.

**Returns**

- `normalized_discounted_cumulative_gain` [float in [0., 1.]] The averaged NDCG scores for all samples.

**See also:**

- `dcg_score` Discounted Cumulative Gain (not normalized).

**References**

Wikipedia entry for Discounted Cumulative Gain

Examples

```python
>>> from sklearn.metrics import ndcg_score
>>> # we have ground-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict some scores (relevance) for the answers
>>> scores = np.asarray([[-.1, -.2, -.3, .4, 70]])
>>> ndcg_score(true_relevance, scores)
0.69...
>>> scores = np.asarray([[-.05, 1.1, 1., -.5, .0]])
>>> ndcg_score(true_relevance, scores)
0.49...
>>> # we can set k to truncate the sum; only top k answers contribute.
>>> ndcg_score(true_relevance, scores, k=4)
0.35...
>>> # the normalization takes k into account so a perfect answer
>>> # would still get 1.0
>>> ndcg_score(true_relevance, true_relevance, k=4)
1.0
>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average (normalized)
>>> # true relevance of our top predictions: (10 / 10 + 5 / 10) / 2 = .75
>>> ndcg_score(true_relevance, scores, k=1)
0.75
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
>>> # wrong results:
>>> ndcg_score(true_relevance, ...
...    scores, k=1, ignore_ties=True)
0.5
```

`scklearn.metrics.precision_recall_curve`

`scklearn.metrics.precision_recall_curve`(y_true, probas_pred, *, pos_label=None, sample_weight=None)

Compute precision-recall pairs for different probability thresholds.

Note: this implementation is restricted to the binary classification task.

The precision is the ratio \( \frac{tp}{tp + fp} \) where \( tp \) is the number of true positives and \( fp \) the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio \( \frac{tp}{tp + fn} \) where \( tp \) is the number of true positives and \( fn \) the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the y axis.

Read more in the User Guide.

Parameters

- **y_true** [ndarray of shape (n_samples,)] True binary labels. If labels are not either \{-1, 1\} or \{0, 1\}, then pos_label should be explicitly given.
- **probas_pred** [ndarray of shape (n_samples,)] Estimated probabilities or output of a decision function.
pos_label [int or str, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

precision [ndarray of shape (n_thresholds + 1,)] Precision values such that element i is the precision of predictions with score >= thresholds[i] and the last element is 1.

recall [ndarray of shape (n_thresholds + 1,)] Decreasing recall values such that element i is the recall of predictions with score >= thresholds[i] and the last element is 0.

thresholds [ndarray of shape (n_thresholds,)] Increasing thresholds on the decision function used to compute precision and recall. n_thresholds <= len(np.unique(probas_pred)).

See also:

plot_precision_recall_curve Plot Precision Recall Curve for binary classifiers.

PrecisionRecallDisplay Precision Recall visualization.

average_precision_score Compute average precision from prediction scores.

det_curve Compute error rates for different probability thresholds.

roc_curve Compute Receiver operating characteristic (ROC) curve.

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> precision, recall, thresholds = precision_recall_curve(y_true, y_scores)
>>> precision
array([0.66666667, 0.5 , 1. , 1. ])
>>> recall
array([1. , 0.5, 0.5, 0. ])
>>> thresholds
array([0.35, 0.4 , 0.8 ])
```

Examples using sklearn.metrics.precision_recall_curve

- Visualizations with Display Objects
- Precision-Recall
Compute precision, recall, F-measure and support for each class.

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio $\frac{tp}{tp + fn}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of $\beta$. $\beta == 1.0$ means recall and precision are equally important.

The support is the number of occurrences of each class in $y_{true}$.

If $pos\_label$ is None and in binary classification, this function returns the average precision, recall and F-measure if $average$ is one of 'micro', 'macro', 'weighted' or 'samples'.

Read more in the User Guide.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **beta** [float, default=1.0] The strength of recall versus precision in the F-score.
- **labels** [array-like, default=None] The set of labels to include when $average$ != 'binary', and their order if $average$ is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in $y_{true}$ and $y_{pred}$ are used in sorted order.
- **pos_label** [str or int, default=1] The class to report if $average$='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and $average$ != 'binary' will report scores for that label only.
- **average** [{'binary', 'micro', 'macro', 'samples', 'weighted'}, default=None] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - 'binary': Only report results for the class specified by $pos\_label$. This is applicable only if targets ($y_{true,pred}$) are binary.
  - 'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
'weighted': Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

warn_for [tuple or set, for internal use] This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

zero_division ["warn", 0 or 1, default="warn"]

Sets the value to return when there is a zero division:

- recall: when there are no positive labels
- precision: when there are no positive predictions
- f-score: both

If set to “warn”, this acts as 0, but warnings are also raised.

Returns

precision [float (if average is not None) or array of float, shape = [n_unique_labels]]
recall [float (if average is not None) or array of float, shape = [n_unique_labels]]
fbeta_score [float (if average is not None) or array of float, shape = [n_unique_labels]]
support [None (if average is not None) or array of int, shape = [n_unique_labels]] The number of occurrences of each label in y_true.

Notes

When true positive + false positive == 0, precision is undefined. When true positive + false negative == 0, recall is undefined. In such cases, by default the metric will be set to 0, as will f-score, and UndefinedMetricWarning will be raised. This behavior can be modified with zero_division.

References

[1], [2], [3]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
(0.22..., 0.33..., 0.26..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
(0.22..., 0.33..., 0.26..., None)
```
It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging:

```python
>>> precision_recall_fscore_support(y_true, y_pred, average=None, ...
... labels=['pig', 'dog', 'cat'])
(array([0. , 0. , 0.66...]),
 array([0., 0., 1.]), array([0. , 0. , 0.8]),
 array([2, 2, 2]))
```

**sklearn.metrics.precision_score**

```python
sklearn.metrics.precision_score(y_true, y_pred, *, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')
```

Compute the precision.

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

Read more in the User Guide.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like, default=None] The set of labels to include when `average != 'binary'` and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
  
  Changed in version 0.17: Parameter `labels` improved for multiclass problem.
- `pos_label` [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- `average` [{‘micro’, ‘macro’, ‘samples’, ‘weighted’, ‘binary’} default='binary'] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - `'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_true`,`y_pred`) are binary.
  - `'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - `'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `'weighted'`: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**zero_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

**Returns**

**precision** [float (if average is not None) or array of float of shape (n_unique_labels,)] Precision of the positive class in binary classification or weighted average of the precision of each class for the multiclass task.

**See also:**

`precision_recall_fscore_support`, `multilabel_confusion_matrix`

**Notes**

When `true positive + false positive == 0`, precision returns 0 and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

**Examples**

```python
>>> from sklearn.metrics import precision_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> precision_score(y_true, y_pred, average='macro')
0.22...
>>> precision_score(y_true, y_pred, average='micro')
0.33...
>>> precision_score(y_true, y_pred, average='weighted')
0.22...
>>> precision_score(y_true, y_pred, average=None)
array([0.66..., 0. , 0. ])
>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> precision_score(y_true, y_pred, average=None)
array([0.33..., 0. , 0. ])
>>> precision_score(y_true, y_pred, average=None, zero_division=1)
array([0.33..., 1. , 1. ])
```

**Examples using sklearn.metrics.precision_score**

- **Probability Calibration curves**
- **Precision-Recall**
sklearn.metrics.recall_score

```python
sklearn.metrics.recall_score(y_true, y_pred, *, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')
```

Compute the recall.

The recall is the ratio \( \frac{tp}{tp + fn} \) where \( tp \) is the number of true positives and \( fn \) the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the User Guide.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like, default=None] The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
  
  Changed in version 0.17: Parameter `labels` improved for multiclass problem.
- `pos_label` [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- `average` ['micro', 'macro', 'samples', 'weighted', 'binary'] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

  - `'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_(true,pred)`) are binary.
  - `'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - `'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `'weighted'`: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
  - `'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `zero_division` ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

**Returns**

7.24. sklearn.metrics: Metrics 2347
recall  [float (if average is not None) or array of float of shape (n_unique_labels,)] Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

See also:

precision_recall_fscore_support, balanced_accuracy_score
multilabel_confusion_matrix

Notes

When true positive + false negative == 0, recall returns 0 and raises UndefinedMetricWarning. This behavior can be modified with zero_division.

Examples

```python
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([1., 0., 0.])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> recall_score(y_true, y_pred, average=None)
array([0.5, 0., 0.])
>>> recall_score(y_true, y_pred, average=None, zero_division=1)
array([0.5, 1., 1.])
```

Examples using sklearn.metrics.recall_score

- Probability Calibration curves
- Precision-Recall

sklearn.metrics.roc_auc_score

sklearn.metrics.roc_auc_score(y_true, y_score, *, average='macro', sample_weight=None, max_fpr=None, multi_class='raise', labels=None)

Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.

Note: this implementation can be used with binary, multiclass and multilabel classification, but some restrictions apply (see Parameters).

Read more in the User Guide.

Parameters
**y_true** [array-like of shape (n_samples,) or (n_samples, n_classes)] True labels or binary label indicators. The binary and multiclass cases expect labels with shape (n_samples,) while the multilabel case expects binary label indicators with shape (n_samples, n_classes).

**y_score** [array-like of shape (n_samples,) or (n_samples, n_classes)] Target scores.

- In the binary case, it corresponds to an array of shape (n_samples,). Both probability estimates and non-thresholded decision values can be provided. The probability estimates correspond to the **probability of the class with the greater label**, i.e. estimator.classes_[1] and thus estimator.predict_proba(X, y)[:, 1]. The decision values corresponds to the output of estimator.decision_function(X, y). See more information in the User guide;

- In the multiclass case, it corresponds to an array of shape (n_samples, n_classes) of probability estimates provided by the predict_proba method. The probability estimates must sum to 1 across the possible classes. In addition, the order of the class scores must correspond to the order of labels, if provided, or else to the numerical or lexicographical order of the labels in y_true. See more information in the User guide;

- In the multilabel case, it corresponds to an array of shape (n_samples, n_classes). Probability estimates are provided by the predict_proba method and the non-thresholded decision values by the decision_function method. The probability estimates correspond to the **probability of the class with the greater label for each output** of the classifier. See more information in the User guide.

**average** [={'micro', 'macro', 'samples', 'weighted'} or None, default='macro'] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data: Note: multiclass ROC AUC currently only handles the ‘macro’ and ‘weighted’ averages.

- 'micro': Calculate metrics globally by considering each element of the label indicator matrix as a label.

- 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

- 'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

- 'samples': Calculate metrics for each instance, and find their average.

Will be ignored when y_true is binary.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**max_fpr** [float > 0 and <= 1, default=None] If not None, the standardized partial AUC [2] over the range [0, max_fpr] is returned. For the multiclass case, max_fpr, should be either equal to None or 1.0 as AUC ROC partial computation currently is not supported for multiclass.

**multi_class** [['raise', 'ovr', 'ovo'], default='raise'] Only used for multiclass targets. Determines the type of configuration to use. The default value raises an error, so either 'ovr' or 'ovo' must be passed explicitly.

- 'ovr': Stands for One-vs-rest. Computes the AUC of each class against the rest [3] [4]. This treats the multiclass case in the same way as the multilabel case. Sensitive to class imbalance even when average == 'macro', because class imbalance affects the composition of each of the ‘rest’ groupings.

- 'ovo': Stands for One-vs-one. Computes the average AUC of all possible pairwise combinations of classes [5]. Insensitive to class imbalance when average == 'macro'.
labels  [array-like of shape (n_classes,), default=None] Only used for multiclass targets. List of labels that index the classes in y_score. If None, the numerical or lexicographical order of the labels in y_true is used.

Returns

    auc  [float]

See also:

    average_precision_score  Area under the precision-recall curve.
    roc_curve  Compute Receiver operating characteristic (ROC) curve.
    plot_roc_curve  Plot Receiver operating characteristic (ROC) curve.

Examples

Binary case:

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.metrics import roc_auc_score

>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = LogisticRegression(solver="liblinear", random_state=0).fit(X, y)
>>> roc_auc_score(y, clf.predict_proba(X)[:, 1])
0.99...
>>> roc_auc_score(y, clf.decision_function(X))
0.99...
```

Multiclass case:

```python
>>> from sklearn.datasets import load_iris

>>> X, y = load_iris(return_X_y=True)
>>> clf = LogisticRegression(solver="liblinear").fit(X, y)
>>> roc_auc_score(y, clf.predict_proba(X), multi_class='ovr')
0.99...
```

Multilabel case:

```python
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.multioutput import MultiOutputClassifier

>>> X, y = make_multilabel_classification(random_state=0)
>>> clf = MultiOutputClassifier(clf).fit(X, y)

>>> y_pred = clf.predict_proba(X)
>>> # extract the positive columns for each output
>>> y_pred = np.transpose([[pred[:, 1] for pred in y_pred]])
>>> roc_auc_score(y, y_pred, average='None')
array([0.82..., 0.86..., 0.94..., 0.85..., 0.94...])
```

(continues on next page)
Examples using `sklearn.metrics.roc_auc_score`

- **Release Highlights for scikit-learn 0.22**
- **Receiver Operating Characteristic (ROC) with cross validation**
- **Receiver Operating Characteristic (ROC)**

### sklearn.metrics.roc_curve

```python
sklearn.metrics.roc_curve(y_true, y_score, *, pos_label=None, sample_weight=None, drop_intermediate=True)
```

Compute Receiver operating characteristic (ROC).

Note: this implementation is restricted to the binary classification task.

Parameters

- `y_true` [ndarray of shape (n_samples,)] True binary labels. If labels are not either {-1, 1} or {0, 1}, then pos_label should be explicitly given.
- `y_score` [ndarray of shape (n_samples,)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `pos_label` [int or str, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `drop_intermediate` [bool, default=True] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

Returns

- `fpr` [ndarray of shape (>2,)] Increasing false positive rates such that element i is the false positive rate of predictions with score >= thresholds[i].
- `tpr` [ndarray of shape (>2,)] Increasing true positive rates such that element i is the true positive rate of predictions with score >= thresholds[i].
- `thresholds` [ndarray of shape = (n_thresholds,)] Decreasing thresholds on the decision function used to compute fpr and tpr. thresholds[0] represents no instances being predicted and is arbitrarily set to max(y_score) + 1.

See also:

- `plot_roc_curve` Plot Receiver operating characteristic (ROC) curve.
- `RocCurveDisplay` ROC Curve visualization.
- `det_curve` Compute error rates for different probability thresholds.
**roc_auc_score**  Compute the area under the ROC curve.

**Notes**

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both \( \text{fpr} \) and \( \text{tpr} \), which are sorted in reversed order during their calculation.

**References**

[1], [2]

**Examples**

```python
give examples using code blocks
```
**y_score** [array-like of shape (n_samples,) or (n_samples, n_classes)] Target scores. These can be either probability estimates or non-thresholded decision values (as returned by `decision_function` on some classifiers). The binary case expects scores with shape (n_samples,) while the multiclass case expects scores with shape (n_samples, n_classes). In the multiclass case, the order of the class scores must correspond to the order of `labels`, if provided, or else to the numerical or lexicographical order of the labels in `y_true`.

**k** [int, default=2] Number of most likely outcomes considered to find the correct label.

**normalize** [bool, default=True] If True, return the fraction of correctly classified samples. Otherwise, return the number of correctly classified samples.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, all samples are given the same weight.

**labels** [array-like of shape (n_classes,), default=None] Multiclass only. List of labels that index the classes in `y_score`. If None, the numerical or lexicographical order of the labels in `y_true` is used.

**Returns**

**score** [float] The top-k accuracy score. The best performance is 1 with normalize == True and the number of samples with normalize == False.

**See also:**

`accuracy_score`

**Notes**

In cases where two or more labels are assigned equal predicted scores, the labels with the highest indices will be chosen first. This might impact the result if the correct label falls after the threshold because of that.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.metrics import top_k_accuracy_score
>>> y_true = np.array([0, 1, 2, 2])
>>> y_score = np.array([[[0.5, 0.2, 0.2],  # 0 is in top 2
...                       [0.3, 0.4, 0.2],  # 1 is in top 2
...                       [0.2, 0.4, 0.3],  # 2 is in top 2
...                       [0.7, 0.2, 0.1]]])  # 2 isn't in top 2
>>> top_k_accuracy_score(y_true, y_score, k=2)
0.75

>>> # Not normalizing gives the number of "correctly" classified samples
>>> top_k_accuracy_score(y_true, y_score, k=2, normalize=False)
3
```
Zero-one classification loss.

If normalize is True, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **normalize** [bool, default=True] If False, return the number of misclassifications. Otherwise, return the fraction of misclassifications.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **loss** [float or int] If normalize == True, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).

See also:

- accuracy_score, hamming_loss, jaccard_score

Notes

In multilabel classification, the zero_one_loss function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

Examples

```python
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

**sklearn.metrics.explained_variance_score**

```python
sklearn.metrics.explained_variance_score(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')
```

Explained variance regression score function.

Best possible score is 1.0, lower values are worse.

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [‘raw_values’, ‘uniform_average’, ‘variance_weighted’] or array-like of shape (n_outputs,), default=’uniform_average’) Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.
  - ‘raw_values’ : Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’ : Scores of all outputs are averaged with uniform weight.
‘variance_weighted’ : Scores of all outputs are averaged, weighted by the variances of each individual output.

Returns

score [float or ndarray of floats] The explained variance or ndarray if ‘multioutput’ is ‘raw_values’.

Notes

This is not a symmetric function.

Examples

```python
>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
0.983...
```

sklearn.metrics.max_error

sklearn.metrics.max_error(y_true, y_pred)

max_error metric calculates the maximum residual error.

Read more in the User Guide.

Parameters

y_true [array-like of shape (n_samples,)] Ground truth (correct) target values.

y_pred [array-like of shape (n_samples,)] Estimated target values.

Returns

max_error [float] A positive floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import max_error
>>> y_true = [3, 2, 7, 1]
>>> y_pred = [4, 2, 7, 1]
>>> max_error(y_true, y_pred)
1
```
sklearn.metrics.mean_absolute_error

sklearn.metrics.mean_absolute_error(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')

Mean absolute error regression loss.

Read more in the User Guide.

Parameters

y_true [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.

y_pred [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

multioutput [{'raw_values', 'uniform_average'} or array-like of shape (n_outputs,), default='uniform_average'] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

'raw_values' : Returns a full set of errors in case of multioutput input.

'uniform_average' : Errors of all outputs are averaged with uniform weight.

Returns

loss [float or ndarray of floats] If multioutput is 'raw_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform_average' or an ndarray of weights, then the weighted average of all output errors is returned.

MAE output is non-negative floating point. The best value is 0.0.

Examples

```python
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.0])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85...
```
Examples using `sklearn.metrics.mean_absolute_error`

- Poisson regression and non-normal loss
- Tweedie regression on insurance claims

`sklearn.metrics.mean_squared_error`

`sklearn.metrics.mean_squared_error(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average', squared=True)`

Mean squared error regression loss.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [{‘raw_values’, ‘uniform_average’} or array-like of shape (n_outputs,), default=‘uniform_average’] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - ‘raw_values’ : Returns a full set of errors in case of multioutput input.
  - ‘uniform_average’ : Errors of all outputs are averaged with uniform weight.
- `squared` [bool, default=True] If True returns MSE value, if False returns RMSE value.

Returns

- `loss` [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```python
>>> from sklearn.metrics import mean_squared_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred, squared=False)
0.612...
>>> y_true = [[0.5, 1],[-1, 1],[7, -6]]
>>> y_pred = [[0, 2],[-1, 2],[8, -5]]
>>> mean_squared_error(y_true, y_pred)
0.708...
>>> mean_squared_error(y_true, y_pred, squared=False)
0.822...
>>> mean_squared_error(y_true, y_pred, multioutput='raw_values')
array([0.41666667, 1.])
>>> mean_squared_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.825...
```
scikit-learn user guide, Release 0.24.dev0

Examples using `sklearn.metrics.mean_squared_log_error`

- Gradient Boosting regression
- Model Complexity Influence
- Plot Ridge coefficients as a function of the L2 regularization
- Linear Regression Example
- Robust linear estimator fitting
- Poisson regression and non-normal loss
- Tweedie regression on insurance claims

```
sklearn.metrics.mean_squared_log_error

```

sklearn.metrics.mean_squared_log_error(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')

Mean squared logarithmic error regression loss.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [{‘raw_values’, ‘uniform_average’} or array-like of shape (n_outputs,), default=’uniform_average’] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - ‘raw_values’ : Returns a full set of errors when the input is of multioutput format.
  - ‘uniform_average’ : Errors of all outputs are averaged with uniform weight.

Returns

- `loss` [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```python
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...
>>> y_true = [[0.5, 1], [1, 2], [7, 6]]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...
>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
array([0.00462428, 0.08377444])
>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.060...
```
sklearn.metrics.median_absolute_error

sklearn.metrics.median_absolute_error(y_true, y_pred, *, multioutput='uniform_average', sample_weight=None)

Median absolute error regression loss.

Median absolute error output is non-negative floating point. The best value is 0.0. Read more in the User Guide.

Parameters

y_true [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.

y_pred [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.

multioutput [{‘raw_values’, ‘uniform_average’} or array-like of shape (n_outputs,), default=’uniform_average’] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

‘raw_values’ : Returns a full set of errors in case of multioutput input.

‘uniform_average’ : Errors of all outputs are averaged with uniform weight.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

New in version 0.24.

Returns

loss [float or ndarray of floats] If multioutput is ‘raw_values’, then mean absolute error is returned for each output separately. If multioutput is ‘uniform_average’ or an ndarray of weights, then the weighted average of all output errors is returned.

Examples

```python
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> median_absolute_error(y_true, y_pred)
0.75
>>> median_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.])
>>> median_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85
```
Examples using `sklearn.metrics.median_absolute_error`

- Common pitfalls in interpretation of coefficients of linear models
- Effect of transforming the targets in regression model

`sklearn.metrics.mean_absolute_percentage_error`

Mean absolute percentage error regression loss.

Note here that we do not represent the output as a percentage in range \([0, 100]\). Instead, we represent it in range \([0, 1/\text{eps}]\). Read more in the User Guide.

New in version 0.24.

Parameters

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [‘raw_values’, ‘uniform_average’ or array-like] Defines aggregating of multiple output values. Array-like value defines weights used to average errors. If input is list then the shape must be (n_outputs,).
  - ‘raw_values’: Returns a full set of errors in case of multioutput input.
  - ‘uniform_average’: Errors of all outputs are averaged with uniform weight.

Returns

- `loss` [float or ndarray of floats in the range \([0, 1/\text{eps}]\)] If multioutput is ‘raw_values’, then mean absolute percentage error is returned for each output separately. If multioutput is ‘uniform_average’ or an ndarray of weights, then the weighted average of all output errors is returned.

MAPE output is non-negative floating point. The best value is 0.0. But note the fact that bad predictions can lead to arbitrarily large MAPE values, especially if some `y_true` values are very close to zero. Note that we return a large value instead of `inf` when `y_true` is zero.

Examples

```python
>>> from sklearn.metrics import mean_absolute_percentage_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_percentage_error(y_true, y_pred)
0.3273...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_percentage_error(y_true, y_pred)
0.5515...
>>> mean_absolute_percentage_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.6198...
```
**sklearn.metrics.r2_score**

```python
sklearn.metrics.r2_score(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')
```

R^2 (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Read more in the User Guide.

**Parameters**

- **y_true** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- **y_pred** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **multioutput** [{'raw_values', 'uniform_average', 'variance_weighted'}, array-like of shape (n_outputs,) or None, default='uniform_average'] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is “uniform_average”.
  - ‘raw_values’ : Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’ : Scores of all outputs are averaged with uniform weight.
  - ‘variance_weighted’ : Scores of all outputs are averaged, weighted by the variances of each individual output.

Changed in version 0.19: Default value of multioutput is ‘uniform_average’.

**Returns**

- **z** [float or ndarray of floats] The R^2 score or ndarray of scores if ‘multioutput’ is ‘raw_values’.

**Notes**

This is not a symmetric function.

Unlike most other scores, R^2 score may be negative (it need not actually be the square of a quantity R).

This metric is not well-defined for single samples and will return a NaN value if n_samples is less than two.

**References**

[1]
Examples

```python
>>> from sklearn.metrics import r2_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred, multioutput='variance_weighted')
0.938...
>>> y_true = [1, 2, 3]
>>> y_pred = [1, 2, 3]
>>> r2_score(y_true, y_pred)
1.0
>>> y_true = [1, 2, 3]
>>> y_pred = [2, 2, 2]
>>> r2_score(y_true, y_pred)
0.0
>>> y_true = [3, 2, 1]
>>> y_pred = [3, 2, 1]
>>> r2_score(y_true, y_pred)
-3.0
```

Examples using sklearn.metrics.r2_score

- Non-negative least squares
- Linear Regression Example
- Lasso and Elastic Net for Sparse Signals
- Effect of transforming the targets in regression model

sklearn.metrics.mean_poisson_deviance

**sklearn.metrics.mean_poisson_deviance(y_true, y_pred, *, sample_weight=None)**

Mean Poisson deviance regression loss.

Poisson deviance is equivalent to the Tweedie deviance with the power parameter power=1.

Read more in the *User Guide*.

**Parameters**

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values. Requires `y_true >= 0`.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values. Requires `y_pred > 0`.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `loss` [float] A non-negative floating point value (the best value is 0.0).
Examples

```python
>>> from sklearn.metrics import mean_poisson_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_poisson_deviance(y_true, y_pred)
1.4260...
```

Examples using `sklearn.metrics.mean_poisson_deviance`

- Poisson regression and non-normal loss

`sklearn.metrics.mean_gamma_deviance`

```python
sklearn.metrics.mean_gamma_deviance(y_true, y_pred, *, sample_weight=None)
Mean Gamma deviance regression loss.

Gamma deviance is equivalent to the Tweedie deviance with the power parameter `power=2`. It is invariant to scaling of the target variable, and measures relative errors.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values. Requires `y_true > 0`.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values. Requires `y_pred > 0`.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- `loss` [float] A non-negative floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import mean_gamma_deviance
>>> y_true = [2, 0.5, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_gamma_deviance(y_true, y_pred)
1.0568...
```

`sklearn.metrics.mean_tweedie_deviance`

```python
sklearn.metrics.mean_tweedie_deviance(y_true, y_pred, *, sample_weight=None, power=0)
Mean Tweedie deviance regression loss.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Examples

```python
>>> from sklearn.metrics import mean_tweedie_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_tweedie_deviance(y_true, y_pred)
1.0026...
```
power  [float, default=0] Tweedie power parameter. Either power <= 0 or power >= 1.

The higher $p$ the less weight is given to extreme deviations between true and predicted targets.

- power < 0: Extreme stable distribution. Requires: $y_{\text{pred}} > 0$.
- power = 0: Normal distribution, output corresponds to mean_squared_error. $y_{\text{true}}$ and $y_{\text{pred}}$ can be any real numbers.
- power = 1: Poisson distribution. Requires: $y_{\text{true}} \geq 0$ and $y_{\text{pred}} > 0$.
- $1 < p < 2$: Compound Poisson distribution. Requires: $y_{\text{true}} \geq 0$ and $y_{\text{pred}} > 0$.
- power = 2: Gamma distribution. Requires: $y_{\text{true}} > 0$ and $y_{\text{pred}} > 0$.
- power = 3: Inverse Gaussian distribution. Requires: $y_{\text{true}} > 0$ and $y_{\text{pred}} > 0$.
- otherwise: Positive stable distribution. Requires: $y_{\text{true}} > 0$ and $y_{\text{pred}} > 0$.

Returns

loss  [float] A non-negative floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import mean_tweedie_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_tweedie_deviance(y_true, y_pred, power=1)
1.4260...
```

Examples using sklearn.metrics.mean_tweedie_deviance

- Tweedie regression on insurance claims

7.24.4 Multilabel ranking metrics

See the Multilabel ranking metrics section of the user guide for further details.

```python
metrics.coverage_error(y_true, y_score, *[, ]
metrics.label_ranking_average_precision_score(. . . ) Compute ranking-based average precision.
metrics.label_ranking_loss(y_true,
metrics.label_ranking_loss(y_true, y_score, *)
```
**sklearn.metrics.coverage_error**

`sklearn.metrics.coverage_error(y_true, y_score, *, sample_weight=None)`  
Coverage error measure.  
Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in `y_true` per sample.  
Ties in `y_scores` are broken by giving maximal rank that would have been assigned to all tied values.  
Note: Our implementation’s score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.  
Read more in the User Guide.

**Parameters**

- `y_true` [ndarray of shape (n_samples, n_labels)] True binary labels in binary indicator format.  
- `y_score` [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).  
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `coverage_error` [float]

**References**

[1]

**sklearn.metrics.label_ranking_average_precision_score**

`sklearn.metrics.label_ranking_average_precision_score(y_true, y_score, *, sample_weight=None)`  
Compute ranking-based average precision.  
Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.  
This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.  
The obtained score is always strictly greater than 0 and the best value is 1.  
Read more in the User Guide.

**Parameters**

- `y_true` [{ndarray, sparse matrix} of shape (n_samples, n_labels)] True binary labels in binary indicator format.  
- `y_score` [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).  
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.  

New in version 0.20.

**Returns**
score [float]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

**sklearn.metrics.label_ranking_loss**

`sklearn.metrics.label_ranking_loss(y_true, y_score, *, sample_weight=None)`

Compute Ranking loss measure.

- Compute the average number of label pairs that are incorrectly ordered given `y_score` weighted by the size of the label set and the number of labels not in the label set.
- This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.
- Read more in the User Guide.

New in version 0.17: A function `label_ranking_loss`

Parameters

- `y_true` [ndarray, sparse matrix] of shape (n_samples, n_labels)] True binary labels in binary indicator format.
- `y_score` [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `sample_weight` [array-like of shape (n_samples,], default=None] Sample weights.

Returns

- `loss` [float]

References

[1]

7.24.5 Clustering metrics

See the Clustering performance evaluation section of the user guide for further details.

The `sklearn.metrics.cluster` submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the ‘quality’ of the model itself.
Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings $U$ and $V$, the AMI is given as:

$$\text{AMI}(U, V) = \frac{\text{MI}(U, V) - E(\text{MI}(U, V))}{\text{avg}(H(U), H(V)) - E(\text{MI}(U, V))}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching label_true with label_pred will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the User Guide.

**Parameters**

- **labels_true** [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- **labels_pred** [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.
average_method (str, default='arithmetic') How to compute the normalizer in the denominator. Possible options are ‘min’, ‘geometric’, ‘arithmetic’, and ‘max’.

New in version 0.20.

Changed in version 0.22: The default value of average_method changed from ‘max’ to ‘arithmetic’.

Returns

ami: float (upperlimited by 1.0) The AMI returns a value of 1 when the two partitions are identical (ie perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

See also:

adjusted_rand_score Adjusted Rand Index.
mutual_info_score Mutual Information (not adjusted for chance).

References

[1], [2]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the AMI is null:

```python
>>> adjusted_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

Examples using sklearn.metrics.adjusted_mutual_info_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
sklearn.metrics.adjusted_rand_score

sklearn.metrics.adjusted_rand_score(labels_true, labels_pred)

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then “adjusted for chance” into the ARI score using the following scheme:

\[
ARI = \frac{RI - \text{Expected}_RI}{\text{max}(RI) - \text{Expected}_RI}
\]

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

\[
\text{adjusted_rand_score}(a, b) == \text{adjusted_rand_score}(b, a)
\]

Read more in the User Guide.

Parameters

labels_true [int array, shape = [n_samples]] Ground truth class labels to be used as a reference

labels_pred [array-like of shape (n_samples,)] Cluster labels to evaluate

Returns

ari [float] Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

See also:

adjusted_mutual_info_score Adjusted Mutual Information.

References

[Hubert1985], [wk]

Examples

Perfectly matching labelings have a score of 1 even

```python
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete be not always pure, hence penalized:

```python
>>> adjusted_rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.57...
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 2])
0.57...

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0

Examples using `sklearn.metrics.adjusted_rand_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`sklearn.metrics.calinski_harabasz_score`

`sklearn.metrics.calinski_harabasz_score(X, labels)`
Compute the Calinski and Harabasz score.

- It is also known as the Variance Ratio Criterion.
- The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.
- Read more in the User Guide.

**Parameters**

- `X`  [array-like of shape (n_samples, n_features)] A list of n_features-dimensional data points. Each row corresponds to a single data point.
- `labels`  [array-like of shape (n_samples,)] Predicted labels for each sample.

**Returns**

- `score`  [float] The resulting Calinski-Harabasz score.

**References**

- [1]
sklearn.metrics.davies_bouldin_score

sklearn.metrics.davies_bouldin_score(X, labels)
Computes the Davies-Bouldin score.

The score is defined as the average similarity measure of each cluster with its most similar cluster, where similarity is the ratio of within-cluster distances to between-cluster distances. Thus, clusters which are farther apart and less dispersed will result in a better score.

The minimum score is zero, with lower values indicating better clustering.

Read more in the User Guide.

New in version 0.20.

Parameters

X [array-like of shape (n_samples, n_features)] A list of n_features-dimensional data points. Each row corresponds to a single data point.

labels [array-like of shape (n_samples,)] Predicted labels for each sample.

Returns

score: float The resulting Davies-Bouldin score.

References

[1]

sklearn.metrics.completeness_score

sklearn.metrics.completeness_score(labels_true, labels_pred)
Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is not symmetric: switching label_true with label_pred will return the homogeneity_score which will be different in general.

Read more in the User Guide.

Parameters

labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference

labels_pred [array-like of shape (n_samples,)] cluster labels to evaluate

Returns

completeness [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

homogeneity_score

v_measure_score
References

[1]

Examples

Perfect labelings are complete:

```python
>>> from sklearn.metrics.cluster import completeness_score
>>> completeness_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that assign all classes members to the same clusters are still complete:

```python
>>> print(completeness_score([0, 0, 1, 1], [0, 0, 0, 0]))
1.0
>>> print(completeness_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.999...
```

If classes members are split across different clusters, the assignment cannot be complete:

```python
>>> print(completeness_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0
>>> print(completeness_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0
```

Examples using sklearn.metrics.completeness_score

- Release Highlights for scikit-learn 0.23
- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

sklearn.metrics.cluster.contingency_matrix

```
sklearn.metrics.cluster.contingency_matrix(labels_true, labels_pred, *, eps=None, sparse=False)
```

Build a contingency matrix describing the relationship between labels.

Parameters

- `labels_true` [int array, shape = [n_samples]] Ground truth class labels to be used as a reference
- `labels_pred` [array-like of shape (n_samples,)] Cluster labels to evaluate
- `eps` [float, default=None] If a float, that value is added to all values in the contingency matrix. This helps to stop NaN propagation. If None, nothing is adjusted.
- `sparse` [bool, default=False] If True, return a sparse CSR continency matrix. If eps is not None, and sparse is True, will throw ValueError.

New in version 0.18.
Returns

contingency [{array-like, sparse}, shape=[n_classes_true, n_classes_pred]] Matrix $C$ such that $C_{i,j}$ is the number of samples in true class $i$ and in predicted class $j$. If `eps` is None, the dtype of this array will be integer. If `eps` is given, the dtype will be float. Will be a scipy.sparse.csr_matrix if `sparse=True`.

sklearn.metrics.fowlkes_mallows_score

sklearn.metrics.fowlkes_mallows_score (labels_true, labels_pred, *, sparse=False)

Measure the similarity of two clusterings of a set of points.

New in version 0.18.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between of the precision and recall:

$$FMI = \frac{TP}{\sqrt{(TP + FP) \times (TP + FN)}}$$

Where $TP$ is the number of True Positive (i.e. the number of pair of points that belongs in the same clusters in both `labels_true` and `labels_pred`), $FP$ is the number of False Positive (i.e. the number of pair of points that belongs in the same clusters in `labels_true` and not in `labels_pred`) and $FN$ is the number of False Negative (i.e the number of pair of points that belongs in the same clusters in `labels_pred` and not in `labels_true`).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the User Guide.

Parameters

labels_true [int array, shape = (n_samples,)] A clustering of the data into disjoint subsets.

labels_pred [array, shape = (n_samples,)] A clustering of the data into disjoint subsets.

sparse [bool, default=False] Compute contingency matrix internally with sparse matrix.

Returns

score [float] The resulting Fowlkes-Mallows score.

References

[1], [2]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> fowlkes_mallows_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:
```python
>>> fowlkes_mallows_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

**sklearn.metrics.homogeneity_completeness_v_measure**

```python
sklearn.metrics.homogeneity_completeness_v_measure(labels_true, labels_pred, *, beta=1.0)
```

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score values in any way.

V-Measure is furthermore symmetric: swapping `labels_true` and `labels_pred` will give the same score. This does not hold for homogeneity and completeness. V-Measure is identical to `normalized_mutual_info_score` with the arithmetic averaging method.

Read more in the User Guide.

**Parameters**

- **labels_true** [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- **labels_pred** [array-like of shape (n_samples,)] cluster labels to evaluate
- **beta** [float, default=1.0] Ratio of weight attributed to homogeneity vs completeness. If `beta` is greater than 1, completeness is weighted more strongly in the calculation. If `beta` is less than 1, homogeneity is weighted more strongly.

**Returns**

- **homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling
- **completeness** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling
- **v_measure** [float] harmonic mean of the first two

**See also:**

- `homogeneity_score`
- `completeness_score`
- `v_measure_score`
**sklearn.metrics.homogeneity_score**

`sklearn.metrics.homogeneity_score(labels_true, labels_pred)`

Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is not symmetric: switching `label_true` with `label_pred` will return the `completeness_score` which will be different in general.

Read more in the *User Guide.*

**Parameters**

- `labels_true` [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- `labels_pred` [array-like of shape (n_samples,)] cluster labels to evaluate

**Returns**

- `homogeneity` [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

**See also:**

- `completeness_score`
- `v_measure_score`

**References**

[1]

**Examples**

Perfect labelings are homogeneous:

```python
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
1.000000
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
1.000000
```

Clusters that include samples from different classes do not make for an homogeneous labeling:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```
Examples using `sklearn.metrics.homogeneity_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`sklearn.metrics.mutual_info_score`

```python
sklearn.metrics.mutual_info_score(labels_true, labels_pred, *, contingency=None)
```

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where \(|U_i|\) is the number of the samples in cluster \(U_i\) and \(|V_j|\) is the number of the samples in cluster \(V_j\), the Mutual Information between clusterings \(U\) and \(V\) is given as:

\[
MI(U, V) = \sum_{i=1}^{U} \sum_{j=1}^{V} \frac{|U_i \cap V_j|}{N} \log \frac{N|U_i \cap V_j|}{|U_i||V_j|}
\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `labels_pred` [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.
- `contingency` [{ndarray, sparse matrix} of shape (n_classes_true, n_classes_pred), default=None] A contingency matrix given by the `contingency_matrix` function. If value is None, it will be computed, otherwise the given value is used, with `labels_true` and `labels_pred` ignored.

**Returns**

- `mi` [float] Mutual information, a non-negative value

**See also:**

- `adjusted_mutual_info_score` Adjusted against chance Mutual Information.
- `normalized_mutual_info_score` Normalized Mutual Information.
Notes
The logarithm used is the natural logarithm (base-e).

Examples using sklearn.metrics.mutual_info_score

• Adjustment for chance in clustering performance evaluation

sklearn.metrics.normalized_mutual_info_score

sklearn.metrics.normalized_mutual_info_score(labels_true, labels_pred, *, average_method='arithmetic')

Normalized Mutual Information between two clusterings.

Normalized Mutual Information (NMI) is a normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by some generalized mean of $H(labels_true)$ and $H(labels_pred)$, defined by the average_method.

This measure is not adjusted for chance. Therefore adjusted_mutual_info_score might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching label_true with label_pred will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

Parameters

labels_true [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.

labels_pred [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.

average_method [str, default='arithmetic'] How to compute the normalizer in the denominator.

Possible options are ‘min’, ‘geometric’, ‘arithmetic’, and ‘max’.

New in version 0.20.

Changed in version 0.22: The default value of average_method changed from ‘geometric’ to ‘arithmetic’.

Returns

nmi [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

v_measure_score V-Measure (NMI with arithmetic mean option).

adjusted_rand_score Adjusted Rand Index.

adjusted_mutual_info_score Adjusted Mutual Information (adjusted against chance).
Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the NMI is null:

```python
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

**sklearn.metrics.silhouette_score**

`sklearn.metrics.silhouette_score(X, labels, *, metric='euclidean', sample_size=None, random_state=None, **kwds)`

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (a) and the mean nearest-cluster distance (b) for each sample. The Silhouette Coefficient for a sample is \((b - a) / \max(a, b)\). To clarify, \(b\) is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficient is only defined if number of labels is \(2 <= n_labels <= n_samples - 1\).

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use `silhouette_samples`.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the `User Guide`.

**Parameters**

- **X** [array-like of shape (n_samples_a, n_samples_a) if metric == “precomputed” or (n_samples_a, n_features) otherwise] An array of pairwise distances between samples, or a feature array.

- **labels** [array-like of shape (n_samples,)] Predicted labels for each sample.

- **metric** [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `metrics.pairwise.pairwise_distances`. If X is the distance array itself, use metric="precomputed".

- **sample_size** [int, default=None] The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If sample_size is None, no sampling is used.

- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for selecting a subset of samples. Used when sample_size is not None. Pass an int for reproducible results across multiple function calls. See Glossary.
**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scppy.spatial.distance metric, the parameters are still metric dependent. See the scppy docs for usage examples.

Returns

silhouette [float] Mean Silhouette Coefficient for all samples.

References

[1], [2]

Examples using sklearn.metrics.silhouette_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Selecting the number of clusters with silhouette analysis on KMeans clustering
- Clustering text documents using k-means

sklearn.metrics.silhouette_samples

sklearn.metrics.silhouette_samples(X, labels, *, metric='euclidean', **kwds)

Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance \( a \) and the mean nearest-cluster distance \( b \) for each sample. The Silhouette Coefficient for a sample is \( \frac{b - a}{\max(a, b)} \). Note that Silhouette Coefficient is only defined if number of labels is \( 2 \leq n\_labels \leq n\_samples - 1 \).

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

Read more in the User Guide.

Parameters

- **X** [array-like of shape \( (n\_samples_a, n\_samples_a) \) if metric == “precomputed” or \( (n\_samples_a, n\_features) \) otherwise] An array of pairwise distances between samples, or a feature array.
- **labels** [array-like of shape \( (n\_samples,) \)] Label values for each sample.
- **metric** [str or callable, default=’euclidean’] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by sklearn.metrics.pairwise.pairwise_distances. If X is the distance array itself, use “precomputed” as the metric. Precomputed distance matrices must have 0 along the diagonal.
**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns

silhouette [array-like of shape (n_samples,)] Silhouette Coefficients for each sample.

References

[1], [2]

Examples using sklearn.metrics.silhouette_samples

- Selecting the number of clusters with silhouette analysis on KMeans clustering

sklearn.metrics.v_measure_score

sklearn.metrics.v_measure_score(labels_true, labels_pred, *, beta=1.0)

V-measure cluster labeling given a ground truth.

This score is identical to normalized_mutual_info_score with the 'arithmetic' option for averaging.

The V-measure is the harmonic mean between homogeneity and completeness:

\[
v = \frac{(1 + \beta) \times \text{homogeneity} \times \text{completeness}}{\beta \times \text{homogeneity} + \text{completeness}}
\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching label_true with label_pred will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

Parameters

labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference

labels_pred [array-like of shape (n_samples,)] cluster labels to evaluate

beta [float, default=1.0] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

Returns

v_measure [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

homogeneity_score
completeness_score
normalized_mutual_info_score
References

[1]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not homogeneous, hence penalized:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.66...
```

Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```python
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```

Examples using `sklearn.metrics.v_measure_score`

- Biclustering documents with the Spectral Co-clustering algorithm

7.24.6 Biclustering metrics

See the Biclustering evaluation section of the user guide for further details.

```python
metrics.consensus_score(a, b, *, similarity)  # The similarity of two sets of biclusters.
```

```python
sklearn.metrics.consensus_score(a, b, *, similarity='jaccard')

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the User Guide.
```

Parameters

- `a` [(rows, columns)] Tuple of row and column indicators for a set of biclusters.
- `b` [(rows, columns)] Another set of biclusters like `a`.
- `similarity` ['jaccard' or callable, default='jaccard'] May be the string “jaccard” to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a_rows, a_columns, b_rows, b_columns).

7.24.7 Pairwise metrics

See the Pairwise metrics, Affinities and Kernels section of the user guide for further details.

```python
metrics.pairwise.additive_chi2_kernel(X, Y)  # Computes the additive chi-squared kernel between observations in X and Y.
metrics.pairwise.chi2_kernel(X, Y, gamma)  # Computes the exponential chi-squared kernel X and Y.
metrics.pairwise.cosine_similarity(X, Y, ...)  # Compute cosine similarity between samples in X and Y.
metrics.pairwise.cosine_distances(X, Y)  # Compute cosine distance between samples in X and Y.
metrics.pairwise.distance_metrics()  # Valid metrics for pairwise_distances.
metrics.pairwise.euclidean_distances(X, Y, ...)  # Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.
```

continues on next page
sklearn.metrics.pairwise.additive_chi2_kernel

Computes the additive chi-squared kernel between observations in X and Y.

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

\[ k(x, y) = -\sum \frac{(x - y)^2}{x + y} \]

It can be interpreted as a weighted difference per entry.

Read more in the User Guide.
X [array-like of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]

Returns
kernel_matrix [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

chi2_kernel The exponentiated version of the kernel, which is usually preferable.
sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to this kernel.

Notes
As the negative of a distance, this kernel is only conditionally positive definite.

References

sklearn.metrics.pairwise.chi2_kernel

sklearn.metrics.pairwise.chi2_kernel(X, Y=None, gamma=1.0)
Computes the exponential chi-squared kernel X and Y.
The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative.
This kernel is most commonly applied to histograms.
The chi-squared kernel is given by:
\[ k(x, y) = \exp(-\gamma \text{Sum} [(x - y)^2 / (x + y)]) \]
It can be interpreted as a weighted difference per entry.
Read more in the User Guide.

Parameters
X [array-like of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]
gamma [float, default=1.0] Scaling parameter of the chi2 kernel.

Returns
kernel_matrix [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

additive_chi2_kernel The additive version of this kernel.
sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to the additive version of this kernel.
References

sklearn.metrics.pairwise.cosine_similarity

```
sklearn.metrics.pairwise.cosine_similarity(X, Y=None, dense_output=True)
```

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

\[ K(X, Y) = \frac{<X, Y>}{\|X\| * \|Y\|} \]

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the User Guide.

Parameters

- `X` [ndarray, sparse matrix] of shape (n_samples_X, n_features) Input data.
- `Y` [ndarray, sparse matrix] of shape (n_samples_Y, n_features), default=None Input data. If None, the output will be the pairwise similarities between all samples in X.
- `dense_output` [bool, default=True] Whether to return dense output even when the input is sparse. If False, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter `dense_output` for dense output.

Returns

- `kernel matrix` [ndarray of shape (n_samples_X, n_samples_Y)]

sklearn.metrics.pairwise.cosine_distances

```
sklearn.metrics.pairwise.cosine_distances(X, Y=None)
```

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the User Guide.

Parameters

- `X` [array-like, sparse matrix] of shape (n_samples_X, n_features) Matrix X.
- `Y` [array-like, sparse matrix] of shape (n_samples_Y, n_features), default=None Matrix Y.

Returns

- `distance matrix` [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

- `cosine_similarity`
- `scipy.spatial.distance.cosine` Dense matrices only.
sklearn.metrics.pairwise.distance_metrics

Valid metrics for pairwise_distances.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cityblock'</td>
<td>metrics.pairwise.manhattan_distances</td>

<td>metrics.pairwise.nan_euclidean_distances</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

sklearn.metrics.pairwise.euclidean_distances

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:

\[
\text{dist}(x, y) = \sqrt{\text{dot}(x, x) - 2 \times \text{dot}(x, y) + \text{dot}(y, y)}
\]

This formulation has two advantages over other ways of computing distances. First, it is computationally efficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then \(\text{dot}(x, x)\) and/or \(\text{dot}(y, y)\) can be pre-computed.

However, this is not the most precise way of doing this computation, because this equation potentially suffers from “catastrophic cancellation”. Also, the distance matrix returned by this function may not be exactly symmetric as required by, e.g., scipy.spatial.distance functions.

Parameters

- **X** [{array-like, sparse matrix} of shape (n_samples_X, n_features)]
- **Y** [{array-like, sparse matrix} of shape (n_samples_Y, n_features), default=None]
- **Y_norm_squared** [array-like of shape (n_samples_Y,), default=None] Pre-computed dot-products of vectors in Y (e.g., \(Y**2\).sum(axis=1)) May be ignored in some cases, see the note below.
- **squared** [bool, default=False] Return squared Euclidean distances.
- **X_norm_squared** [array-like of shape (n_samples,), default=None] Pre-computed dot-products of vectors in X (e.g., \(X**2\).sum(axis=1)) May be ignored in some cases, see the note below.

Returns
**distances** [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

**paired_distances** Distances between pairs of elements of X and Y.

**Notes**

To achieve better accuracy, X_norm_squared and Y_norm_squared may be unused if they are passed as float32.

**Examples**

```python
>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[0., 1.],
       [1., 0.]])
>>> # get distance to origin
>>> euclidean_distances(X, [[0, 0]])
array([[1.],
       [1.41421356]])
```

**sklearn.metrics.pairwise.haversine_distances**

**sklearn.metrics.pairwise.haversine_distances(X, Y=None)**

Compute the Haversine distance between samples in X and Y.

The Haversine (or great circle) distance is the angular distance between two points on the surface of a sphere. The first coordinate of each point is assumed to be the latitude, the second is the longitude, given in radians. The dimension of the data must be 2.

\[ D(x, y) = 2 \arcsin\left(\sqrt{\sin^2((x_1 - y_1)/2) + \cos(x_1)\cos(y_1)\sin^2((x_2 - y_2)/2)}\right) \]

**Parameters**

- **X** [array-like of shape (n_samples_X, 2)]
- **Y** [array-like of shape (n_samples_Y, 2), default=None]

**Returns**

- **distance** [ndarray of shape (n_samples_X, n_samples_Y)]

**Notes**

As the Earth is nearly spherical, the haversine formula provides a good approximation of the distance between two points of the Earth surface, with a less than 1% error on average.
Examples

We want to calculate the distance between the Ezeiza Airport (Buenos Aires, Argentina) and the Charles de Gaulle Airport (Paris, France).

```python
>>> from sklearn.metrics.pairwise import haversine_distances
>>> from math import radians

>>> bsas = [-34.83333, -58.5166646]
>>> paris = [49.0083899664, 2.53844117956]
>>> bsas_in_radians = [radians(_) for _ in bsas]
>>> paris_in_radians = [radians(_) for _ in paris]
>>> result = haversine_distances([bsas_in_radians, paris_in_radians])
>>> result * 6371000/1000  # multiply by Earth radius to get kilometers
array([[ 0. , 11099.54035582],
       [11099.54035582,  0. ]])
```

**sklearn.metrics.pairwise.kernel_metrics**

**sklearn.metrics.pairwise.kernel_metrics()**

Valid metrics for pairwise_kernels.

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>
<thead>
<tr>
<th>metric</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'additive_chi2'</td>
<td>sklearn.pairwise.additive_chi2_kernel</td>
</tr>
<tr>
<td>'chi2'</td>
<td>sklearn.pairwise.chi2_kernel</td>
</tr>
<tr>
<td>'linear'</td>
<td>sklearn.pairwise.linear_kernel</td>
</tr>
<tr>
<td>'poly'</td>
<td>sklearn.pairwise.polynomial_kernel</td>
</tr>
<tr>
<td>'polynomial'</td>
<td>sklearn.pairwise.polynomial_kernel</td>
</tr>
<tr>
<td>'rbf'</td>

<td>sklearn.pairwise.laplacian_kernel</td>
</tr>
<tr>
<td>'sigmoid'</td>
<td>sklearn.pairwise.sigmoid_kernel</td>
</tr>
<tr>
<td>'cosine'</td>
<td>sklearn.pairwise.cosine_similarity</td>
</tr>
</tbody>
</table>

Read more in the *User Guide*.

**sklearn.metrics.pairwise.laplacian_kernel**

**sklearn.metrics.pairwise.laplacian_kernel(X, Y=None, gamma=None)**

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

\[
K(x, y) = \exp(-\gamma ||x-y||_1)
\]

for each pair of rows x in X and y in Y. Read more in the *User Guide*.

New in version 0.17.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]

gamma [float, default=None] If None, defaults to 1.0 / n_features.

Returns

kernel_matrix [ndarray of shape (n_samples_X, n_samples_Y)]

sklearn.metrics.pairwise.linear_kernel

sklearn.metrics.pairwise.linear_kernel (X, Y=None, dense_output=True)
Compute the linear kernel between X and Y.

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]

dense_output [bool, default=True] Whether to return dense output even when the input is
sparse. If False, the output is sparse if both input arrays are sparse.

New in version 0.20.

Returns

Gram matrix [ndarray of shape (n_samples_X, n_samples_Y)]

sklearn.metrics.pairwise.manhattan_distances

sklearn.metrics.pairwise.manhattan_distances (X, Y=None, *, sum_over_features=True)
Compute the L1 distances between the vectors in X and Y.

With sum_over_features equal to False it returns the componentwise distances.

Read more in the User Guide.

Parameters

X [array-like of shape (n_samples_X, n_features)]
Y [array-like of shape (n_samples_Y, n_features), default=None]

sum_over_features [bool, default=True] If True the function returns the pairwise distance ma-
trix else it returns the componentwise L1 pairwise-distances. Not supported for sparse ma-
trix inputs.

Returns

D [ndarray of shape (n_samples_X * n_samples_Y, n_features) or (n_samples_X, n_samples_Y)] If sum_over_features is False shape is (n_samples_X * n_samples_Y, n_features) and D contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n_samples_X, n_samples_Y) and D contains the pairwise L1 distances.
Notes

When X and/or Y are CSR sparse matrices and they are not already in canonical format, this function modifies
them in-place to make them canonical.

Examples

```python
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[3]], [[3]])
array([[0.]])
>>> manhattan_distances([[3]], [[2]])
array([[1.]])
>>> manhattan_distances([[2]], [[3]])
array([[1.]])
>>> manhattan_distances([[1, 2], [3, 4]], [[1, 2], [0, 3]])
array([[0., 2.],
       [1., 1.]])
```

```
>>> X = np.ones((1, 2))
>>> y = np.full((2, 2), 2.)
>>> manhattan_distances(X, y, sum_over_features=False)
array([[1., 1.],
       [1., 1.]])
```

sklearn.metrics.pairwise.nan_euclidean_distances

Calculate the euclidean distances in the presence of missing values.

Compute the euclidean distance between each pair of samples in X and Y, where Y=X is assumed if Y=None. When calculating the distance between a pair of samples, this formulation ignores feature coordinates with a
missing value in either sample and scales up the weight of the remaining coordinates:

\[ \text{dist}(x,y) = \sqrt{\text{weight} \times \text{sq. distance from present coordinates}} \]

where, weight = Total # of coordinates / # of present coordinates

For example, the distance between \[3, na, na, 6\] and \[1, na, 4, 5\] is:

\[\sqrt{4 \times ((3 - 1)^2 + (6 - 5)^2)}\]

If all the coordinates are missing or if there are no common present coordinates then NaN is returned for that pair.

Read more in the User Guide.

New in version 0.22.

Parameters

- **X** [array-like of shape=(n_samples_X, n_features)]
- **Y** [array-like of shape=(n_samples_Y, n_features), default=None]
- **squared** [bool, default=False] Return squared Euclidean distances.
missing_values [np.nan or int, default=np.nan] Representation of missing value.

copy [bool, default=True] Make and use a deep copy of X and Y (if Y exists).

Returns
distances [ndarray of shape (n_samples_X, n_samples_Y)]

See also:
paired_distances Distances between pairs of elements of X and Y.

References

Examples

```python
gap copy

>>> from sklearn.metrics.pairwise import nan_euclidean_distances
>>> nan = float("NaN")
>>> X = [[0, 1], [1, nan]]
>>> nan_euclidean_distances(X, X) # distance between rows of X
array([[0. , 1.41421356],
       [1.41421356, 0. ]])

>>> # get distance to origin
>>> nan_euclidean_distances(X, [[0, 0]])
array([[1. ],
       [1.41421356]])
```

sklearn.metrics.pairwise.pairwise_kernels

sklearn.metrics.pairwise.pairwise_kernels(X, Y=None, metric='linear', *, filter_params=False, n_jobs=None, **kwds)

Compute the kernel between arrays X and optional array Y.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise kernel between the arrays from both X and Y.

Read more in the User Guide.

Parameters

- X [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_features)] Array of pairwise kernels between samples, or a feature array. The shape of the array should be
(n_samples_X, n_samples_X) if metric == “precomputed” and (n_samples_X, n_features) otherwise.

Y [ndarray of shape (n_samples_Y, n_features), default=None] A second feature array only if X has shape (n_samples_X, n_features).

metric [str or callable, default=”linear”] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pair-wise.PAIRWISE_KERNEL_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two rows from X as input and return the corresponding kernel value as a single number. This means that callables from sklearn.metrics.pairwise are not allowed, as they operate on matrices, not single samples. Use the string identifying the kernel instead.

filter_params [bool, default=False] Whether to filter invalid parameters or not.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**kwds [optional keyword parameters] Any further parameters are passed directly to the kernel function.

Returns

K [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_samples_Y)] A kernel matrix K such that K_[i, j] is the kernel between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then K_[i, j] is the kernel between the ith array from X and the jth array from Y.

Notes

If metric is ‘precomputed’, Y is ignored and X is returned.

sklearn.metrics.pairwise.polynomial_kernel

sklearn.metrics.pairwise.polynomial_kernel(X, Y=None, degree=3, gamma=None, coef0=1)

Compute the polynomial kernel between X and Y:

\[ K(X, Y) = (\gamma \langle X, Y \rangle + \text{coef0})^\text{degree} \]

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples_X, n_features)]

Y [ndarray of shape (n_samples_Y, n_features), default=None]

degree [int, default=3]

gamma [float, default=None] If None, defaults to 1.0 / n_features.

coef0 [float, default=1]

Returns
**Gram matrix**  [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.rbf_kernel**

`sklearn.metrics.pairwise.rbf_kernel(X, Y=None, gamma=None)`  
Computes the rbf (gaussian) kernel between X and Y:

$$K(x, y) = \exp(-\gamma \|x-y\|^2)$$

for each pair of rows x in X and y in Y.

Read more in the *User Guide*.

**Parameters**

- `X`  [ndarray of shape (n_samples_X, n_features)]
- `Y`  [ndarray of shape (n_samples_Y, n_features), default=None]
- `gamma`  [float, default=None] If None, defaults to 1.0 / n_features.

**Returns**

- `kernel_matrix`  [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.sigmoid_kernel**

`sklearn.metrics.pairwise.sigmoid_kernel(X, Y=None, gamma=None, coef0=1)`  
Computes the sigmoid kernel between X and Y:

$$K(X, Y) = \tanh(\gamma <X, Y> + \text{coef0})$$

Read more in the *User Guide*.

**Parameters**

- `X`  [ndarray of shape (n_samples_X, n_features)]
- `Y`  [ndarray of shape (n_samples_Y, n_features), default=None]
- `gamma`  [float, default=None] If None, defaults to 1.0 / n_features.
- `coef0`  [float, default=1]

**Returns**

- Gram matrix  [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.paired_euclidean_distances**

`sklearn.metrics.pairwise.paired_euclidean_distances(X, Y)`  
Computes the paired euclidean distances between X and Y.

Read more in the *User Guide*.

**Parameters**

- `X`  [array-like of shape (n_samples, n_features)]
- `Y`  [array-like of shape (n_samples, n_features)]

**Returns**
sklearn.metrics.pairwise.paired_manhattan_distances

`sklearn.metrics.pairwise.paired_manhattan_distances(X, Y)`

Computes the L1 distances between the vectors in X and Y.

Parameters

- X [array-like of shape (n_samples, n_features)]
- Y [array-like of shape (n_samples, n_features)]

Returns

- distances [ndarray of shape (n_samples,)]

sklearn.metrics.pairwise.paired_cosine_distances

`sklearn.metrics.pairwise.paired_cosine_distances(X, Y)`

Computes the paired cosine distances between X and Y.

Parameters

- X [array-like of shape (n_samples, n_features)]
- Y [array-like of shape (n_samples, n_features)]

Returns

- distances [ndarray of shape (n_samples,)]

Notes

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm.

sklearn.metrics.pairwise.paired_distances

`sklearn.metrics.pairwise.paired_distances(X, Y, *metric='euclidean', **kwds)`

Computes the paired distances between X and Y.

Computes the distances between (X[0], Y[0]), (X[1], Y[1]), etc…

Parameters

- X [ndarray of shape (n_samples, n_features)] Array 1 for distance computation.
- Y [ndarray of shape (n_samples, n_features)] Array 2 for distance computation.
- metric [str or callable, default="euclidean"] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options specified in PAIRED_DISTANCES, including “euclidean”, “manhattan”, or “cosine”. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting
value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

Returns

distances [ndarray of shape (n_samples,)]

See also:

pairwise_distances Computes the distance between every pair of samples.

Examples

```python
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([[0., 1.]])
```

sklearn.metrics.pairwise_distances

sklearn.metrics.pairwise_distances(X, Y=None, metric='euclidean', *, n_jobs=None, force_all_finite=True, **kwds)

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X and Y.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs. ['nan_euclidean'] but it does not yet support sparse matrices.
- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid scipy.spatial.distance metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the __doc__ of the sklearn.pairwise.distance_metrics function.

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_features)] Array of pairwise distances between samples, or a feature array. The shape of the array should be (n_samples_X, n_samples_X) if metric == “precomputed” and (n_samples_X, n_features) otherwise.
Y [ndarray of shape (n_samples_Y, n_features), default=None] An optional second feature array. Only allowed if metric != “precomputed”.

metric [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

force_all_finite [bool or 'allow-nan', default=True] Whether to raise an error on np.inf, np.nan, pd.NA in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accepts np.inf, np.nan, pd.NA in array.
- ‘allow-nan’: accepts only np.nan and pd.NA values in array. Values cannot be infinite.

New in version 0.22: force_all_finite accepts the string ‘allow-nan’.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan.

**kwds [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns

D [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_samples_Y)] A distance matrix D such that D_{i, j} is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_{i, j} is the distance between the ith array from X and the jth array from Y.

See also:

- pairwise_distances_chunked Performs the same calculation as this function, but returns a generator of chunks of the distance matrix, in order to limit memory usage.
- paired_distances Computes the distances between corresponding elements of two arrays.

Examples using sklearn.metrics.pairwise_distances

- Agglomerative clustering with different metrics
Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance).

This is mostly equivalent to calling:
```
pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)
```
but uses much less memory, and is faster for large arrays.

This function works with dense 2D arrays only.

**Parameters**

- **X** ([array-like of shape (n_samples_X, n_features)]) Array containing points.
- **Y** ([array-like of shape (n_samples_Y, n_features)]) Arrays containing points.
- **axis** ([int, default=1]) Axis along which the argmin and distances are to be computed.
- **metric** ([str or callable, default="euclidean"] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.
  
  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

  Distance matrices are not supported.

  Valid values for metric are:

  - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

  See the documentation for scipy.spatial.distance for details on these metrics.

- **metric_kwargs** ([dict, default=None]) Keyword arguments to pass to specified metric function.

**Returns**

- **argmin** ([numpy.ndarray]) Y[argmin[i], :] is the row in Y that is closest to X[i, :].

**See also:**

- `sklearn.metrics.pairwise_distances`
- `sklearn.metrics.pairwise_distances_argmin_min`
Examples using `sklearn.metrics.pairwise_distances_argmin`

- Color Quantization using K-Means
- Comparison of the K-Means and MiniBatchKMeans clustering algorithms

### `sklearn.metrics.pairwise_distances_argmin_min`

#### `sklearn.metrics.pairwise_distances_argmin_min(X, Y, *, axis=1, metric='euclidean', metric_kwargs=None)`

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance). The minimal distances are also returned.

This is mostly equivalent to calling:

```python
(pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis), pairwise_distances(X, Y=Y, metric=metric).min(axis=axis))
```

but uses much less memory, and is faster for large arrays.

**Parameters**

- **X** `[array-like, sparse matrix]` of shape (n_samples_X, n_features) Array containing points.
- **Y** `[array-like, sparse matrix]` of shape (n_samples_Y, n_features) Array containing points.
- **axis** `[int, default=1]` Axis along which the argmin and distances are to be computed.
- **metric** `[str or callable, default='euclidean']` Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

  Distance matrices are not supported.

- **metric_kwargs** `[dict, default=None]` Keyword arguments to pass to specified metric function.

**Returns**

- **argmin** `[ndarray]` Y[argmin[i, :]] is the row in Y that is closest to X[i, :].
- **distances** `[ndarray]` distances[i] is the distance between the i-th row in X and the argmin[i]-th row in Y.

**See also:**

- `sklearn.metrics.pairwise_distances`
- `sklearn.metrics.pairwise_distances_argmin`
sklearn.metrics.pairwise_distances_chunked

Generate a distance matrix chunk by chunk with optional reduction. In cases where not all of a pairwise distance matrix needs to be stored at once, this is used to calculate pairwise distances in working_memory-sized chunks. If reduce_func is given, it is run on each chunk and its return values are concatenated into lists, arrays or sparse matrices.

Parameters

- X [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_features)] Array of pairwise distances between samples, or a feature array. The shape the array should be (n_samples_X, n_samples_X) if metric='precomputed' and (n_samples_X, n_features) otherwise.

- Y [ndarray of shape (n_samples_Y, n_features), default=None] An optional second feature array. Only allowed if metric != "precomputed".

- reduce_func [callable, default=None] The function which is applied on each chunk of the distance matrix, reducing it to needed values. reduce_func(D_chunk, start) is called repeatedly, where D_chunk is a contiguous vertical slice of the pairwise distance matrix, starting at row start. It should return one of: None; an array, a list, or a sparse matrix of length D_chunk.shape[0]; or a tuple of such objects. Returning None is useful for in-place operations, rather than reductions.

- metric [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

- n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

- working_memory [int, default=None] The sought maximum memory for temporary distance matrix chunks. When None (default), the value of sklearn.get_config()['working_memory'] is used.

- **kwds [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Yields

- D_chunk [[ndarray, sparse matrix]] A contiguous slice of distance matrix, optionally processed by reduce_func.
Examples

Without reduce_func:

```python
>>> import numpy as np
gt> from sklearn.metrics import pairwise_distances_chunked
>>> X = np.random.RandomState(0).rand(5, 3)
>>> D_chunk = next(pairwise_distances_chunked(X))
>>> D_chunk
array([[0. ..., 0.29..., 0.41..., 0.19..., 0.57...],
       [0.29..., 0. ..., 0.57..., 0.41..., 0.76...],
       [0.41..., 0.57..., 0. ..., 0.44..., 0.90...],
       [0.19..., 0.41..., 0.44..., 0. ..., 0.51...],
       [0.57..., 0.76..., 0.90..., 0.51..., 0. ...]])
```

Retrieve all neighbors and average distance within radius r:

```python
>>> r = .2
>>> def reduce_func(D_chunk, start):
...     neigh = [np.flatnonzero(d < r) for d in D_chunk]
...     avg_dist = (D_chunk * (D_chunk < r)).mean(axis=1)
...     return neigh, avg_dist
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func)
>>> neigh, avg_dist = next(gen)
>>> neigh
[array([0, 3]), array([1]), array([2]), array([0, 3]), array([4])]
>>> avg_dist
array([0.039..., 0. , 0. , 0.039..., 0. ])
```

Where r is defined per sample, we need to make use of start:

```python
>>> r = [.2, .4, .4, .3, .1]
>>> def reduce_func(D_chunk, start):
...     neigh = [np.flatnonzero(d < r[i]) for i, d in enumerate(D_chunk, start)]
...     return neigh
>>> neigh = next(pairwise_distances_chunked(X, reduce_func=reduce_func))
>>> neigh
[array([0, 3]), array([0, 1]), array([2]), array([0, 3]), array([4])]
```

Force row-by-row generation by reducing working_memory:

```python
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func,
...                                   working_memory=0)
>>> next(gen)
[array([0, 3])]  # Warning: no guarantee on the order for multiple iterations
>>> next(gen)
[array([0, 1])]
```
## 7.24.8 Plotting

See the *Visualizations* section of the user guide for further details.

```python
metrics.plot_confusion_matrix(estimator, X, ..., )
```

Plot Confusion Matrix.

```python
metrics.plot_det_curve(estimator, X, y, *[...])
```

Plot detection error tradeoff (DET) curve.

```python
metrics.plot_precision_recall_curve(...[, ...
```

Plot Precision Recall Curve for binary classifiers.

```python
metrics.plot_roc_curve(estimator, X, y, *[...
```

Plot Receiver operating characteristic (ROC) curve.

### sklearn.metrics.plot_confusion_matrix

```python
sklearn.metrics.plot_confusion_matrix(estimator, X, y_true, *, labels=None, sample_weight=None, normalize=None, display_labels=None, include_values=True, xticks_rotation='horizontal', values_format=None, cmap='viridis', ax=None, colorbar=True)
```

Plot Confusion Matrix.

Read more in the *User Guide*.

**Parameters**

- `estimator` [estimator instance] Fitted classifier or a fitted `Pipeline` in which the last estimator is a classifier.

- `X` [array-like, sparse matrix] of shape (n_samples, n_features)] Input values.

- `y` [array-like of shape (n_samples,)] Target values.

- `labels` [array-like of shape (n_classes,), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If `None` is given, those that appear at least once in `y_true` or `y_pred` are used in sorted order.

- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

- `normalize` [{'true', 'pred', 'all'}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If `None`, confusion matrix will not be normalized.

- `display_labels` [array-like of shape (n_classes,), default=None] Target names used for plotting. By default, `labels` will be used if it is defined, otherwise the unique labels of `y_true` and `y_pred` will be used.

- `include_values` [bool, default=True] Includes values in confusion matrix.

- `xticks_rotation` [{‘vertical’, ‘horizontal’} or float, default=’horizontal’] Rotation of xtick labels.

- `values_format` [str, default=None] Format specification for values in confusion matrix. If `None`, the format specification is ‘d’ or ‘.2g’ whichever is shorter.

- `cmap` [str or matplotlib Colormap, default=’viridis’] Colormap recognized by matplotlib.

- `ax` [matplotlib Axes, default=None] Axes object to plot on. If `None`, a new figure and axes is created.
colorbar  [bool, default=True] Whether or not to add a colorbar to the plot.

    New in version 0.24.

Returns

display  [ConfusionMatrixDisplay]

See also:

confusion_matrix  Compute Confusion Matrix to evaluate the accuracy of a classification.

ConfusionMatrixDisplay  Confusion Matrix visualization.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import plot_confusion_matrix
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
>>> clf = SVC(random_state=0)
>>> clf.fit(X_train, y_train)
>>> clf
SVC(random_state=0)
>>> plot_confusion_matrix(clf, X_test, y_test)
>>> plt.show()
```

Examples using sklearn.metrics.plot_confusion_matrix

- Recognizing hand-written digits
- Confusion matrix

sklearn.metrics.plot_det_curve

sklearn.metrics.plot_det_curve(ester, X, y, *, sample_weight=None, response_method='auto', name=None, ax=None, pos_label=None, **kwargs)

Plot detection error tradeoff (DET) curve.

Extra keyword arguments will be passed to matplotlib’s plot.

Read more in the User Guide.

New in version 0.24.

Parameters

- estimator  [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator is a classifier.
- X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Input values.
- y  [array-like of shape (n_samples,)] Target values.
- sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.
response_method [{'predict_proba', 'decision_function', 'auto'} default='auto'] Specifies whether to use predict_proba or decision_function as the predicted target response. If set to 'auto', predict_proba is tried first and if it does not exist decision_function is tried next.

name [str, default=None] Name of DET curve for labeling. If None, use the name of the estimator.

ax [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

pos_label [str or int, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.

Returns
display [DetCurveDisplay] Object that stores computed values.

See also:
det_curve Compute error rates for different probability thresholds.
DetCurveDisplay DET curve visualization.
plot_roc_curve Plot Receiver operating characteristic (ROC) curve.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from sklearn import datasets, metrics, model_selection, svm
>>> X, y = datasets.make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = model_selection.train_test_split(...
...     X, y, random_state=0)
>>> clf = svm.SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> metrics.plot_det_curve(clf, X_test, y_test)
>>> plt.show()
```

Examples using sklearn.metrics.plot_det_curve

- Detection error tradeoff (DET) curve

sklearn.metrics.plot_precision_recall_curve

sklearn.metrics.plot_precision_recall_curve (estimator, X, y, *, sample_weight=None, response_method='auto', name=None, ax=None, pos_label=None, **kwargs)

Plot Precision Recall Curve for binary classifiers.

Extra keyword arguments will be passed to matplotlib's plot.

Read more in the User Guide.

Parameters

estimator [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator is a classifier.
X  [array-like, sparse matrix] of shape (n_samples, n_features) Input values.
y  [array-like of shape (n_samples,)] Binary target values.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.
response_method  [‘predict_proba’, ‘decision_function’, ‘auto’], default=’auto’] Specifies
whether to use predict_proba or decision_function as the target response. If set to ‘auto’,
predict_proba is tried first and if it does not exist decision_function is tried next.
name  [str, default=None] Name for labeling curve. If None, the name of the estimator is used.
ax  [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is
created.
pos_label  [str or int, default=None] The class considered as the positive class when computing
the precision and recall metrics. By default, estimators.classes_[1] is considered
as the positive class.
  New in version 0.24.
**kwargs  [dict] Keyword arguments to be passed to matplotlib’s plot.
Returns
display  [PrecisionRecallDisplay] Object that stores computed values.
See also:
precision_recall_curve  Compute precision-recall pairs for different probability thresholds.
PrecisionRecallDisplay  Precision Recall visualization.
Examples using sklearn.metrics.plot_precision_recall_curve

• Precision-Recall
sklearn.metrics.plot_roc_curve

sklearn.metrics.plot_roc_curve(estimator,  X,  y,  *,  sample_weight=None,
drop_intermediate=True, response_method=’auto’, name=None,
ax=None, pos_label=None, **kwargs)
Plot Receiver operating characteristic (ROC) curve.
Extra keyword arguments will be passed to matplotlib’s plot.
Read more in the User Guide.

Parameters
  estimator  [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator
  is a classifier.
  X  [array-like, sparse matrix] of shape (n_samples, n_features) Input values.
  y  [array-like of shape (n_samples,)] Target values.
  sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.
  drop_intermediate  [boolean, default=True] Whether to drop some suboptimal thresholds
  which would not appear on a plotted ROC curve. This is useful in order to create lighter
  ROC curves.
response_method (['predict_proba', 'decision_function', 'auto'] default='auto') Specifies whether to use predict_proba or decision_function as the target response. If set to 'auto', predict_proba is tried first and if it does not exist decision_function is tried next.

name [str, default=None] Name of ROC Curve for labeling. If None, use the name of the estimator.

ax [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

pos_label [str or int, default=None] The class considered as the positive class when computing the roc_auc metrics. By default, estimators.classes_[1] is considered as the positive class.

New in version 0.24.

Returns
display [RocCurveDisplay] Object that stores computed values.

See also:

roc_curve Compute Receiver operating characteristic (ROC) curve.

RocCurveDisplay ROC Curve visualization.

roc_auc_score Compute the area under the ROC curve.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from sklearn import datasets, metrics, model_selection, svm
>>> X, y = datasets.make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = model_selection.train_test_split(X, y, random_state=0)
>>> clf = svm.SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> metrics.plot_roc_curve(clf, X_test, y_test)
>>> plt.show()
```

sklearn.metrics.ConfusionMatrixDisplay

class sklearn.metrics.ConfusionMatrixDisplay(**kwargs)
Confusion Matrix visualization.

It is recommended to use plot_confusion_matrix to create a ConfusionMatrixDisplay. All parameters are stored as attributes.

Read more in the User Guide.

Parameters

confusion_matrix [ndarray of shape (n_classes, n_classes)] Confusion matrix.
display_labels [ndarray of shape (n_classes,), default=None] Display labels for plot. If None, display labels are set from 0 to n_classes - 1.

Attributes

im_ [matplotlib AxesImage] Image representing the confusion matrix.
text_ [ndarray of shape (n_classes, n_classes), dtype=matplotlib Text, or None] Array of matplotlib axes. None if include_values is false.
ax_ [matplotlib Axes] Axes with confusion matrix.
figure_ [matplotlib Figure] Figure containing the confusion matrix.

See also:

confusion_matrix Compute Confusion Matrix to evaluate the accuracy of a classification.
plot_confusion_matrix Plot Confusion Matrix.

Examples

```python
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import confusion_matrix, ConfusionMatrixDisplay
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, ...
... random_state=0)

>>>clf = SVC(random_state=0)

>>>clf.fit(X_train, y_train)
SVC(random_state=0)

>>>predictions = clf.predict(X_test)

>>> cm = confusion_matrix(y_test, predictions, labels=clf.classes_)

>>>disp = ConfusionMatrixDisplay(confusion_matrix=cm,
...     display_labels=clf.classes_)

>>> disp.plot()
```
Methods

```
plot(*[, include_values, cmap, ...])  Plot visualization.
```

```
plot(*, include_values=True, cmap='viridis', xticks_rotation='horizontal', values_format=None, ax=None, colorbar=True)
```

Plot visualization.

Parameters

- **include_values** [bool, default=True] Includes values in confusion matrix.
- **cmap** [str or matplotlib Colormap, default='viridis'] Colormap recognized by matplotlib.
- **xticks_rotation** [{'vertical', 'horizontal'} or float, default='horizontal'] Rotation of xtick labels.
- **values_format** [str, default=None] Format specification for values in confusion matrix. If None, the format specification is ‘d’ or ‘.2g’ whichever is shorter.
- **ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.
- **colorbar** [bool, default=True] Whether or not to add a colorbar to the plot.

Returns

- **display** [ConfusionMatrixDisplay]

Examples using sklearn.metrics.ConfusionMatrixDisplay

- Visualizations with Display Objects

sklearn.metrics.DetCurveDisplay

```
class sklearn.metrics.DetCurveDisplay (*, fpr, fnr, estimator_name=None, pos_label=None)  DET curve visualization.
```

It is recommend to use plot_det_curve to create a visualizer. All parameters are stored as attributes.

Read more in the User Guide.

New in version 0.24.

Parameters

- **fpr** [ndarray] False positive rate.
- **tpr** [ndarray] True positive rate.
- **estimator_name** [str, default=None] Name of estimator. If None, the estimator name is not shown.
- **pos_label** [str or int, default=None] The label of the positive class.

Attributes

- **line_** [matplotlib Artist] DET Curve.
- **ax_** [matplotlib Axes] Axes with DET Curve.
- **figure_** [matplotlib Figure] Figure containing the curve.
See also:

*det_curve* Compute error rates for different probability thresholds.

*plot_det_curve* Plot detection error tradeoff (DET) curve.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from sklearn import metrics

>>> y = np.array([0, 0, 1, 1])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, fnr, thresholds = metrics.det_curve(y, pred)
>>> display = metrics.DetCurveDisplay(fpr=fpr, fnr=fnr, estimator_name='example estimator')
>>> display.plot()
>>> plt.show()
```

Methods

```python
plot([ax, name]) Plot visualization.

plot (ax=None, *, name=None, **kwargs) Plot visualization.

Parameters

- ax [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.
- name [str, default=None] Name of DET curve for labeling. If None, use the name of the estimator.

Returns

- display [DetCurveDisplay] Object that stores computed values.
```

*sklearn.metrics.PrecisionRecallDisplay*

```python
class sklearn.metrics.PrecisionRecallDisplay(**kwargs) Precision Recall visualization.

It is recommend to use plot_precision_recall_curve to create a visualizer. All parameters are stored as attributes.

Read more in the User Guide.

Parameters

- precision [ndarray] Precision values.
- average_precision [float, default=None] Average precision. If None, the average precision is not shown.
```
**estimator_name** [str, default=None] Name of estimator. If None, then the estimator name is not shown.

**pos_label** [str or int, default=None] The class considered as the positive class. If None, the class will not be shown in the legend.

New in version 0.24.

**Attributes**

- **line_** [*matplotlib Artist*] Precision recall curve.
- **ax_** [*matplotlib Axes*] Axes with precision recall curve.
- **figure_** [*matplotlib Figure*] Figure containing the curve.

**See also:**

- `precision_recall_curve` Compute precision-recall pairs for different probability thresholds.
- `plot_precision_recall_curve` Plot Precision Recall Curve for binary classifiers.

**Examples**

```python
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import (precision_recall_curve, ...
... PrecisionRecallDisplay)
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, ...
... random_state=0)
>>> clf = SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> predictions = clf.predict(X_test)
>>> precision, recall, _ = precision_recall_curve(y_test, predictions)
>>> disp = PrecisionRecallDisplay(precision=precision, recall=recall)
>>> disp.plot()
```

**Methods**

- **plot([ax, name])**
  Plot visualization.

  Extra keyword arguments will be passed to matplotlib’s `plot`.

  **Parameters**

  - **ax** [Matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.
  
  - **name** [str, default=None] Name of precision recall curve for labeling. If None, use the name of the estimator.
  
  - ****kwargs [dict] Keyword arguments to be passed to matplotlib’s `plot`.
Returns

display [PrecisionRecallDisplay] Object that stores computed values.

Examples using sklearn.metrics.PrecisionRecallDisplay

- Visualizations with Display Objects

sklearn.metrics.RocCurveDisplay
class sklearn.metrics.RocCurveDisplay(**kwargs)
ROC Curve visualization.

It is recommend to use plot_roc_curve to create a visualizer. All parameters are stored as attributes.
Read more in the User Guide.

Parameters

- fpr [ndarray] False positive rate.
- tpr [ndarray] True positive rate.
- roc_auc [float, default=None] Area under ROC curve. If None, the roc_auc score is not shown.
- estimator_name [str, default=None] Name of estimator. If None, the estimator name is not shown.
- pos_label [str or int, default=None] The class considered as the positive class when computing the roc auc metrics. By default, estimators.classes_[1] is considered as the positive class.

New in version 0.24.

Attributes

- line_ [matplotlib Artist] ROC Curve.
- figure_ [matplotlib Figure] Figure containing the curve.

See also:

roc_curve Compute Receiver operating characteristic (ROC) curve.
plot_roc_curve Plot Receiver operating characteristic (ROC) curve.
roc_auc_score Compute the area under the ROC curve.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([0, 0, 1, 1])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred)
>>> roc_auc = metrics.auc(fpr, tpr)
>>> display = metrics.RocCurveDisplay(fpr=fpr, tpr=tpr, roc_auc=roc_auc, estimator_name='example estimator')
```

>>> display.plot()
>>> plt.show()

Methods

plot(ax=None, *, name=None, **kwargs)

Plot visualization

Extra keyword arguments will be passed to matplotlib’s plot.

Parameters

ax [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

name [str, default=None] Name of ROC Curve for labeling. If None, use the name of the estimator.

Returns

display [RocCurveDisplay] Object that stores computed values.

Examples using sklearn.metrics.RocCurveDisplay

• Visualizations with Display Objects

7.25 sklearn.mixture: Gaussian Mixture Models

The sklearn.mixture module implements mixture modeling algorithms.

User guide: See the Gaussian mixture models section for further details.

mixture.BayesianGaussianMixture(**kwargs) Variational Bayesian estimation of a Gaussian mixture.
mixture.GaussianMixture(**kwargs) Gaussian Mixture.

7.25.1 sklearn.mixture.BayesianGaussianMixture

class sklearn.mixture.BayesianGaussianMixture(**kwargs)

Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components (called the Stick-breaking representation). The number of components actually used almost always depends on the data.
New in version 0.18.

Read more in the User Guide.

Parameters

- **n_components** [int, default=1] The number of mixture components. Depending on the data and the value of the weight_concentration_prior the model can decide to not use all the components by setting some component weights to values very close to zero. The number of effective components is therefore smaller than n_components.

- **covariance_type** [str, default='full'] String describing the type of covariance parameters to use. Must be one of:

  - 'full' (each component has its own general covariance matrix),
  - 'tied' (all components share the same general covariance matrix),
  - 'diag' (each component has its own diagonal covariance matrix),
  - 'spherical' (each component has its own single variance).

- **tol** [float, default=1e-3] The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

- **reg_covar** [float, default=1e-6] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

- **max_iter** [int, default=100] The number of EM iterations to perform.

- **n_init** [int, default=1] The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

- **init_params** [str, default='kmeans'] The method used to initialize the weights, the means and the covariances. Must be one of:

  - 'kmeans' : responsibilities are initialized using kmeans.
  - 'random' : responsibilities are initialized randomly.

- **weight_concentration_prior_type** [str, default='dirichlet_process'] String describing the type of the weight concentration prior. Must be one of:

  - 'dirichlet_process' (using the Stick-breaking representation),
  - 'dirichlet_distribution' (can favor more uniform weights).

- **weight_concentration_prior** [float | None, default=None] The dirichlet concentration of each component on the weight distribution (Dirichlet). This is commonly called gamma in the literature. The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it’s set to 1. / n_components.

- **mean_precision_prior** [float | None, default=None] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around mean_prior. The value of the parameter must be greater than 0. If it is None, it is set to 1.

- **mean_prior** [array-like, shape (n_features,), default=None] The prior on the mean distribution (Gaussian). If it is None, it is set to the mean of X.

- **degrees_of_freedom_prior** [float | None, default=None] The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it’s set to n_features.
**covariance_prior**  [float or array-like, default=None.]  The prior on the covariance distribution (Wishart). If it is None, the empirical covariance prior is initialized using the covariance of X. The shape depends on `covariance_type`:

```
(n_features, n_features)  if 'full',
(n_features, n_features)  if 'tied',
(n_features)  if 'diag',
float  if 'spherical'
```

**random_state**  [int, RandomState instance or None, default=None]  Controls the random seed given to the method chosen to initialize the parameters (see `init_params`). In addition, it controls the generation of random samples from the fitted distribution (see the method `sample`). Pass an int for reproducible output across multiple function calls. See [Glossary](#).  

**warm_start**  [bool, default=False]  If `warm_start` is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several times on similar problems. See [Glossary](#).

**verbose**  [int, default=0]  Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

**verbose_interval**  [int, default=10]  Number of iteration done before the next print.

**Attributes**

**weights_**  [array-like of shape (n_components,)]  The weights of each mixture component.

**means_**  [array-like of shape (n_components, n_features)]  The mean of each mixture component.

**covariances_**  [array-like]  The covariance of each mixture component. The shape depends on `covariance_type`:

```
(n_components,)  if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features)  if 'diag',
(n_components, n_features, n_features)  if 'full'
```

**precisions_**  [array-like]  The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)  if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features)  if 'diag',
(n_components, n_features, n_features)  if 'full'
```

**precisions_chol**  [array-like]  The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:
converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of inference to reach the convergence.

lower_bound_ [float] Lower bound value on the likelihood (of the training data with respect to the model) of the best fit of inference.

weight_concentration_prior_ [tuple or float] The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on weight_concentration_prior_type:

(float, float) if 'dirichlet_process' (Beta parameters),
float           if 'dirichlet_distribution' (Dirichlet parameters).

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the simplex.

weight_concentration_ [array-like of shape (n_components,)] The dirichlet concentration of each component on the weight distribution (Dirichlet).

mean_precision_prior_ [float] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around mean_prior. If mean_precision_prior is set to None, mean_precision_prior_ is set to 1.

mean_precision_ [array-like of shape (n_components,)] The precision of each components on the mean distribution (Gaussian).

mean_prior_ [array-like of shape (n_features,)] The prior on the mean distribution (Gaussian).

degrees_of_freedom_prior_ [float] The prior of the number of degrees of freedom on the covariance distributions (Wishart).

degrees_of_freedom_ [array-like of shape (n_components,)] The number of degrees of freedom of each components in the model.

covariance_prior_ [float or array-like] The prior on the covariance distribution (Wishart). The shape depends on covariance_type:

(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features)          if 'diag',
float                if 'spherical'

**fit** *(X, y=None)*

Estimate model parameters with the EM algorithm.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. If `warm_start` is True, then `n_init` is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

**Parameters**

-X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

self

**fit_predict** *(X, y=None)*

Estimate model parameters using X and predict the labels for X.
The method fits the model n_init times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

Parameters

X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

labels [array, shape (n_samples,)] Component labels.

generate (deep=\text{True})

Get parameters for this estimator.

Parameters

depth [bool, default=\text{True}] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)

Predict the labels for the data samples in X using trained model.

Parameters

X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

labels [array, shape (n_samples,)] Component labels.

predict_proba (X)

Predict posterior probability of each component given the data.

Parameters

X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

resp [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

sample (n_samples=1)

Generate random samples from the fitted Gaussian distribution.

Parameters

n_samples [int, default=1] Number of samples to generate.

Returns

X [array, shape (n_samples, n_features)] Randomly generated sample

y [array, shape (nsamples,)] Component labels
score\((X, y=\text{None})\)
Compute the per-sample average log-likelihood of the given data \(X\).

Parameters

\(X\) [array-like of shape (\(n\_samples, n\_dimensions\))] List of \(n\_features\)-dimensional data points. Each row corresponds to a single data point.

Returns

log\_likelihood [float] Log likelihood of the Gaussian mixture given \(X\).

score\_samples\((X)\)
Compute the weighted log probabilities for each sample.

Parameters

\(X\) [array-like of shape (\(n\_samples, n\_features\))] List of \(n\_features\)-dimensional data points. Each row corresponds to a single data point.

Returns

log\_prob [array, shape (\(n\_samples,\))] Log probabilities of each data point in \(X\).

set\_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.mixture.BayesianGaussianMixture

- Gaussian Mixture Model Ellipsoids
- Gaussian Mixture Model Sine Curve
- Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture

7.25.2 sklearn.mixture.GaussianMixture

class sklearn.mixture.GaussianMixture (**kwargs)
Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

Read more in the User Guide.

New in version 0.18.

Parameters

n\_components [int, default=1] The number of mixture components.
covariance_type  [{‘full’, ‘tied’, ‘diag’, ‘spherical’}, default=‘full’] String describing the type of covariance parameters to use. Must be one of:
- ‘full’ each component has its own general covariance matrix
- ‘tied’ all components share the same general covariance matrix
- ‘diag’ each component has its own diagonal covariance matrix
- ‘spherical’ each component has its own single variance
tol  [float, default=1e-3] The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.
reg_covar  [float, default=1e-6] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.
max_iter  [int, default=100] The number of EM iterations to perform.
n_init  [int, default=1] The number of initializations to perform. The best results are kept.
init_params  [{‘kmeans’, ‘random’}, default=’kmeans’] The method used to initialize the weights, the means and the precisions. Must be one of:
- ‘kmeans’ : responsibilities are initialized using kmeans.
- ‘random’ : responsibilities are initialized randomly.
weights_init  [array-like of shape (n_components, ), default=None] The user-provided initial weights. If it is None, weights are initialized using the init_params method.
means_init  [array-like of shape (n_components, n_features), default=None] The user-provided initial means. If it is None, means are initialized using the init_params method.
precisions_init  [array-like, default=None] The user-provided initial precisions (inverse of the covariance matrices). If it is None, precisions are initialized using the ‘init_params’ method. The shape depends on ‘covariance_type’:

- (n_components,) if ‘spherical’,
- (n_features, n_features) if ‘tied’,
- (n_components, n_features) if ‘diag’,
- (n_components, n_features, n_features) if ‘full’
random_state  [int, RandomState instance or None, default=None] Controls the random seed given to the method chosen to initialize the parameters (see init_params). In addition, it controls the generation of random samples from the fitted distribution (see the method sample). Pass an int for reproducible output across multiple function calls. See Glossary.
warm_start  [bool, default=False] If ‘warm_start’ is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several times on similar problems. In that case, ‘n_init’ is ignored and only a single initialization occurs upon the first call. See the Glossary.
verbose  [int, default=0] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.
verbose_interval  [int, default=10] Number of iteration done before the next print.
Attributes
weights_  [array-like of shape (n_components,)] The weights of each mixture component.
means_ [array-like of shape (n_components, n_features)] The mean of each mixture component.

covariances_ [array-like] The covariance of each mixture component. The shape depends on covariance_type:

<table>
<thead>
<tr>
<th>Shape</th>
<th>covariance_type</th>

converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of EM to reach the convergence.

lower_bound_ [float] Lower bound value on the log-likelihood (of the training data with respect to the model) of the best fit of EM.

BayesianGaussianMixture Gaussian mixture model fit with a variational inference.

Examples

```python
>>> import numpy as np
>>> from sklearn.mixture import GaussianMixture
>>> X = np.array([[1, 2], 
                [1, 4], 
                [1, 0], 
                [10, 2], 
                [10, 4], 
                [10, 0]])
>>> gm = GaussianMixture(n_components=2, random_state=0).fit(X)
>>> gm.means_
array([[10., 2.],
        [1., 2.]])
>>> gm.predict([[0, 0], [12, 3]])
array([1, 0])
```

**aic(X)**

Akaike information criterion for the current model on the input X.

**Parameters**

- `X` [array of shape (n_samples, n_dimensions)]

**Returns**

- `aic` [float] The lower the better.

**bic(X)**

Bayesian information criterion for the current model on the input X.

**Parameters**

- `X` [array of shape (n_samples, n_dimensions)]

**Returns**

- `bic` [float] The lower the better.

**fit(X, y=None)**

Estimate model parameters with the EM algorithm.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. If `warm_start` is True, then `n_init` is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points.
  - Each row corresponds to a single data point.

**Returns**
**self**

**fit_predict** *(X, y=None)*

Estimate model parameters using X and predict the labels for X.

The method fits the model n_init times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a `ConvergenceWarning` is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **labels** [array, shape (n_samples,)] Component labels.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict the labels for the data samples in X using trained model.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **labels** [array, shape (n_samples,)] Component labels.

**predict_proba** *(X)*

Predict posterior probability of each component given the data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **resp** [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** *(n_samples=1)*

Generate random samples from the fitted Gaussian distribution.

**Parameters**

- **n_samples** [int, default=1] Number of samples to generate.

**Returns**
X [array, shape (n_samples, n_features)] Randomly generated sample
y [array, shape (nsamples,)] Component labels

score(X, y=None)
Compute the per-sample average log-likelihood of the given data X.

Parameters
- X [array-like of shape (n_samples, n_dimensions)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns
- log_likelihood [float] Log likelihood of the Gaussian mixture given X.

score_samples(X)
Compute the weighted log probabilities for each sample.

Parameters
- X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns
- log_prob [array, shape (n_samples,)] Log probabilities of each data point in X.

set_params(**params)
Set the parameters of this estimator.

Parameters
- **params [dict] Estimator parameters.

Returns

**sklearn.model_selection.GroupKFold**

```python
class sklearn.model_selection.GroupKFold(n_splits=5)
```

K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same in each fold.

Read more in the *User Guide*.

**Parameters**

- `n_splits` [int, default=5] Number of folds. Must be at least 2.

  Changed in version 0.22: `n_splits` default value changed from 3 to 5.

**See also:**

- `LeaveOneGroupOut` For splitting the data according to explicit domain-specific stratification of the dataset.
Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]]
```

Methods

- `get_n_splits([X, y, groups])` Returns the number of splitting iterations in the cross-validator
- `split(X, y=None, groups=None)` Generate indices to split data into training and test set.

**get_n_splits** *(X=None, y=None, groups=None)*

Returns the number of splitting iterations in the cross-validator

**Parameters**

- X [object] Always ignored, exists for compatibility.
- y [object] Always ignored, exists for compatibility.
- groups [object] Always ignored, exists for compatibility.

**Returns**

- n_splits [int] Returns the number of splitting iterations in the cross-validator.

**split** *(X=None, y=None, groups=None)*

Generate indices to split data into training and test set.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.

groups [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Examples using sklearn.model_selection.GroupKFold

- Visualizing cross-validation behavior in scikit-learn

sklearn.model_selection.GroupShuffleSplit
class sklearn.model_selection.GroupShuffleSplit(**kwargs)

Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and GroupShuffleSplit is that the former generates splits using all subsets of size $p$ unique groups, whereas GroupShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to LeavePGroupsOut($p=10$) would be GroupShuffleSplit(test_size=10, n_splits=100).

Note: The parameters test_size and train_size refer to groups, and not to samples, as in ShuffleSplit. Read more in the User Guide.

Parameters

- n_splits [int, default=5] Number of re-shuffling & splitting iterations.
- test_size [float, int, default=0.2] If float, should be between 0.0 and 1.0 and represent the proportion of groups to include in the test split (rounded up). If int, represents the absolute number of test groups. If None, the value is set to the complement of the train size. The default will change in version 0.21. It will remain 0.2 only if train_size is unspecified, otherwise it will complement the specified train_size.
- train_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.
- random_state [int, RandomState instance or None, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See Glossary.
Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import GroupShuffleSplit

>>> X = np.ones(shape=(8, 2))
>>> y = np.ones(shape=(8, 1))
>>> groups = np.array([1, 1, 2, 2, 2, 3, 3, 3])
>>> print(groups.shape)
(8,)
>>> gss = GroupShuffleSplit(n_splits=2, train_size=.7, random_state=42)
>>> gss.get_n_splits()
2
>>> for train_idx, test_idx in gss.split(X, y, groups):
...     print("TRAIN:", train_idx, "TEST:", test_idx)
TRAIN: [2 3 4 5 6 7] TEST: [0 1]
TRAIN: [0 1 5 6 7] TEST: [2 3 4]
```

Methods

<table>
<thead>
<tr>
<th>get_n_splits([X, y, groups])</th>
<th>Returns the number of splitting iterations in the cross-validator</th>

</tr>
</tbody>
</table>

**get_n_splits** (*X=None, y=None, groups=None*)

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X, y=None, groups=None*)

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.
Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

Examples using `sklearn.model_selection.GroupShuffleSplit`

- Visualizing cross-validation behavior in scikit-learn

`sklearn.model_selection.KFold`

class `sklearn.model_selection.KFold(**kwargs)`

K-Folds cross-validator

Provides train/test indices to split data in train/test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the k - 1 remaining folds form the training set.

Read more in the User Guide.

Parameters

- `n_splits` [int, default=5] Number of folds. Must be at least 2.
  
  Changed in version 0.22: `n_splits` default value changed from 3 to 5.

- `shuffle` [bool, default=False] Whether to shuffle the data before splitting into batches. Note that the samples within each split will not be shuffled.

- `random_state` [int, RandomState instance or None, default=None] When `shuffle` is True, `random_state` affects the ordering of the indices, which controls the randomness of each fold. Otherwise, this parameter has no effect. Pass an int for reproducible output across multiple function calls. See Glossary.

See also:

- `StratifiedKFold` Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).

- `GroupKFold` K-fold iterator variant with non-overlapping groups.

- `RepeatedKFold` Repeats K-Fold n times.

Notes

The first `n_samples % n_splits` folds have size `n_samples // n_splits + 1`, other folds have size `n_samples // n_splits`, where `n_samples` is the number of samples.

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.
Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]
```

**get_n_splits** *(X=None, y=None, groups=None)*

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** *(X, y=None, groups=None)*

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

`sklearn.model_selection.LeaveOneGroupOut`

```python
class sklearn.model_selection.LeaveOneGroupOut

Leave One Group Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the User Guide.
```

Examples

```python
>>> import numpy as np
def from sklearn.model_selection import LeaveOneGroupOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
>>> logo = LeaveOneGroupOut()
>>> logo.get_n_splits(X, y, groups)
2
>>> logo.get_n_splits(groups=groups)  # 'groups' is always required
2
>>> logo = LeaveOneGroupOut()
>>> for train_index, test_index in logo.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     print("X_train, X_test = X[train_index], X[test_index]"
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print("y_train, y_test = y[train_index], y[test_index]"
...     y_train, y_test = y[train_index], y[test_index]
...     print("TRAIN: [", train_index, "] TEST: [", test_index, "]")
...     TRAIN: [2 3] TEST: [0 1]
[[5 6] [7 8]] [1 2]
[[3 4]] [1 2] [1 2]
... TRAIN: [0 1] TEST: [2 3]
[[1 2] [3 4]] [1 2] [1 2]
[[5 6] [7 8]] [1 2] [1 2]
```

</tbody>
</table>

### `get_n_splits`(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator.

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

### `split`(X, y=None, groups=None)

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

### `sklearn.model_selection.LeavePGroupsOut`

**class sklearn.model_selection.LeavePGroupsOut(n_groups)**

Leave P Group(s) Out cross-validator.

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with all the samples assigned to p different values of the groups while the latter uses samples all assigned the same groups.

Read more in the *User Guide*.

**Parameters**
n_groups  [int] Number of groups (p) to leave out in the test split.

See also:

GroupKFold  K-fold iterator variant with non-overlapping groups.

Examples

```python
code_snippet
>>> import numpy as np
>>> from sklearn.model_selection import LeavePGroupsOut
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups)  # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]
[3 4]] [1 1]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]
[5 6]] [2] [1 1]
TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]
[5 6]] [1] [2 1]
```

Methods

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>get_n_splits(X, y, groups)</td>
<td>Returns the number of splitting iterations in the cross-validator.</td>
</tr>
<tr>
<td>split(X, y, groups)</td>
<td>Generate indices to split data into training and test set.</td>
</tr>
</tbody>
</table>

get_n_splits (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.
n_splits [int] Returns the number of splitting iterations in the cross-validator.

split(X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

- X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- y [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.
- groups [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

Yields

- train [ndarray] The training set indices for that split.
- test [ndarray] The testing set indices for that split.

sklearn.model_selection.LeaveOneOut

class sklearn.model_selection.LeaveOneOut
Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: LeaveOneOut() is equivalent to KFold(n_splits=n) and LeavePOut(p=1) where n is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor KFold, ShuffleSplit or StratifiedKFold.

Read more in the User Guide.

See also:

- LeaveOneGroupOut For splitting the data according to explicit, domain-specific stratification of the dataset.
- GroupKFold K-fold iterator variant with non-overlapping groups.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneOut
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = LeaveOneOut()
>>> loo.get_n_splits(X)
2
>>> print(loo)
LeaveOneOut()
>>> for train_index, test_index in loo.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
```

(continues on next page)
Methods

**get_n_splits**(*X*, *y*[, *groups]*)  
Returns the number of splitting iterations in the cross-validator

**split**(*X*, *y*[, *groups]*)  
Generate indices to split data into training and test set.

---

### get_n_splits

get_n_splits(*X*, *y*[, *groups*])

Returns the number of splitting iterations in the cross-validator.

#### Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

#### Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

### split

split(*X*, *y*[, *groups*])

Generate indices to split data into training and test set.

#### Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

#### Yields

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

---

**sklearn.model_selection.LeavePOut**

class sklearn.model_selection.LeavePOut(*p*)

Leave-P-Out cross-validator

Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

#### Note

LeavesPOut(*p*) is NOT equivalent to KFold(n_splits=n_samples // p) which creates non-overlapping test sets.
Due to the high number of iterations which grows combinatorically with the number of samples this cross-validation method can be very costly. For large datasets one should favor \texttt{KFold}, \texttt{StratifiedKFold} or \texttt{ShuffleSplit}.

Read more in the \textit{User Guide}.

**Parameters**

- \texttt{p} [int] Size of the test sets. Must be strictly less than the number of samples.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeavePOut

>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = LeavePOut(2)
>>> lpo.get_n_splits(X)
6
>>> print(lpo)
LeavePOut(p=2)

>>> for train_index, test_index in lpo.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]
```

**Methods**

- \texttt{get_n_splits(X, y, groups)}
  Returns the number of splitting iterations in the cross-validator

- \texttt{split(X, y, groups)}
  Generate indices to split data into training and test set.

\texttt{get_n_splits} (\texttt{X}, \texttt{y=None, groups=None})
Returns the number of splitting iterations in the cross-validator

**Parameters**

- \texttt{X} [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

- \texttt{y} [object] Always ignored, exists for compatibility.

- \texttt{groups} [object] Always ignored, exists for compatibility.

\texttt{split} (\texttt{X}, \texttt{y=None, groups=None})
Generate indices to split data into training and test set.

**Parameters**
X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

ey [array-like of shape (n_samples,)] The target variable for supervised learning problems.
groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

sklearn.model_selection.PredefinedSplit

class sklearn.model_selection.PredefinedSplit(test_fold)
Predefined split cross-validator
Provides train/test indices to split data into train/test sets using a predefined scheme specified by the user with the test_fold parameter.
Read more in the User Guide.
New in version 0.16.

Parameters

test_fold [array-like of shape (n_samples,)] The entry test_fold[i] represents the index of the test set that sample i belongs to. It is possible to exclude sample i from any test set (i.e. include sample i in every training set) by setting test_fold[i] equal to -1.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> ps.get_n_splits()
2
>>> print(ps)
PredefinedSplit(test_fold=array([0, 1, -1, 1]))
>>> for train_index, test_index in ps.split():
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [0 2 3] TEST: [1]
TRAIN: [0 2] TEST: [1 3]
```

#### get_n_splits

**get_n_splits** *(X=None, y=None, groups=None)*

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

#### split

**split** *(X=None, y=None, groups=None)*

Generate indices to split data into training and test set.

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

---

**sklearn.model_selection.RepeatedKFold**

**class sklearn.model_selection.RepeatedKFold(**kwargs)**

Repeated K-Fold cross validator.

Repeats K-Fold n times with different randomization in each repetition.

**Parameters**

- **n_splits** [int, default=5] Number of folds. Must be at least 2.
- **n_repeats** [int, default=10] Number of times cross-validator needs to be repeated.
- **random_state** [int, RandomState instance or None, default=None] Controls the randomness of each repeated cross-validation instance. Pass an int for reproducible output across multiple function calls. See [Glossary](https://scikit-learn.org/stable/glossary.html).

**See also:**

- **RepeatedStratifiedKFold** Repeats Stratified K-Fold n times.
Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     TRAIN: [0 1] TEST: [2 3]
     TRAIN: [2 3] TEST: [0 1]
     TRAIN: [1 2] TEST: [0 3]
     TRAIN: [0 3] TEST: [1 2]
```

Methods

```python
get_n_splits([X, y, groups])

Returns the number of splitting iterations in the cross-validator
```

```python
split(X, y=None, groups=None)

Generates indices to split data into training and test set.
```

get_n_splits (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

X [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

y [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)

Generates indices to split data into training and test set.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] The target variable for supervised learning problems.
groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Examples using sklearn.model_selection.RepeatedKFold

- Common pitfalls in interpretation of coefficients of linear models

sklearn.model_selection.RepeatedStratifiedKFold
class sklearn.model_selection.RepeatedStratifiedKFold(**kwargs)
Repeated Stratified K-Fold cross validator.
Repeats Stratified K-Fold n times with different randomization in each repetition.
Read more in the User Guide.

Parameters

n_splits [int, default=5] Number of folds. Must be at least 2.
n_repeats [int, default=10] Number of times cross-validator needs to be repeated.
random_state [int, RandomState instance or None, default=None] Controls the generation of the random states for each repetition. Pass an int for reproducible output across multiple function calls. See Glossary.

See also:

RepeatedKFold Repeats K-Fold n times.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2,
... random_state=36851234)
>>> for train_index, test_index in rskf.split(X, y):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print("X_train, X_test = ", X_train, X_test)
...     print("y_train, y_test = ", y_train, y_test)
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
```

#### `get_n_splits (X=None, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

**Parameters**

- `X` [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- `y` [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- `groups` [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

- `n_splits` [int] Returns the number of splitting iterations in the cross-validator.

#### `split (X, y=None, groups=None)`

Generates indices to split data into training and test set.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like of shape (n_samples,)] The target variable for supervised learning problems.
- `groups` [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- `train` [ndarray] The training set indices for that split.
- `test` [ndarray] The testing set indices for that split.

#### `sklearn.model_selection.ShuffleSplit`

**class sklearn.model_selection.ShuffleSplit (**kwargs)**

Random permutation cross-validator

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the User Guide.
Parameters

- **n_splits** [int, default=10] Number of re-shuffling & splitting iterations.
- **test_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If **train_size** is also None, it will be set to 0.1.
- **train_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.
- **random_state** [int, RandomState instance or None, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See Glossary.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=5, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
5
>>> print(rs)
ShuffleSplit(n_splits=5, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0 4] TEST: [5 2]
TRAIN: [4 0 2 5] TEST: [1 3]
TRAIN: [1 2 4 0] TEST: [3 5]
TRAIN: [3 4 1 0] TEST: [5 2]
TRAIN: [3 5 1 0] TEST: [2 4]
>>> rs = ShuffleSplit(n_splits=5, train_size=0.5, test_size=.25, random_state=0)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0] TEST: [5 2]
TRAIN: [4 0 2] TEST: [1 3]
TRAIN: [1 2 4] TEST: [3 5]
TRAIN: [3 4 1] TEST: [5 2]
TRAIN: [3 5 1] TEST: [2 4]
```

Methods

- **get_n_splits**([X, y, groups]) Returns the number of splitting iterations in the cross-validator.
- **split**([X, y, groups]) Generate indices to split data into training and test set.

```
get_n_splits(X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator
```

7.26. sklearn.model_selection: Model Selection 2441
Parameters

X [object] Always ignored, exists for compatibility.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like of shape (n_samples,)] The target variable for supervised learning problems.
groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.ShuffleSplit

- Visualizing cross-validation behavior in scikit-learn
- Plotting Learning Curves
- Scaling the regularization parameter for SVCs

sklearn.model_selection.StratifiedKFold

class sklearn.model_selection.StratifiedKFold(**kwargs)

Stratified K-Folds cross-validator.

Provides train/test indices to split data in train/test sets.

This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the User Guide.

Parameters

n_splits [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: n_splits default value changed from 3 to 5.
**shuffle** [bool, default=False] Whether to shuffle each class’s samples before splitting into batches. Note that the samples within each split will not be shuffled.

**random_state** [int, RandomState instance or None, default=None] When **shuffle** is True, **random_state** affects the ordering of the indices, which controls the randomness of each fold for each class. Otherwise, leave **random_state** as None. Pass an int for reproducible output across multiple function calls. See *Glossary*.

See also:

*RepeatedStratifiedKFold* Repeats Stratified K-Fold n times.

**Notes**

The implementation is designed to:

- Generate test sets such that all contain the same distribution of classes, or as close as possible.
- Be invariant to class label: relabelling \(y = \text{["Happy", "Sad"]}\) to \(y = [1, 0]\) should not change the indices generated.
- Preserve order dependencies in the dataset ordering, when **shuffle=False**: all samples from class \(k\) in some test set were contiguous in \(y\), or separated in \(y\) by samples from classes other than \(k\).
- Generate test sets where the smallest and largest differ by at most one sample.

Changed in version 0.22: The previous implementation did not follow the last constraint.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

**Methods**

- **get_n_splits**([X, y, groups]) Returns the number of splitting iterations in the cross-validator
- **split**(X, y[, groups]) Generate indices to split data into training and test set.

**get_n_splits** (X=None, y=None, groups=None) Returns the number of splitting iterations in the cross-validator

7.26. sklearn.model_selection: Model Selection 2443
Parameters

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split**(X, y, groups=None)

Generate indices to split data into training and test set.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
  
  Note that providing y is sufficient to generate the splits and hence np.zeros(n_samples) may be used as a placeholder for X instead of actual training data.
- **y** [array-like of shape (n_samples,)] The target variable for supervised learning problems. Stratification is done based on the y labels.
- **groups** [object] Always ignored, exists for compatibility.

Yields

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.StratifiedKFold

- Recursive feature elimination with cross-validation
- Test with permutations the significance of a classification score
- GMM covariances
- Receiver Operating Characteristic (ROC) with cross validation
- Visualizing cross-validation behavior in scikit-learn
sklearn.model_selection.StratifiedShuffleSplit

class sklearn.model_selection.StratifiedShuffleSplit(**kwargs)

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the User Guide.

Parameters

n_splits [int, default=10] Number of re-shuffling & splitting iterations.

test_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If train_size is also None, it will be set to 0.1.

train_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See Glossary.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 0, 1, 1, 1])
>>> sss = StratifiedShuffleSplit(n_splits=5, test_size=0.5, random_state=0)
>>> sss.get_n_splits(X, y)
5
>>> print(sss)
StratifiedShuffleSplit(n_splits=5, random_state=0, ...)
>>> for train_index, test_index in sss.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [5 2 3] TEST: [4 1 0]
TRAIN: [5 1 4] TEST: [0 2 3]
TRAIN: [5 0 2] TEST: [4 3 1]
TRAIN: [4 1 0] TEST: [2 3 5]
TRAIN: [0 5 1] TEST: [3 4 2]
```

get_n_splits (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

- X [object] Always ignored, exists for compatibility.
- y [object] Always ignored, exists for compatibility.
- groups [object] Always ignored, exists for compatibility.

Returns

- n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y, groups=None)

Generate indices to split data into training and test set.

Parameters

- X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
  
  Note that providing y is sufficient to generate the splits and hence np.zeros(n_samples) may be used as a placeholder for X instead of actual training data.
- y [array-like of shape (n_samples,) or (n_samples, n_labels)] The target variable for supervised learning problems. Stratification is done based on the y labels.
- groups [object] Always ignored, exists for compatibility.

Yields

- train [ndarray] The training set indices for that split.
- test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.StratifiedShuffleSplit

- Visualizing cross-validation behavior in scikit-learn
- RBF SVM parameters
**sklearn.model_selection.TimeSeriesSplit**

class `sklearn.model_selection.TimeSeriesSplit(**kwargs)`

Time Series cross-validator

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of `KFold`. In the kth split, it returns first k folds as train set and the (k+1)th fold as test set.

Note that unlike standard cross-validation methods, successive training sets are supersets of those that come before them.

Read more in the *User Guide*.

New in version 0.18.

**Parameters**

- `n_splits` [int, default=5] Number of splits. Must be at least 2.

  Changed in version 0.22: `n_splits` default value changed from 3 to 5.

- `max_train_size` [int, default=None] Maximum size for a single training set.

- `test_size` [int, default=None] Used to limit the size of the test set. Defaults to `n_samples // (n_splits + 1)`, which is the maximum allowed value with `gap=0`.

  New in version 0.24.

- `gap` [int, default=0] Number of samples to exclude from the end of each train set before the test set.

  New in version 0.24.

**Notes**

The training set has size
\[ \frac{i \times n \_ samples}{n \_ splits + 1} + n \_ samples \mod (n \_ splits + 1) \]

in the \(i\)’th split, with a test set of size \(\frac{n \_ samples}{n \_ splits + 1}\) by default, where `n_samples` is the number of samples.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import TimeSeriesSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> tscv = TimeSeriesSplit()
>>> print(tscv)
TimeSeriesSplit(gap=0, max_train_size=None, n_splits=5, test_size=None)
>>> for train_index, test_index in tscv.split(X):
...     print("TRAIN": train_index, "TEST": test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
TRAIN: [0 1] TEST: [2]
TRAIN: [0 1 2] TEST: [3]
TRAIN: [0 1 2 3] TEST: [4]
```

(continues on next page)
TRAIN: [0 1 2 3 4] TEST: [5]

Fix test_size to 2 with 12 samples

X = np.random.randn(12, 2)
y = np.random.randint(0, 2, 12)
tscv = TimeSeriesSplit(n_splits=3, test_size=2)

for train_index, test_index in tscv.split(X):
    print("TRAIN:", train_index, "TEST:", test_index)
    X_train, X_test = X[train_index], X[test_index]
    y_train, y_test = y[train_index], y[test_index]

TRAIN: [0 1 2 3 4 5] TEST: [6 7]
TRAIN: [0 1 2 3 4 5 6 7] TEST: [8 9]
TRAIN: [0 1 2 3 4 5 6 7 8 9] TEST: [10 11]

Add in a 2 period gap

tscv = TimeSeriesSplit(n_splits=3, test_size=2, gap=2)

for train_index, test_index in tscv.split(X):
    print("TRAIN:", train_index, "TEST:", test_index)
    X_train, X_test = X[train_index], X[test_index]
    y_train, y_test = y[train_index], y[test_index]

TRAIN: [0 1 2 3] TEST: [6 7]
TRAIN: [0 1 2 3 4 5] TEST: [8 9]
TRAIN: [0 1 2 3 4 5 6 7] TEST: [10 11]

Methods

:get_n_splits:(X, y, groups)

Returns the number of splitting iterations in the cross-validator

:split:(X, y, groups)

Generate indices to split data into training and test set.

:get_n_splits:(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

-X [object] Always ignored, exists for compatibility.
-y [object] Always ignored, exists for compatibility.
-groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

:split:(X, y=None, groups=None)

Generate indices to split data into training and test set.

Parameters

-X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
-y [array-like of shape (n_samples,)] Always ignored, exists for compatibility.
-groups [array-like of shape (n_samples,)] Always ignored, exists for compatibility.

Yields

train [ndarray] The training set indices for that split.

### 7.26.2 Splitter Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>model_selection.check_cv</code></td>
<td>Input checker utility for building a cross-validator</td>
</tr>
<tr>
<td><code>model_selection.train_test_split</code></td>
<td>Split arrays or matrices into random train and test subsets</td>
</tr>
</tbody>
</table>

#### sklearn.model_selection.check_cv

**sklearn.model_selection.check_cv**(cv=5, y=None, *, classifier=False)

Input checker utility for building a cross-validator

**Parameters**

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are: - None, to use the default 5-fold cross-validation, - integer, to specify the number of folds, - CV splitter, - An iterable yielding (train, test) splits as arrays of indices.

  For integer/None inputs, if classifier is True and y is either binary or multiclass, **StratifiedKFold** is used. In all other cases, **KFold** is used.

  Refer User Guide for the various cross-validation strategies that can be used here.

  Changed in version 0.22: cv default value changed from 3-fold to 5-fold.

- **y** [array-like, default=None] The target variable for supervised learning problems.

- **classifier** [bool, default=False] Whether the task is a classification task, in which case stratified KFold will be used.

**Returns**

- **checked_cv** [a cross-validator instance.] The return value is a cross-validator which generates the train/test splits via the split method.

#### sklearn.model_selection.train_test_split

**sklearn.model_selection.train_test_split**(arrays..., test_size=None, train_size=None, random_state=None, shuffle=True, stratify=None)

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and next(ShuffleSplit().split(X, y)) and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the User Guide.

**Parameters**

- **arrays** [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.
**test_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If **train_size** is also None, it will be set to 0.25.

**train_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

**random_state** [int, RandomState instance or None, default=None] Controls the shuffling applied to the data before applying the split. Pass an int for reproducible output across multiple function calls. See **Glossary**.

**shuffle** [bool, default=True] Whether or not to shuffle the data before splitting. If shuffle=False then stratify must be None.

**stratify** [array-like, default=None] If not None, data is split in a stratified fashion, using this as the class labels.

**Returns**

**splitting** [list, length=2 * len(arrays)] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a **scipy.sparse.csr_matrix**. Else, output type is the same as the input type.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]

>>> X_train, X_test, y_train, y_test = train_test_split(...
X, y, test_size=0.33, random_state=42)
...
>>> X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]

>>> train_test_split(y, shuffle=False)
[[0, 1, 2], [3, 4]]

</tr>
</tbody>
</table>

```python
sklearn.model_selection.GridSearchCV

class sklearn.model_selection.GridSearchCV(**kwargs)
Exhaustive search over specified parameter values for an estimator.

Important members are fit, predict.

GridSearchCV implements a “fit” and a “score” method. It also implements “score_samples”, “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the User Guide.

Parameters

estimator [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.
```
**param_grid** [dict or list of dictionaries] Dictionary with parameters names (str) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

**scoring** [str, callable, list/tuple or dict, default=None] A single str (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See *Specifying multiple metrics for evaluation* for an example.

If None, the estimator’s score method is used.

**n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a *joblib.parallel_backend* context. -1 means using all processors. See *Glossary* for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

**pre_dispatch** [int, or str, default=n_jobs] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)*KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**refit** [bool, str, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a str denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, refit can be set to a function which returns the selected best_index_ given cv_results_. In that case, the best_estimator_ and best_params_ will be set
according to the returned `best_index_` while the `best_score_` attribute will not be available.

The refitted estimator is made available at the `best_estimator_` attribute and permits using `predict` directly on this `GridSearchCV` instance.

Also for multiple metric evaluation, the attributes `best_index_`, `best_score_` and `best_params_` will only be available if `refit` is set and all of them will be determined \( w.r.t \) this specific scorer.

See `scoring` parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**`verbose`** [int] Controls the verbosity: the higher, the more messages.

- \( >1 \): the computation time for each fold and parameter candidate is displayed;
- \( >2 \): the score is also displayed;
- \( >3 \): the fold and candidate parameter indexes are also displayed together with the starting time of the computation.

**`error_score`** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

**`return_train_score`** [bool, default=False] If False, the `cv_results_` attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from True to False

**Attributes**

**`cv_results_`** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>param_degree</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_t...</th>
</tr>
</thead>
<tbody>
<tr>
<td>'poly'</td>
<td></td>
<td>2</td>
<td>0.80</td>
<td>...</td>
<td>2</td>
</tr>
<tr>
<td>'poly'</td>
<td></td>
<td>3</td>
<td>0.70</td>
<td>...</td>
<td>4</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td></td>
<td>0.80</td>
<td>...</td>
<td>3</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td></td>
<td>0.93</td>
<td>...</td>
<td>1</td>
</tr>
</tbody>
</table>

will be represented by a `cv_results_` dict of:

```python
{
    'param_kernel': masked_array(data = ['poly', 'poly', 'rbf', 'rbf'],
                               mask = [False False False False]...)
    'param_gamma': masked_array(data = [-- -- 0.1 0.2],
                        mask = [ True  True False False]...),
    'param_degree': masked_array(data = [2.0 3.0 -- --],
                     mask = [False False True True]...),
    'split0_test_score' : [0.80, 0.70, 0.80, 0.93],
}
```

(continues on next page)
NOTE

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The mean_fit_time, std_fit_time, mean_score_time and std_score_time are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the cv_results_ dict at the keys ending with that scorer's name ('_<scorer_name>'), instead of '_score' shown above. ('split0_test_precision', 'mean_train_precision' etc.)

best_estimator_ [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

See refit parameter for more information on allowed values.

best_score_ [float] Mean cross-validated score of the best_estimator

For multi-metric evaluation, this is present only if refit is specified.

This attribute is not available if refit is a function.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is present only if refit is specified.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is present only if refit is specified.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated scoring dict which maps the scorer key to the scorer callable.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

refit_time_ [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.
New in version 0.20.

**multimetric_** [bool] Whether or not the scorers compute several metrics.

See also:

*ParameterGrid* Generates all the combinations of a hyperparameter grid.

*train_test_split* Utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.

*sklearn.metrics.make_scorer* Make a scorer from a performance metric or loss function.

**Notes**

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If `n_jobs` was set to a value higher than one, the data is copied for each point in the grid (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

**Examples**

```python
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV

iris = datasets.load_iris()
parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
svc = svm.SVC()
clf = GridSearchCV(svc, parameters)
clf.fit(iris.data, iris.target)
>>> sorted(clf.cv_results_.keys())
['mean_fit_time', 'mean_score_time', 'mean_test_score', ...
 'param_C', 'param_kernel', 'params', ...
 'rank_test_score', 'split0_test_score', ...
 'split2_test_score', ...
 'std_fit_time', 'std_score_time', 'std_test_score']
```

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

<tr>
<td><code>inverse_transform(Xt)</code></td>
<td>Call inverse_transform on the estimator with the best found params.</td>
</tr>
<tr>
<td><code>predict(X)</code></td>
<td>Call predict on the estimator with the best found parameters.</td>
</tr>
</tbody>
</table>
predict_log_proba \( (X) \)  
Call predict_log_proba on the estimator with the best found parameters.

predict_proba \( (X) \)  
Call predict_proba on the estimator with the best found parameters.

score \( (X, y) \)  
Returns the score on the given data, if the estimator has been refit.

score_samples \( (X) \)  
Call score_samples on the estimator with the best found parameters.

set_params \( (**params) \)  
Set the parameters of this estimator.

transform \( (X) \)  
Call transform on the estimator with the best found parameters.

decision_function \( (X) \)  
Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

Parameters

\( X \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

fit \( (X, y=None, *, groups=None, **fit_params) \)  
Run fit with all sets of parameters.

Parameters

\( X \) [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

\( y \) [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

\( groups \) [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_params [dict of str -> object] Parameters passed to the fit method of the estimator

get_params \( (deep=True) \)  
Get parameters for this estimator.

Parameters

\( deep \) [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform \( (X_t) \)  
Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.

Parameters

\( X_t \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
predict \((X)\)
Call predict on the estimator with the best found parameters.
Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports predict.

Parameters
- \(X\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_log_proba \((X)\)
Call predict_log_proba on the estimator with the best found parameters.
Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports predict_log_proba.

Parameters
- \(X\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_proba \((X)\)
Call predict_proba on the estimator with the best found parameters.
Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports predict_proba.

Parameters
- \(X\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

score \((X, y=None)\)
Returns the score on the given data, if the estimator has been refit.
This uses the score defined by \text{scoring} where provided, and the best_estimator_.score method otherwise.

Parameters
- \(X\) [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.
- \(y\) [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to \(X\) for classification or regression; None for unsupervised learning.

Returns
- score [float]

score_samples \((X)\)
Call score_samples on the estimator with the best found parameters.
Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports score_samples.
New in version 0.24.

Parameters
- \(X\) [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns
- y_score [ndarray of shape (n_samples,)]

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.GridSearchCV

- Sample pipeline for text feature extraction and evaluation

sklearn.model_selection.HalvingGridSearchCV

```python
class sklearn.model_selection.HalvingGridSearchCV(estimator, param_grid, *, factor=3, resource='n_samples', max_resource='auto', min_resource='exhaust', aggressive_elimination=False, cv=5, scoring=None, refit=True, error_score=nan, return_train_score=True, random_state=None, n_jobs=None, verbose=0)
```

Search over specified parameter values with successive halving.

The search strategy starts evaluating all the candidates with a small amount of resources and iteratively selects the best candidates, using more and more resources.

Read more in the User guide.

Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_halving_search_cv:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_halving_search_cv
>>> from sklearn.model_selection import HalvingGridSearchCV
```

Parameters

**estimator** [estimator object.] This is assumed to implement the scikit-learn estimator interface.

Either estimator needs to provide a score function, or scoring must be passed.
**param_grid** [dict or list of dictionaries] Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

**factor** [int or float, default=3] The ‘halving’ parameter, which determines the proportion of candidates that are selected for each subsequent iteration. For example, factor=3 means that only one third of the candidates are selected.

**resource** ['n_samples' or str, default='n_samples'] Defines the resource that increases with each iteration. By default, the resource is the number of samples. It can also be set to any parameter of the base estimator that accepts positive integer values, e.g. ‘n_iterations’ or ‘n_estimators’ for a gradient boosting estimator. In this case max_resources cannot be ‘auto’ and must be set explicitly.

**max_resources** [int, default='auto'] The maximum amount of resource that any candidate is allowed to use for a given iteration. By default, this is set to n_samples when resource='n_samples' (default), else an error is raised.

**min_resources** ['exhaust', 'smallest'] or int, default='exhaust'] The minimum amount of resource that any candidate is allowed to use for a given iteration. Equivalently, this defines the amount of resources r0 that are allocated for each candidate at the first iteration.

- ‘smallest’ is a heuristic that sets r0 to a small value:
  - n_splits * 2 when resource='n_samples' for a regression problem
  - n_classes * n_splits * 2 when resource='n_samples' for a classification problem
  - 1 when resource != 'n_samples'

- ‘exhaust’ will set r0 such that the last iteration uses as much resources as possible. Namely, the last iteration will use the highest value smaller than max_resources that is a multiple of both min_resources and factor. In general, using ‘exhaust’ leads to a more accurate estimator, but is slightly more time consuming.

Note that the amount of resources used at each iteration is always a multiple of min_resources.

**aggressive_elimination** [bool, default=False] This is only relevant in cases where there isn’t enough resources to reduce the remaining candidates to at most factor after the last iteration. If True, then the search process will ‘replay’ the first iteration for as long as needed until the number of candidates is small enough. This is False by default, which means that the last iteration may evaluate more than factor candidates. See Aggressive elimination of candidates for more details.

**cv** [int, cross-validation generator or iterable, default=5] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.
Note: Due to implementation details, the folds produced by cv must be the same across multiple calls to cv.split(). For built-in scikit-learn iterators, this can be achieved by deactivating shuffling (shuffle=False), or by setting the cv’s random_state parameter to an integer.

scoring [string, callable, or None, default=None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set. If None, the estimator’s score method is used.

refit [bool, default=True] If True, refit an estimator using the best found parameters on the whole dataset.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this GridSearchCV instance.

error_score ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is np.nan

return_train_score [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

random_state [int, RandomState instance or None, default=None] Pseudo random number generator state used for subsampling the dataset when resources != 'n_samples'. Ignored otherwise. Pass an int for reproducible output across multiple function calls. See Glossary.

n_jobs [int or None, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int] Controls the verbosity: the higher, the more messages.

Attributes

n_resources_ [list of int] The amount of resources used at each iteration.

n_candidates_ [list of int] The number of candidate parameters that were evaluated at each iteration.

n_remaining_candidates_ [int] The number of candidate parameters that are left after the last iteration. It corresponds to ceil(n_candidates[-1] / factor)

max_resources_ [int] The maximum number of resources that any candidate is allowed to use for a given iteration. Note that since the number of resources used at each iteration must be a multiple of min_resources_, the actual number of resources used at the last iteration may be smaller than max_resources_.

min_resources_ [int] The amount of resources that are allocated for each candidate at the first iteration.

n_iterations_ [int] The actual number of iterations that were run. This is equal to n_required_iterations_ if aggressive_elimination is True. Else, this is equal to min(n_possible_iterations_, n_required_iterations_).
n_possible_iterations_ [int] The number of iterations that are possible starting with min_resources_ and without exceeding max_resources_.

n_required_iterations_ [int] The number of iterations that are required to end up with less than factor candidates at the last iteration, starting with min_resources_. This will be smaller than n_possible_iterations_ when there isn’t enough resources.

cv_results_ [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame. It contains many informations for analysing the results of a search. Please refer to the User guide for details.

best_estimator_ [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ [float] Mean cross-validated score of the best_estimator.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

refit_time_ [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.

See also:

HalvingRandomSearchCV Random search over a set of parameters using successive halving.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.experimental import enable_halving_search_cv  # noqa
>>> from sklearn.model_selection import HalvingGridSearchCV
...
>>> X, y = load_iris(return_X_y=True)
>>> clf = RandomForestClassifier(random_state=0)
...
>>> param_grid = {
...    "max_depth": [3, None],
...    "min_samples_split": [5, 10]
... }
>>> search = HalvingGridSearchCV(clf, param_grid, resource='n_estimators',
... max_resources=10,
... refit=True
... )
```

### decision_function(X)

Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

**Parameters**

- X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit** (X, y=None, groups=None, **fit_params)

Run fit with all sets of parameters.

**Parameters**

- X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- y [array-like, shape (n_samples,) or (n_samples, n_output), optional] Target relative to X for classification or regression; None for unsupervised learning.
- groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).
- **fit_params** [dict of string -> object] Parameters passed to the fit method of the estimator.
**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**inverse_transform** *(Xt)*

Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

**Parameters**

- **Xt** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict** *(X)*

Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports predict.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba** *(X)*

Call predict_log_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports predict_log_proba.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_proba** *(X)*

Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports predict_proba.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score** *(X, y=None)*

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

**Returns**
score [float]

score_samples(X)
Call score_samples on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports score_samples.
New in version 0.24.

Parameters
X [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns
y_score [ndarray of shape (n_samples,)]

set_params(**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform(X)
Call transform on the estimator with the best found parameters.
Only available if the underlying estimator supports transform and refit=True.

Parameters
X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.HalvingGridSearchCV

- Successive Halving Iterations
- Comparison between grid search and successive halving

sklearn.model_selection.ParameterGrid
class sklearn.model_selection.ParameterGrid(param_grid)
Grid of parameters with a discrete number of values for each.
Can be used to iterate over parameter value combinations with the Python built-in function iter. The order of the generated parameter combinations is deterministic.
Read more in the User Guide.

Parameters
param_grid [dict of str to sequence, or sequence of such] The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.
An empty dict signifies default parameters.
A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

See also:

**GridSearchCV** Uses *ParameterGrid* to perform a full parallelized parameter search.

### Examples

```python
>>> from sklearn.model_selection import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == 
[{'a': 1, 'b': True}, {'a': 1, 'b': False},
 {'a': 2, 'b': True}, {'a': 2, 'b': False}]
True
```

```python
>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{'kernel': 'linear'},
... {'kernel': 'rbf', 'gamma': 1},
... {'kernel': 'rbf', 'gamma': 10}]
True
```

```python
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
```

### sklearn.model_selection.ParameterSampler

**class sklearn.model_selection.ParameterSampler(**kwargs)**

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper-parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the *User Guide*.

**Parameters**

- **param_distributions** [dict] Dictionary with parameters names *(str)* as keys and distributions or lists of parameters to try. Distributions must provide a *rvs* method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

- **n_iter** [int] Number of parameter settings that are produced.

- **random_state** [int, RandomState instance or None, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- **params** [dict of str to any] *Yields* dictionaries mapping each estimator parameter to as sampled value.
Examples

```python
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np

>>> rng = np.random.RandomState(0)

>>> param_grid = {'a': [1, 2], 'b': expon()}

>>> param_list = list(ParameterSampler(param_grid, n_iter=4, random_state=rng))

>>> rounded_list = [{k: round(v, 6) for k, v in d.items()} for d in param_list]

>>> rounded_list == [{'b': 0.89856, 'a': 1},
...                   {'b': 0.923223, 'a': 1},
...                   {'b': 1.878964, 'a': 2},
...                   {'b': 1.038159, 'a': 2}]
True
```

**sklearn.model_selection.RandomizedSearchCV**

class sklearn.model_selection.RandomizedSearchCV(**kwargs)

Randomized search on hyper parameters.

RandomizedSearchCV implements a “fit” and a “score” method. It also implements “score_samples”, “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by `n_iter`.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the *User Guide*.

New in version 0.14.

**Parameters**

- **estimator** [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

- **param_distributions** [dict or list of dicts] Dictionary with parameters names (str) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

- **n_iter** [int, default=10] Number of parameter settings that are sampled. `n_iter` trades off runtime vs quality of the solution.

- **scoring** [str, callable, list/tuple or dict, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.
For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See `Specifying multiple metrics for evaluation` for an example.

If None, the estimator’s score method is used.

**n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

**pre_dispatch** [int, or str, default=None] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- `CV splitter`,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer `User Guide` for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**refit** [bool, str, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a str denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, **refit** can be set to a function which returns the selected best_index_ given the cv_results. In that case, the best_estimator_ and best_params_ will be set according to the returned best_index_ while the best_score_ attribute will not be available.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this RandomizedSearchCV instance.

Also for multiple metric evaluation, the attributes best_index_, best_score_ and best_params_ will only be available if refit is set and all of them will be determined w.r.t this specific scorer.
See `scoring` parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**verbose** [int] Controls the verbosity: the higher, the more messages.

**random_state** [int, RandomState instance or None, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. Pass an int for reproducible output across multiple function calls. See Glossary.

**error_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

**return_train_score** [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from True to False

**Attributes**

**cv_results_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_test_score</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td>0.80</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>0.84</td>
<td></td>
<td>3</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.3</td>
<td>0.70</td>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

will be represented by a cv_results_dict of:

```python
{
    'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'],
                                  mask = False),
    'param_gamma' : masked_array(data = [0.1 0.2 0.3], mask = False),
    'split0_test_score' : [0.80, 0.84, 0.70],
    'split1_test_score' : [0.82, 0.50, 0.70],
    'mean_test_score' : [0.81, 0.67, 0.70],
    'std_test_score' : [0.01, 0.24, 0.00],
    'rank_test_score' : [1, 3, 2],
    'split0_train_score' : [0.80, 0.92, 0.70],
    'split1_train_score' : [0.82, 0.55, 0.70],
    'mean_train_score' : [0.81, 0.74, 0.70],
    'std_train_score' : [0.01, 0.19, 0.00],
    'mean_fit_time' : [0.73, 0.63, 0.43],
    'std_fit_time' : [0.01, 0.02, 0.01],
    'mean_score_time' : [0.01, 0.06, 0.04],
    'std_score_time' : [0.00, 0.00, 0.00],
    'params' : [{"kernel" : 'rbf', 'gamma' : 0.1}, ...],
}
NOTE

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the `cv_results_` dict at the keys ending with that scorer’s name (`_<scorer_name>`) instead of '_score' shown above. ('split0_test_precision', 'mean_train_precision' etc.)

best_estimator_ [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

For multi-metric evaluation, this attribute is present only if refit is specified.

See refit parameter for more information on allowed values.

best_score_ [float] Mean cross-validated score of the best_estimator.

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

This attribute is not available if refit is a function.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated scoring dict which maps the scorer key to the scorer callable.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

refit_time_ [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.

New in version 0.20.

multimetric_ [bool] Whether or not the scorers compute several metrics.

See also:

GridSearchCV Does exhaustive search over a grid of parameters.

ParameterSampler A generator over parameter settings, constructed from param_distributions.
Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If n_jobs was set to a value higher than one, the data is copied for each parameter setting (and not n_jobs times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set pre_dispatch. Then, the memory is copied only pre_dispatch many times. A reasonable value for pre_dispatch is 2 * n_jobs.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.model_selection import RandomizedSearchCV
>>> from scipy.stats import uniform

>>> iris = load_iris()
>>> logistic = LogisticRegression(solver='saga', tol=1e-2, max_iter=200,
...                               random_state=0)
>>> distributions = dict(C=uniform(loc=0, scale=4),
...                       penalty=['l2', 'l1'])
>>> clf = RandomizedSearchCV(logistic, distributions, random_state=0)
>>> search = clf.fit(iris.data, iris.target)
>>> search.best_params_
{'C': 2..., 'penalty': 'l1'}
```

Methods

- `decision_function(X)` - Call decision_function on the estimator with the best found parameters.
- `fit(X[, y, groups])` - Run fit with all sets of parameters.
- `get_params([deep])` - Get parameters for this estimator.
- `inverse_transform(Xt)` - Call inverse_transform on the estimator with the best found params.
- `predict(X)` - Call predict on the estimator with the best found parameters.
- `predict_log_proba(X)` - Call predict_log_proba on the estimator with the best found parameters.
- `predict_proba(X)` - Call predict_proba on the estimator with the best found parameters.
- `score(X[, y])` - Returns the score on the given data, if the estimator has been refit.
- `score_samples(X)` - Call score_samples on the estimator with the best found parameters.
- `set_params(**params)` - Set the parameters of this estimator.
- `transform(X)` - Call transform on the estimator with the best found parameters.

- `decision_function(X)`
  Call decision_function on the estimator with the best found parameters.
Only available if \texttt{refit=True} and the underlying estimator supports \texttt{decision_function}.

**Parameters**

\( \text{X} \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit** (\( X, y=None, *, groups=None, **fit_params \))

Run fit with all sets of parameters.

**Parameters**

\( \text{X} \) [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

\( y \) [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to \( X \) for classification or regression; None for unsupervised learning.

\( \text{groups} \) [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” \texttt{cv} instance (e.g., \texttt{GroupKFold}).

**\texttt{**fit_params}** [dict of str -> object] Parameters passed to the \texttt{fit} method of the estimator

**get_params** (\texttt{deep=True})

Get parameters for this estimator.

**Parameters**

\texttt{deep} [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

\texttt{params} [dict] Parameter names mapped to their values.

**inverse_transform** (\( \text{Xt} \))

Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements \texttt{inverse_transform} and \texttt{refit=True}.

**Parameters**

\( \text{Xt} \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict** (\( \text{X} \))

Call predict on the estimator with the best found parameters.

Only available if \texttt{refit=True} and the underlying estimator supports \texttt{predict}.

**Parameters**

\( \text{X} \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba** (\( \text{X} \))

Call predict_log_proba on the estimator with the best found parameters.

Only available if \texttt{refit=True} and the underlying estimator supports \texttt{predict_log_proba}.

**Parameters**

\( \text{X} \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
predict_proba \((X)\)

Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

Parameters

\(X \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

score \((X, y=None)\)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

Parameters

\(X \) [array-like of shape \((n_samples, n_features)\)] Input data, where \(n_samples\) is the number of samples and \(n_features\) is the number of features.

\(y \) [array-like of shape \((n_samples, n_output)\) or \((n_samples,)\), default=None] Target relative to \(X\) for classification or regression; None for unsupervised learning.

Returns

score [float]

score_samples \((X)\)

Call score_samples on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `score_samples`.

New in version 0.24.

Parameters

\(X \) [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns

\(y_{score} \) [ndarray of shape \((n_samples,)\)]

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform \((X)\)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

Parameters

\(X \) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
Examples using `sklearn.model_selection.RandomizedSearchCV`

- Comparing randomized search and grid search for hyperparameter estimation

`sklearn.model_selection.HalvingRandomSearchCV`

```python
class sklearn.model_selection.HalvingRandomSearchCV(estimator,  
 param_distributions,  
 *, n_candidates='exhaust', factor=3,  
 resource='n_samples',  
 max_resources='auto',  
 min_resources='smallest',  
 aggressive_elimination=False,  
 cv=5, scoring=None, refit=True,  
 error_score=nan, return_train_score=True, random_state=None, n_jobs=None, verbose=0)
```

Randomized search on hyper parameters.

The search strategy starts evaluating all the candidates with a small amount of resources and iteratively selects the best candidates, using more and more resources.

The candidates are sampled at random from the parameter space and the number of sampled candidates is determined by `n_candidates`.

Read more in the User guide.

**Note:** This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_halving_search_cv`:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_halving_search_cv
>>> # noqa

>>> from sklearn.model_selection import HalvingRandomSearchCV
```

**Parameters**

- **estimator** [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

- **param_distributions** [dict] Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a rvs method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly.

- **n_candidates** [int, default='exhaust'] The number of candidate parameters to sample, at the first iteration. Using ‘exhaust’ will sample enough candidates so that the last iteration uses as many resources as possible, based on `min_resources`, `max_resources` and `factor`. In this case, `min_resources` cannot be ‘exhaust’.

- **factor** [int or float, default=3] The ‘halving’ parameter, which determines the proportion of candidates that are selected for each subsequent iteration. For example, `factor=3` means that only one third of the candidates are selected.

- **resource** ['n_samples' or str, default='n_samples'] Defines the resource that increases with each iteration. By default, the resource is the number of samples. It can also be set to any parameter of the base estimator that accepts positive integer values, e.g. ‘n_iterations’ or
scikit-learn user guide, Release 0.24.dev0

'n_estimators' for a gradient boosting estimator. In this case max_resources cannot be 'auto' and must be set explicitly.

**max_resources** [int, default='auto'] The maximum number of resources that any candidate is allowed to use for a given iteration. By default, this is set n_samples when resource='n_samples' (default), else an error is raised.

**min_resources** [{'exhaust', 'smallest'} or int, default='smallest'] The minimum amount of resource that any candidate is allowed to use for a given iteration. Equivalently, this defines the amount of resources r0 that are allocated for each candidate at the first iteration.

- 'smallest' is a heuristic that sets r0 to a small value:
  - n_splits * 2 when resource='n_samples' for a regression problem
  - n_classes * n_splits * 2 when resource='n_samples' for a classification problem
  - 1 when resource != 'n_samples'

- 'exhaust' will set r0 such that the last iteration uses as much resources as possible. Namely, the last iteration will use the highest value smaller than max_resources that is a multiple of both min_resources and factor. In general, using 'exhaust' leads to a more accurate estimator, but is slightly more time consuming. 'exhaust' isn’t available when n_candidates='exhaust'.

Note that the amount of resources used at each iteration is always a multiple of min_resources.

**aggressive_elimination** [bool, default=False] This is only relevant in cases where there isn’t enough resources to reduce the remaining candidates to at most factor after the last iteration. If True, then the search process will ‘replay’ the first iteration for as long as needed until the number of candidates is small enough. This is False by default, which means that the last iteration may evaluate more than factor candidates. See Aggressive elimination of candidates for more details.

**cv** [int, cross-validation generator or an iterable, default=5] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

**Note:** Due to implementation details, the folds produced by cv must be the same across multiple calls to cv.split(). For built-in scikit-learn iterators, this can be achieved by deactivating shuffling (shuffle=False), or by setting the cv’s random_state parameter to an integer.

**scoring** [string, callable, or None, default=None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set. If None, the estimator’s score method is used.
**refit** [bool, default=True] If True, refit an estimator using the best found parameters on the whole dataset.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this GridSearchCV instance.

**error_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is np.nan

**return_train_score** [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

**random_state** [int, RandomState instance or None, default=None] Pseudo random number generator state used for subsampling the dataset when resources != 'n_samples'. Also used for random uniform sampling from lists of possible values instead of scipy.stats distributions. Pass an int for reproducible output across multiple function calls. See Glossary.

**n_jobs** [int or None, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**verbose** [int] Controls the verbosity: the higher, the more messages.

**Attributes**

**n_resources_** [list of int] The amount of resources used at each iteration.

**n_candidates_** [list of int] The number of candidate parameters that were evaluated at each iteration.

**n_remainingCandidates_** [int] The number of candidate parameters that are left after the last iteration. It corresponds to ceil(n_candidates[-1] / factor)

**max_resources_** [int] The maximum number of resources that any candidate is allowed to use for a given iteration. Note that since the number of resources used at each iteration must be a multiple of min_resources_, the actual number of resources used at the last iteration may be smaller than max_resources_.

**min_resources_** [int] The amount of resources that are allocated for each candidate at the first iteration.

**n_iterations_** [int] The actual number of iterations that were run. This is equal to n_required_iterations_ if aggressive_elimination is True. Else, this is equal to min(n_possible_iterations_, n_required_iterations_).

**n_possible_iterations_** [int] The number of iterations that are possible starting with min_resources_ resources and without exceeding max_resources_.

**n_required_iterations_** [int] The number of iterations that are required to end up with less than factor candidates at the last iteration, starting with min_resources_ resources. This will be smaller than n_possible_iterations_ when there isn’t enough resources.

**cv_results_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame. It contains many informations for analysing the results of a search. Please refer to the User guide for details.
**best_estimator_** [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

**best_score_** [float] Mean cross-validated score of the best_estimator.

**best_params_** [dict] Parameter setting that gave the best results on the hold out data.

**best_index_** [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

   The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

**scorer_** [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

**n_splits_** [int] The number of cross-validation splits (folds/iterations).

**refit_time_** [float] Seconds used for refitting the best model on the whole dataset.

   This is present only if refit is not False.

See also:

*HalvingGridSearchCV*  Search over a grid of parameters using successive halving.

**Notes**

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

**Examples**

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.experimental import enable_halving_search_cv  # noqa
>>> from sklearn.model_selection import HalvingRandomSearchCV
>>> from scipy.stats import randint
... >>> X, y = load_iris(return_X_y=True)
>>> clf = RandomForestClassifier(random_state=0)
>>> np.random.seed(0)
... >>> param_distributions = {
...     'max_depth': [3, None],
...     'min_samples_split': randint(2, 11)
... }
>>> search = HalvingRandomSearchCV(clf, param_distributions,
...     resource='n_estimators',
...     max_resources=10,
...     random_state=0).fit(X, y)
>>> search.best_params_
{'max_depth': None, 'min_samples_split': 10, 'n_estimators': 9}
```
## Methods

### `decision_function(X)`
Call decision_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

**Parameters**

`X` [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

### `fit(X, y=None, groups=None, **fit_params)`
Run fit with all sets of parameters.

**Parameters**

`X` [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

`y` [array-like, shape (n_samples,) or (n_samples, n_output), optional] Target relative to X for classification or regression; None for unsupervised learning.

`groups` [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” `cv` instance (e.g., `GroupKFold`).

**fit_params** [dict of string -> object] Parameters passed to the `fit` method of the estimator

### `get_params([deep])`
Get parameters for this estimator.

**Parameters**

`deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
params [dict] Parameter names mapped to their values.

inverse_transform(Xt)
Call inverse_transform on the estimator with the best found params.
Only available if the underlying estimator implements inverse_transform and refit=True.

Parameters
Xt [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict(X)
Call predict on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports predict.

Parameters
X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_log_proba(X)
Call predict_log_proba on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports predict_log_proba.

Parameters
X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_proba(X)
Call predict_proba on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports predict_proba.

Parameters
X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

score(X, y=None)
Returns the score on the given data, if the estimator has been refit.
This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.

Parameters
X [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.
y [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

Returns
score [float]

score_samples(X)
Call score_samples on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports score_samples.
New in version 0.24.
Parameters

X [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns

y_score [ndarray of shape (n_samples,)]

set_params (**params)
Set the parameters of this estimator.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.HalvingRandomSearchCV

- Successive Halving Iterations

7.26.4 Model validation

<table>

<tr>
<td>model_selection.validation_curve(estimator, ...)</td>
<td>Validation curve.</td>
</tr>
</tbody>
</table>
Evaluate metric(s) by cross-validation and also record fit/score times.

Read more in the User Guide.

Parameters

- **estimator** [estimator object implementing `fit`] The object to use to fit the data.
- **X** [array-like of shape (n_samples, n_features)] The data to fit. Can be for example a list, or an array.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).
- **scoring** [str, callable, list/tuple, or dict, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s score method is used.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (Stratified)KFold,
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **n_jobs** [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the cross-validation splits. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

- **verbose** [int, default=0] The verbosity level.
**fit_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

**pre_dispatch** [int or str, default='2*n_jobs'] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**return_train_score** [bool, default=False] Whether to include train scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from True to False

**return_estimator** [bool, default=False] Whether to return the estimators fitted on each split.

New in version 0.20.

**error_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.

**Returns**

**scores** [dict of float arrays of shape (n_splits,)] Array of scores of the estimator for each run of the cross validation.

A dict of arrays containing the score/time arrays for each scorer is returned. The possible keys for this dict are:

- **test_score** The score array for test scores on each cv split. Suffix _score in test_score changes to a specific metric like test_r2 or test_auc if there are multiple scoring metrics in the scoring parameter.

- **train_score** The score array for train scores on each cv split. Suffix _score in train_score changes to a specific metric like train_r2 or train_auc if there are multiple scoring metrics in the scoring parameter. This is available only if return_train_score parameter is True.

- **fit_time** The time for fitting the estimator on the train set for each cv split.

- **score_time** The time for scoring the estimator on the test set for each cv split. (Note time for scoring on the train set is not included even if return_train_score is set to True.

- **estimator** The estimator objects for each cv split. This is available only if return_estimator parameter is set to True.

**See also:**

*cross_val_score* Run cross-validation for single metric evaluation.
**cross_val_predict**  Get predictions from each split of cross-validation for diagnostic purposes.

**sklearn.metrics.make_scorer**  Make a scorer from a performance metric or loss function.

### Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_validate
>>> from sklearn.metrics import make_scorer
>>> from sklearn.svm import LinearSVC

>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()

Single metric evaluation using `cross_validate`

```python
>>> cv_results = cross_validate(lasso, X, y, cv=3)
>>> sorted(cv_results.keys())
['fit_time', 'score_time', 'test_score']

>>> cv_results['test_score']
array([0.33150734, 0.08022311, 0.03531764])
```

Multiple metric evaluation using `cross_validate` (please refer the `scoring` parameter doc for more information)

```python
>>> scores = cross_validate(lasso, X, y, cv=3,
...     scoring=('r2', 'neg_mean_squared_error'),
...     return_train_score=True)

>>> print(scores['test_neg_mean_squared_error'])
[-3635.5... -3573.3... -6114.7...]

>>> print(scores['train_r2'])
[0.28010158 0.39088426 0.22784852]
```
Read more in the *User Guide*.

**Parameters**

- **estimator** [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.
- **X** [array-like of shape (n_samples, n_features)] The data to fit. Can be, for example a list, or an array at least 2d.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” `cv` instance (e.g., `GroupKFold`).
- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (Stratified)KFold,
  - *CV splitter*,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

- **n_jobs** [int, default=None] Number of jobs to run in parallel. Training the estimator and predicting are parallelized over the cross-validation splits. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

- **verbose** [int, default=0] The verbosity level.

- **fit_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

- **pre_dispatch** [int or str, default=’2*n_jobs’] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
  - None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
  - An int, giving the exact number of total jobs that are spawned
  - A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**Returns**

- **predictions** [ndarray] This is the result of calling `method`. Shape:
  - When `method` is ‘predict’ and in special case where `method` is ‘decision_function’ and the target is binary: (n_samples,)
• When `method` is one of {'predict_proba', 'predict_log_proba', 'decision_function'}
  (unless special case above): (n_samples, n_classes)
• If `estimator` is `multiclass`, an extra dimension `n_outputs` is added to the end of each
  shape above.

See also:

`cross_val_score` Calculate score for each CV split.
`cross_validate` Calculate one or more scores and timings for each CV split.

Notes

In the case that one or more classes are absent in a training portion, a default score needs to be assigned to
all instances for that class if `method` produces columns per class, as in {'decision_function', 'predict_proba',
'predict_log_proba'}. For `predict_proba` this value is 0. In order to ensure finite output, we approximate
negative infinity by the minimum finite float value for the dtype in other cases.

Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y, cv=3)
```

Examples using `sklearn.model_selection.cross_val_predict`

• Combine predictors using stacking
• Plotting Cross-Validated Predictions

`sklearn.model_selection.cross_val_score`

Evaluate a score by cross-validation

Read more in the User Guide.

Parameters

- `estimator` [estimator object implementing ‘fit’] The object to use to fit the data.
- `X` [array-like of shape (n_samples, n_features)] The data to fit. Can be for example a list, or an
  array.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] The target vari-
  able to try to predict in the case of supervised learning.
groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

scoring [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y) which should return only a single value.

Similar to cross_validate but only a single metric is permitted.

If None, the estimator’s default scorer (if available) is used.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross validation,
• int, to specify the number of folds in a (Stratified)KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

n_jobs [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the cross-validation splits. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int, default=0] The verbosity level.

fit_params [dict, default=None] Parameters to pass to the fit method of the estimator.

pre_dispatch [int or str, default=‘2*n_jobs’] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
• An int, giving the exact number of total jobs that are spawned
• A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

error_score ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.

Returns

scores [ndarray of float of shape=(len(list(cv)),)] Array of scores of the estimator for each run of the cross validation.

See also:
**cross_val_score** To run cross-validation on multiple metrics and also to return train scores, fit times and score times.

**cross_val_predict** Get predictions from each split of cross-validation for diagnostic purposes.

**sklearn.metrics.make_scorer** Make a scorer from a performance metric or loss function.

**Examples**

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y, cv=3))
[0.33150734 0.08022311 0.03531764]
```

**Examples using sklearn.model_selection.cross_val_score**

- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
- Underfitting vs. Overfitting
- Receiver Operating Characteristic (ROC) with cross validation
- Nested versus non-nested cross-validation
- SVM-Anova: SVM with univariate feature selection
- Cross-validation on Digits Dataset Exercise

**sklearn.model_selection.learning_curve**

```python
sklearn.model_selection.learning_curve(estimator, X, y, *, groups=None,
train_sizes=array([0.1, 0.33, 0.55, 0.78, 1.0]), cv=None, scoring=None,
exploit_incremental_learning=False, n_jobs=None,
pre_dispatch='all', verbose=0, shuffle=False,
random_state=None, error_score=nan, return_times=False,
fit_params=None)
```

**Learning curve.**

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the *User Guide*.

**Parameters**

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.
X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target relative to X for classification or regression; None for unsupervised learning.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

train_sizes [array-like of shape (n_ticks,), default=np.linspace(0.1, 1.0, 5)] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  • None, to use the default 5-fold cross validation,
  • int, to specify the number of folds in a (Stratified)KFold,
  • CV splitter,
  • An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

scoring [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

exploit_incremental_learning [bool, default=False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

n_jobs [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the different training and test sets. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

pre_dispatch [int or str, default='all'] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The str can be an expression like '2*n_jobs'.

verbose [int, default=0] Controls the verbosity: the higher, the more messages.

shuffle [bool, default=False] Whether to shuffle training data before taking prefixes of it based on "train_sizes".

random_state [int, RandomState instance or None, default=None] Used when shuffle is True. Pass an int for reproducible output across multiple function calls. See Glossary.

error_score ['raise’ or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.
**return_times** [bool, default=False] Whether to return the fit and score times.

**fit_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

New in version 0.24.

**Returns**

**train_sizes_abs** [array of shape (n_unique_ticks,)] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.

**train_scores** [array of shape (n_ticks, n_cv_folds)] Scores on training sets.

**test_scores** [array of shape (n_ticks, n_cv_folds)] Scores on test set.

**fit_times** [array of shape (n_ticks, n_cv_folds)] Times spent for fitting in seconds. Only present if return_times is True.

**score_times** [array of shape (n_ticks, n_cv_folds)] Times spent for scoring in seconds. Only present if return_times is True.

**Notes**

See `examples/model_selection/plot_learning_curve.py`

**Examples using sklearn.model_selection.learning_curve**

- Comparison of kernel ridge regression and SVR
- Plotting Learning Curves

`skslearn.model_selection.permutation_test_score`

```python
sklearn.model_selection.permutation_test_score(estimator, X, y, *, groups=None, cv=None, n_permutations=100, n_jobs=None, random_state=0, verbose=0, scoring=None, fit_params=None)
```

Evaluate the significance of a cross-validated score with permutations

Permutes targets to generate ‘randomized data’ and compute the empirical p-value against the null hypothesis that features and targets are independent.

The p-value represents the fraction of randomized data sets where the estimator performed as well or better than in the original data. A small p-value suggests that there is a real dependency between features and targets which has been used by the estimator to give good predictions. A large p-value may be due to lack of real dependency between features and targets or the estimator was not able to use the dependency to give good predictions.

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
- **X** [array-like of shape at least 2D] The data to fit.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs) or None] The target variable to try to predict in the case of supervised learning.
groups [array-like of shape (n_samples,), default=None] Labels to constrain permutation within groups, i.e. y values are permuted among samples with the same group identifier. When not specified, y values are permuted among all samples.

When a grouped cross-validator is used, the group labels are also passed on to the split method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.

scoring [str or callable, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

If None the estimator’s score method is used.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- int, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

n_permutations [int, default=100] Number of times to permute y.

n_jobs [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the cross-validated score are parallelized over the permutations. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance or None, default=0] Pass an int for reproducible output for permutation of y values among samples. See Glossary.

verbose [int, default=0] The verbosity level.

fit_params [dict, default=None] Parameters to pass to the fit method of the estimator.

New in version 0.24.

Returns

score [float] The true score without permuting targets.

permutation_scores [array of shape (n_permutations,)] The scores obtained for each permutations.

pvalue [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

\[
\frac{C + 1}{n_{\text{permutations}} + 1}
\]

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.
Notes

This function implements Test 1 in:

Examples using sklearn.model_selection.permutation_test_score

- Test with permutations the significance of a classification score

sklearn.model_selection.validation_curve

sklearn.model_selection.validation_curve(estimator, X, y, *, param_name, param_range, groups=None, cv=None, scoring=None, n_jobs=None, pre_dispatch='all', verbose=0, error_score=nan, fit_params=None)

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the User Guide.

Parameters

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs) or None] Target relative to X for classification or regression; None for unsupervised learning.

- **param_name** [str] Name of the parameter that will be varied.

- **param_range** [array-like of shape (n_values,)] The values of the parameter that will be evaluated.

- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (Stratified)KFold,
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.
Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

scoring [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

n_jobs [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the combinations of each parameter value and each cross-validation split. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

pre_dispatch [int or str, default='all'] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The str can be an expression like ‘2*n_jobs’.

verbose [int, default=0] Controls the verbosity: the higher, the more messages.

fit_params [dict, default=None] Parameters to pass to the fit method of the estimator.

New in version 0.24.

error_score ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.

Returns

train_scores [array of shape (n_ticks, n_cv_folds)] Scores on training sets.

test_scores [array of shape (n_ticks, n_cv_folds)] Scores on test set.

7.27 sklearn.multiclass: Multiclass classification

7.27.1 Multiclass classification strategies

This module implements multiclass learning algorithms:

• one-vs-the-rest / one-vs-all
• one-vs-one
• error correcting output codes

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.
All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a `predict_proba` method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample will not sum to unity, as they do in the single label case.

**User guide:** See the Multiclass classification section for further details.

### 7.27.2 sklearn.multiclass.OneVsRestClassifier

**class sklearn.multiclass.OneVsRestClassifier(**kwargs)**

One-vs-the-rest (OvR) multiclass strategy.

Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is fitted against all the other classes. In addition to its computational efficiency (only n_classes classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.

OneVsRestClassifier can also be used for multilabel classification. To use this feature, provide an indicator matrix for the target y when calling `.fit`. In other words, the target labels should be formatted as a 2D binary (0/1) matrix, where [i, j] == 1 indicates the presence of label j in sample i. This estimator uses the binary relevance method to perform multilabel classification, which involves training one binary classifier independently for each label.

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.
- **n_jobs** [int, default=None] The number of jobs to use for the computation: the n_classes one-vs-rest problems are computed in parallel.

#### Attributes

- **estimators_** [list of n_classes estimators] Estimators used for predictions.
- **coef_** [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function. This attribute exists only if the `estimators_` defines `coef_`.
- **intercept_** [ndarray of shape (1, 1) or (n_classes, 1)] If y is binary, the shape is (1, 1) else (n_classes, 1) This attribute exists only if the `estimators_` defines `intercept_`.
- **classes_** [array, shape = [n_classes]] Class labels.
n_classes_  [int] Number of classes.

label_binarizer_  [LabelBinarizer object] Object used to transform multiclass labels to binary labels and vice-versa.

multilabel_  [boolean] Whether this is a multilabel classifier

See also:

sklearn.multioutput.MultiOutputClassifier  Alternate way of extending an estimator for multilabel classification.

sklearn.preprocessing.MultiLabelBinarizer  Transform iterable of iterables to binary indicator matrix.

Examples

```python
>>> import numpy as np
>>> from sklearn.multiclass import OneVsRestClassifier
>>> from sklearn.svm import SVC

>>> X = np.array([
...    [10, 10],
...    [8, 10],
...    [-5, 5.5],
...    [-5.4, 5.5],
...    [-20, -20],
...    [-15, -20]
...])
>>> y = np.array([0, 0, 1, 1, 2, 2])
>>> clf = OneVsRestClassifier(SVC()).fit(X, y)
>>> clf.predict([[-19, -20], [9, 9], [-5, 5]])
array([2, 0, 1])
```

</tbody>
</table>

decision_function(X)

Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the decision_function method.

Parameters

X  [array-like of shape (n_samples, n_features)]
Returns

T array-like of shape (n_samples, n_classes) or (n_samples,) for binary classification.
Changed in version 0.19: output shape changed to (n_samples,) to conform to scikit-learn conventions for binary classification.

\textbf{fit}(X,y)

Fit underlying estimators.

Parameters

X [(sparse) array-like of shape (n_samples, n_features)] Data.

y [(sparse) array-like of shape (n_samples,) or (n_samples, n_classes)] Multi-class targets.
An indicator matrix turns on multilabel classification.

Returns

self

\textbf{get_params}(\texttt{deep}=True)

Get parameters for this estimator.

Parameters

\texttt{deep} [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

\texttt{params} [dict] Parameter names mapped to their values.

\textbf{property multilabel_}

Whether this is a multilabel classifier

\textbf{partial_fit}(X,y,classes=None)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

Parameters

X [(sparse) array-like of shape (n_samples, n_features)] Data.

y [(sparse) array-like of shape (n_samples,) or (n_samples, n_classes)] Multi-class targets.
An indicator matrix turns on multilabel classification.

\texttt{classes} [array, shape (n_classes,)] Classes across all calls to partial_fit. Can be obtained via \texttt{np.unique(y_all)}, where \texttt{y_all} is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns

self

\textbf{predict}(X)

Predict multi-class targets using underlying estimators.

Parameters

X [(sparse) array-like of shape (n_samples, n_features)] Data.

Returns
y [(sparse) array-like of shape (n_samples,) or (n_samples, n_classes)] Predicted multi-class targets.

**predict_proba** *(X)*
Probability estimates.
The returned estimates for all classes are ordered by label of classes.
Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.
In the single label multiclass case, the rows of the returned matrix sum to 1.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **T** [(sparse) array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** *(X, y, sample_weight=None)*
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of `self.predict(X)` wrt. y.

**set_params** (**params**)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.
Examples using `sklearn.multiclass.OneVsRestClassifier`

- Multilabel classification
- Receiver Operating Characteristic (ROC)
- Precision-Recall
- Classifier Chain

### 7.27.3 `sklearn.multiclass.OneVsOneClassifier`

class `sklearn.multiclass.OneVsOneClassifier(**kwargs)`

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit $n_{\text{classes}} \times (n_{\text{classes}} - 1) / 2$ classifiers, this method is usually slower than one-vs-the-rest, due to its $O(n_{\text{classes}}^2)$ complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don’t scale well with $n_{\text{samples}}$. This is because each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used $n_{\text{classes}}$ times.

Read more in the User Guide.

**Parameters**

- `estimator` [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.
- `n_jobs` [int, default=None] The number of jobs to use for the computation: the $n_{\text{classes}} \times (n_{\text{classes}} - 1) / 2$ OVO problems are computed in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**Attributes**

- `estimators_` [list of $n_{\text{classes}} \times (n_{\text{classes}} - 1) / 2$ estimators] Estimators used for predictions.
- `classes_` [numpay array of shape [n_classes]] Array containing labels.
- `n_classes_` [int] Number of classes
- `pairwise_indices_` [list, length = len(estimators_), or None] Indices of samples used when training the estimators. None when estimator's pairwise tag is False.

Deprecated since version 0.24: The `_pairwise` attribute is deprecated in 0.24. From 0.26 and onward, `pairwise_indices` will use the pairwise estimator tag instead.
Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.multiclass import OneVsOneClassifier
>>> from sklearn.svm import LinearSVC

>>> X, y = load_iris(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, test_size=0.33, shuffle=True, random_state=0)
>>> clf = OneVsOneClassifier(LinearSVC(random_state=0)).fit(X_train, y_train)
>>> clf.predict(X_test[:10])
array([2, 1, 0, 2, 0, 2, 0, 1, 1, 1])
```

**decision_function(X)**

Decision function for the OneVsOneClassifier.

The decision values for the samples are computed by adding the normalized sum of pair-wise classification confidence levels to the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)]

**Returns**

- `Y` [array-like of shape (n_samples, n_classes) or (n_samples,) for binary classification.]

  Changed in version 0.19: output shape changed to (n_samples,) to conform to scikit-learn conventions for binary classification.

**fit(X, y)**

Fit underlying estimators.

**Parameters**

- `X` [(sparse) array-like of shape (n_samples, n_features)] Data.
- `y` [array-like of shape (n_samples,)] Multi-class targets.

**Returns**

- `self`

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- `deep` [Default: True]
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

partial_fit (X, y, classes=None)
Partially fit underlying estimators
Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

Parameters
X [(sparse) array-like of shape (n_samples, n_features)] Data.
y [array-like of shape (n_samples,)] Multi-class targets.
classes [array, shape (n_classes,)] Classes across all calls to partial_fit. Can be obtained via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns
self

predict (X)
Estimate the best class label for each sample in X.
This is implemented as argmax(decision_function(X), axis=1) which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.

Parameters
X [(sparse) array-like of shape (n_samples, n_features)] Data.

Returns
y [numpy array of shape [n_samples]] Predicted multi-class targets.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.27.4 `sklearn.multiclass.OutputCodeClassifier`

class `sklearn.multiclass.OutputCodeClassifier(**kwargs)`

(Non-Correcting) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model (0 < code_size < 1) or for making the model more robust to errors (code_size > 1). See the documentation for more details.

Read more in the `User Guide`.

Parameters

estimator [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.

code_size [float] Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.

random_state [int, RandomState instance, default=None] The generator used to initialize the codebook. Pass an int for reproducible output across multiple function calls. See `Glossary`.

n_jobs [int, default=None] The number of jobs to use for the computation: the multiclass problems are computed in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

Attributes

estimators_ [list of int (n_classes * code_size) estimators] Estimators used for predictions.

classes_ [numpy array of shape [n_classes]] Array containing labels.

code_book_ [numpy array of shape [n_classes, code_size]] Binary array containing the code of each class.

References

[1], [2], [3]
Examples

```python
>>> from sklearn.multiclass import OutputCodeClassifier
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_samples=100, n_features=4,
    ... n_informative=2, n_redundant=0,
    ... random_state=0, shuffle=False)
>>> clf = OutputCodeClassifier(
    ... estimator=RandomForestClassifier(random_state=0),
    ... random_state=0).fit(X, y)
>>> clf.predict([[0, 0, 0, 0]])
array([1])
```
**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

## 7.28 sklearn.multioutput: Multioutput regression and classification

This module implements multioutput regression and classification.

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. The meta-estimator extends single output estimators to multioutput estimators.

**User guide:** See the Multilabel classification, Multiclass-multioutput classification, and Multioutput regression sections for further details.

| multioutput.ClassifierChain(**kwargs) | A multi-label model that arranges binary classifiers into a chain. |
| multioutput.MultiOutputRegressor(**kwargs) | Multi target regression |
| multioutput.MultiOutputClassifier(**kwargs) | Multi target classification |
| multioutput.RegressorChain(**kwargs) | A multi-label model that arranges regressions into a chain. |
7.28.1 sklearn.multioutput.ClassifierChain

class sklearn.multioutput.ClassifierChain(**kwargs)
A multi-label model that arranges binary classifiers into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to
the model plus the predictions of models that are earlier in the chain.

Read more in the User Guide.
New in version 0.19.

Parameters

    base_estimator [estimator] The base estimator from which the classifier chain is built.
    order [array-like of shape (n_outputs,) or ‘random’, default=None] If None, the order will be
determined by the order of columns in the label matrix Y:

        order = [0, 1, 2, ..., Y.shape[1] - 1]

    The order of the chain can be explicitly set by providing a list of integers. For example, for
    a chain of length 5:

        order = [1, 3, 2, 4, 0]

    means that the first model in the chain will make predictions for column 1 in the Y matrix,
    the second model will make predictions for column 3, etc.
    If order is ‘random’ a random ordering will be used.

    cv [int, cross-validation generator or an iterable, default=None] Determines whether to use cross
    validated predictions or true labels for the results of previous estimators in the chain. Possi-
    ble inputs for cv are:

        • None, to use true labels when fitting,
        • integer, to specify the number of folds in a (Stratified)KFold,
        • CV splitter,
        • An iterable yielding (train, test) splits as arrays of indices.

    random_state [int, RandomState instance or None, optional (default=None)] If
    order='random', determines random number generation for the chain order. In
    addition, it controls the random seed given at each base_estimator at each chaining
    iteration. Thus, it is only used when base_estimator exposes a random_state.
    Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

    classes_ [list] A list of arrays of length len(estimators_) containing the class labels for
each estimator in the chain.
    estimators_ [list] A list of clones of base_estimator.
    order_ [list] The order of labels in the classifier chain.

See also:

    RegressorChain Equivalent for regression.
    MultioutputClassifier Classifies each output independently rather than chaining.
References

Examples

```python
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.multioutput import ClassifierChain

>>> X, Y = make_multilabel_classification(...
   n_samples=12, n_classes=3, random_state=0
...)
>>> X_train, X_test, Y_train, Y_test = train_test_split(...
   X, Y, random_state=0
...)
>>> base_lr = LogisticRegression(solver='lbfgs', random_state=0)
>>> chain = ClassifierChain(base_lr, order='random', random_state=0)
>>> chain.fit(X_train, Y_train).predict(X_test)
array([[1., 1., 0.],
       [1., 0., 0.],
       [0., 1., 0.]])
>>> chain.predict_proba(X_test)
array([[0.8387..., 0.9431..., 0.4576...],
       [0.8878..., 0.3684..., 0.2640...],
       [0.0321..., 0.9935..., 0.0625...]])
```

Methods

- `decision_function(X)` Evaluate the decision_function of the models in the chain.
- `fit(X, Y)` Fit the model to data matrix `X` and targets `Y`.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict on the data matrix `X` using the Classifier-Chain model.
- `predict_proba(X)` Predict probability estimates.
- `score(X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(**params)` Set the parameters of this estimator.

### decision_function (X)
Evaluate the decision_function of the models in the chain.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)]

**Returns**

- `Y_decision` [array-like of shape (n_samples, n_classes)] Returns the decision function of the sample for each model in the chain.
Fit the model to data matrix X and targets Y.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.

Y [array-like of shape (n_samples, n_classes)] The target values.

Returns

self [object]

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)

Predict on the data matrix X using the ClassifierChain model.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.

Returns

Y_pred [array-like of shape (n_samples, n_classes)] The predicted values.

predict_proba (X)

Predict probability estimates.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)]

Returns

Y_prob [array-like of shape (n_samples, n_classes)]

score (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.multioutput.ClassifierChain**

- **Classifier Chain**

### 7.28.2 sklearn.multioutput.MultiOutputRegressor

**class** `sklearn.multioutput.MultiOutputRegressor(**kwargs)`

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

New in version 0.18.

**Parameters**

- **estimator** [estimator object] An estimator object implementing `fit` and `predict`.

- **n_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for `fit`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

When individual estimators are fast to train or predict using n_jobs>1 can result in slower performance due to the overhead of spawning processes.

Changed in version 0.20: n_jobs default changed from 1 to None

**Attributes**

- **estimators_** [list of n_output estimators] Estimators used for predictions.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.datasets import load_linnerud
>>> from sklearn.multioutput import MultiOutputRegressor
>>> from sklearn.linear_model import Ridge

>>> X, y = load_linnerud(return_X_y=True)
>>> clf = MultiOutputRegressor(Ridge(random_state=123)).fit(X, y)
>>> clf.predict(X[[0]])
array([[176..., 35..., 57...]])
```

`fit (X, y, sample_weight=None, **fit_params)`

Fit the model to data. Fit a separate model for each output variable.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) Data.
- `y` ([array-like, sparse matrix] of shape (n_samples, n_outputs)) Multi-output targets. An indicator matrix turns on multilabel estimation.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.
- `**fit_params` [dict of string -> object] Parameters passed to the `estimator.fit` method of each step.

**Returns**

- `self` [object]

`get_params (deep=True)`

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

`partial_fit (X, y, sample_weight=None)`

Incrementally fit the model to data. Fit a separate model for each output variable.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) Data.
- `y` ([array-like, sparse matrix] of shape (n_samples, n_outputs)) Multi-output targets.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

- `self` [object]

`predict (X)`
Predict multi-output variable using a model trained for each target variable.

Parameters

Returns

y [array-like, sparse matrix] of shape (n_samples, n_outputs) Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

score (X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction. The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using sklearn.multioutput.MultiOutputRegressor

- Comparing random forests and the multi-output meta estimator

7.28.3 sklearn.multioutput.MultiOutputClassifier

class sklearn.multioutput.MultiOutputClassifier(**kwargs)

Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that
do not natively support multi-target classification

Parameters

estimator [estimator object] An estimator object implementing fit, score and predict_proba.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the com-
putation. It does each target variable in y in parallel. None means 1 unless in a
joblib.parallel_backend context. -1 means using all processors. See Glossary
for more details.

Attributes

classes_ [ndarray of shape (n_classes,)] Class labels.
estimators_ [list of n_output estimators] Estimators used for predictions.

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.multioutput import MultiOutputClassifier
>>> from sklearn.neighbors import KNeighborsClassifier

>>> X, y = make_multilabel_classification(n_classes=3, random_state=0)
>>> clf = MultiOutputClassifier(KNeighborsClassifier()).fit(X, y)
>>> clf.predict(X[-2:]),
array([[1, 1, 0], [1, 1, 1]])
```

Methods

- fit(X, Y, [sample_weight]) Fit the model to data matrix X and targets Y.
- get_params([deep]) Get parameters for this estimator.
- partial_fit(X, y[, classes, sample_weight]) Incrementally fit the model to data.
- predict(X) Predict multi-output variable using a model
- score(X, y) Returns the mean accuracy on the given test data and labels.
- set_params(**params) Set the parameters of this estimator.

```python
>>> fit(X, Y, sample_weight=None, **fit_params)
Fit the model to data matrix X and targets Y.
```

Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

Y  [array-like of shape (n_samples, n_classes)] The target values.

**sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying classifier supports sample weights.

**fit_params**  [dict of string -> object] Parameters passed to the estimator.fit method of each step.

New in version 0.23.

**Returns**

self  [object]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params  [dict] Parameter names mapped to their values.

**partial_fit**(X, y, classes=None, sample_weight=None)

Incrementally fit the model to data. Fit a separate model for each output variable.

**Parameters**

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Data.

y  [[array-like, sparse matrix] of shape (n_samples, n_outputs)] Multi-output targets.

classes  [list of ndarray of shape (n_outputs,)] Each array is unique classes for one output in str/int Can be obtained by via [np.unique(y[:, i]) for i in range(y.shape[1])], where y is the target matrix of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

**sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

self  [object]

**predict**(X)

Predict multi-output variable using a model trained for each target variable.

**Parameters**

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Data.

**Returns**

y  [[array-like, sparse matrix] of shape (n_samples, n_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.
property `predict_proba`
Probability estimates. Returns prediction probabilities for each class of each output.

This method will raise a `ValueError` if any of the estimators do not have `predict_proba`.

Parameters

- `X` [array-like of shape (n_samples, n_features)] Data

Returns

- `p` [array of shape (n_samples, n_classes), or a list of n_outputs such arrays if n_outputs > 1.] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

Changed in version 0.19: This function now returns a list of arrays where the length of the list is n_outputs, and each array is (n_samples, n_classes) for that particular output.

`score`(X, y)
Returns the mean accuracy on the given test data and labels.

Parameters

- `X` [array-like of shape (n_samples, n_features)] Test samples
- `y` [array-like of shape (n_samples, n_outputs)] True values for X

Returns

- `scores` [float] accuracy_score of self.predict(X) versus y

`set_params`(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- `**params` [dict] Estimator parameters.

Returns

### 7.28.4 `sklearn.multioutput.RegressorChain`

class `sklearn.multioutput.RegressorChain`(**kwargs)
A multi-label model that arranges regressions into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the `User Guide`.

New in version 0.20.

Parameters

- `base_estimator` [estimator] The base estimator from which the classifier chain is built.
- `order` [array-like of shape (n_outputs,) or ‘random’, default=’None’] If None, the order will be determined by the order of columns in the label matrix Y.
order = [0, 1, 2, ..., Y.shape[1] - 1]

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5:

order = [1, 3, 2, 4, 0]

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is ‘random’ a random ordering will be used.

cv [int, cross-validation generator or an iterable, default=None] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. Possible inputs for cv are:

- None, to use true labels when fitting,
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

random_state [int, RandomState instance or None, optional (default=None)] If order='random', determines random number generation for the chain order. In addition, it controls the random seed given at each base_estimator at each chaining iteration. Thus, it is only used when base_estimator exposes a random_state. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

- estimators_ [list] A list of clones of base_estimator.
- order_ [list] The order of labels in the classifier chain.

See also:

ClassifierChain Equivalent for classification.

MultioutputRegressor Learns each output independently rather than chaining.

Examples

```python
>>> from sklearn.multioutput import RegressorChain
>>> from sklearn.linear_model import LogisticRegression
>>> logreg = LogisticRegression(solver='lbfgs', multi_class='multinomial')
>>> X, Y = [[1, 0], [0, 1], [1, 1]], [[0, 2], [1, 1], [2, 0]]
>>> chain = RegressorChain(base_estimator=logreg, order=[0, 1]).fit(X, Y)
>>> chain.predict(X)
array([[0., 2.],
       [1., 1.],
       [2., 0.]])
```

**fit (X, Y, **fit_params)**
Fit the model to data matrix X and targets Y.

**Parameters**
- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.
- **Y** [array-like of shape (n_samples, n_classes)] The target values.
- **fit_params** [dict of string -> object] Parameters passed to the fit method at each step of the regressor chain.
  New in version 0.23.

**Returns**
- **self** [object]

**get_params (deep=True)**
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [dict] Parameter names mapped to their values.

**predict (X)**
Predict on the data matrix X using the ClassifierChain model.

**Parameters**
- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.

**Returns**
- **Y_pred** [array-like of shape (n_samples, n_classes)] The predicted values.

**score (X, y, sample_weight=None)**
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())**2).sum()$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] $R^2$ of `self.predict(X)` wrt. y.

**Notes**

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### 7.29 sklearn.naive_bayes: Naive Bayes

The *sklearn.naive_bayes* module implements Naive Bayes algorithms. These are supervised learning methods based on applying Bayes’ theorem with strong (naive) feature independence assumptions.

**User guide:** See the *Naive Bayes* section for further details.

| naive_bayes.CategoricalNB(**kwargs) | Naive Bayes classifier for categorical features |
| naive_bayes.ComplementNB(**kwargs) | The Complement Naive Bayes classifier described in Rennie et al. |
| naive_bayes.GaussianNB(**kwargs) | Gaussian Naive Bayes (GaussianNB) |
| naive_bayes.MultinomialNB(**kwargs) | Naive Bayes classifier for multinomial models |
7.29.1 sklearn.naive_bayes.BernoulliNB

class sklearn.naive_bayes.BernoulliNB(**kwargs)

Naive Bayes classifier for multivariate Bernoulli models.

Like MultinomialNB, this classifier is suitable for discrete data. The difference is that while MultinomialNB works with occurrence counts, BernoulliNB is designed for binary/boolean features.

Read more in the User Guide.

Parameters

alpha [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

binarize [float or None, default=0.0] Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.

fit_prior [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

class_prior [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes

class_count_ [ndarray of shape (n_classes)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [ndarray of shape (n_classes)] Log probability of each class (smoothed).

classes_ [ndarray of shape (n_classes,)] Class labels known to the classifier

coef_ [ndarray of shape (n_classes, n_features)] Mirrors feature_log_prob_ for interpreting BernoulliNB as a linear model.

feature_count_ [ndarray of shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

feature_log_prob_ [ndarray of shape (n_classes, n_features)] Empirical log probability of features given a class, P(x_j|y).

intercept_ [ndarray of shape (n_classes,)] Mirrors class_log_prior_ for interpreting BernoulliNB as a linear model.

n_features_ [int] Number of features of each sample.

References

### Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> Y = np.array([1, 2, 3, 4, 4, 5])
>>> from sklearn.naive_bayes import BernoulliNB
>>> clf = BernoulliNB()
>>> clf.fit(X, Y)
BernoulliNB()
>>> print(clf.predict(X[2:3]))
[3]
```
This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values.
- **classes** [array-like of shape (n_classes), default=None] List of all the classes that can possibly appear in the y vector.
  
  Must be provided at the first call to partial_fit, can be omitted in subsequent calls.
- **sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

- **self** [object]

**predict (X)**

Perform classification on an array of test vectors X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba (X)**

Return log-probability estimates for the test vector X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict_proba (X)**

Return probability estimates for the test vector X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score (X, y, sample_weight=None)**

Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.naive_bayes.BernoulliNB**

- Hashing feature transformation using Totally Random Trees
- Classification of text documents using sparse features

**7.29.2 sklearn.naive_bayes.CategoricalNB**

**class sklearn.naive_bayes.CategoricalNB(**kwargs**)

Naive Bayes classifier for categorical features

The categorical Naive Bayes classifier is suitable for classification with discrete features that are categorically distributed. The categories of each feature are drawn from a categorical distribution. Read more in the User Guide.

**Parameters**

- **alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- **fit_prior** [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- **class_prior** [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.
- **min_categories** [int or array-like of shape (n_features,), default=None] Minimum number of categories per feature.
  
  • integer: Sets the minimum number of categories per feature to n_categories for each features.
• array-like: shape (n_features,) where n_categories[i] holds the minimum number of categories for the ith column of the input.

• None (default): Determines the number of categories automatically from the training data.

New in version 0.24.

Attributes

category_count_ [list of arrays of shape (n_features,)] Holds arrays of shape (n_classes, n_categories of respective feature) for each feature. Each array provides the number of samples encountered for each class and category of the specific feature.

class_count_ [ndarray of shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [ndarray of shape (n_classes,)] Smoothed empirical log probability for each class.

classes_ [ndarray of shape (n_classes,)] Class labels known to the classifier

feature_log_prob_ [list of arrays of shape (n_features,)] Holds arrays of shape (n_classes, n_categories of respective feature) for each feature. Each array provides the empirical log probability of categories given the respective feature and class, P(x_i|y).

n_features_ [int] Number of features of each sample.

n_categories_ [ndarray of shape (n_features,), dtype=int] Number of categories for each feature. This value is inferred from the data or set by the minimum number of categories.

New in version 0.24.

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import CategoricalNB
>>> clf = CategoricalNB()
>>> clf.fit(X, y)
CategoricalNB()
>>> print(clf.predict(X[2:3]))
[3]
```

| set_params(**params) | Set the parameters of this estimator. |

**fit** *(X, y, sample_weight=None)*

Fit Naive Bayes classifier according to X, y

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* Training vectors, where
  - n_samples is the number of samples and n_features is the number of features. Here, each feature of X is assumed to be from a different categorical distribution. It is further assumed that all categories of each feature are represented by the numbers 0, . . . , n - 1, where n refers to the total number of categories for the given feature. This can, for instance, be achieved with the help of OrdinalEncoder.
- **y** *(array-like of shape (n_samples,))* Target values.
- **sample_weight** *(array-like of shape (n_samples), default=None)* Weights applied to individual samples (1. for unweighted).

**Returns**

- **self** *(object)*

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** *(bool, default=True)* If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** *(dict)* Parameter names mapped to their values.

**partial_fit** *(X, y, classes=None, sample_weight=None)*

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* Training vectors, where
  - n_samples is the number of samples and n_features is the number of features. Here, each feature of X is assumed to be from a different categorical distribution. It is further assumed that all categories of each feature are represented by the numbers 0, . . . , n - 1, where n refers to the total number of categories for the given feature. This can, for instance, be achieved with the help of OrdinalEncoder.
- **y** *(array-like of shape (n_samples,))* Target values.
- **classes** *(array-like of shape (n_classes), default=None)* List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.
**sample_weight** [array-like of shape (n_samples), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

self [object]

**predict** *(X)*

Perform classification on an array of test vectors X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

C [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba** *(X)*

Return log-probability estimates for the test vector X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**predict_proba** *(X)*

Return probability estimates for the test vector X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of self.predict (X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.**

Returns

self [estimator instance] Estimator instance.

7.29.3 sklearn.naive_bayes.ComplementNB

**class sklearn.naive_bayes.ComplementNB(**kwargs)\n**

The Complement Naive Bayes classifier described in Rennie et al. (2003).

The Complement Naive Bayes classifier was designed to correct the “severe assumptions” made by the standard Multinomial Naive Bayes classifier. It is particularly suited for imbalanced data sets.

Read more in the User Guide.

New in version 0.20.

Parameters

alpha [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

fit_prior [bool, default=True] Only used in edge case with a single class in the training set.

class_prior [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. Not used.

norm [bool, default=False] Whether or not a second normalization of the weights is performed. The default behavior mirrors the implementations found in Mahout and Weka, which do not follow the full algorithm described in Table 9 of the paper.

Attributes

class_count_ [ndarray of shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [ndarray of shape (n_classes,)] Smoothed empirical log probability for each class. Only used in edge case with a single class in the training set.

classes_ [ndarray of shape (n_classes,)] Class labels known to the classifier

coef_ [ndarray of shape (n_classes, n_features)] Mirrors feature_log_prob_ for interpreting ComplementNB as a linear model.

Deprecated since version 0.24: coef_ is deprecated in 0.24 and will be removed in 0.26.

feature_all_ [ndarray of shape (n_features,)] Number of samples encountered for each feature during fitting. This value is weighted by the sample weight when provided.

feature_count_ [ndarray of shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

feature_log_prob_ [ndarray of shape (n_classes, n_features)] Empirical weights for class complements.
scikit-learn user guide, Release 0.24.dev0

*intercept_* [ndarray of shape (n_classes,)] Mirrors `class_log_prior_` for interpreting ComplementNB as a linear model. Deprecated since version 0.24: `coef_` is deprecated in 0.24 and will be removed in 0.26.

*n_features_* [int] Number of features of each sample.

References

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import ComplementNB
>>> clf = ComplementNB()
>>> clf.fit(X, y)
ComplementNB()
>>> print(clf.predict(X[2:3]))
[3]
```

Methods

**fit**(X, y[, sample_weight]) Fit Naive Bayes classifier according to X, y

**get_params**(deep) Get parameters for this estimator.

**partial_fit**(X, y[, classes, sample_weight]) Incremental fit on a batch of samples.

**predict**(X) Perform classification on an array of test vectors X.

**predict_log_proba**(X) Return log-probability estimates for the test vector X.

**predict_proba**(X) Return probability estimates for the test vector X.

**score**(X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.

**set_params**(**params) Set the parameters of this estimator.

**fit**(X, y, sample_weight=None)

Fit Naive Bayes classifier according to X, y

**Parameters**

X [array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

self [object]
get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

partial_fit (X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to
implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are
as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where
n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

classes [array-like of shape (n_classes), default=None] List of all the classes that can possi-
bly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to indi-
vidual samples (1. for unweighted).

Returns

self [object]

predict (X)
Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X

predict_log_proba (X)
Return log-probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples
for each class in the model. The columns correspond to the classes in sorted order, as they
appear in the attribute classes_.

2524 Chapter 7. API Reference
predict_proba \((X)\)  
Return probability estimates for the test vector \(X\).

**Parameters**

\(X\) [array-like of shape (n_samples, n_features)]

**Returns**

\(C\) [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute \(\text{classes}_.\)

score \((X, y, sample\_weight=None)\)  
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

\(X\) [array-like of shape (n_samples, n_features)] Test samples.

\(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).

\(sample\_weight\) [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

\(score\) [float] Mean accuracy of \(self.predict(X)\) wrt. \(y\).

set_params (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<\text{component}>_.<\text{parameter}>\) so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

\(self\) [estimator instance] Estimator instance.

Examples using sklearn.naive_bayes.ComplementNB

- Classification of text documents using sparse features

7.29.4 sklearn.naive_bayes.GaussianNB

class sklearn.naive_bayes.GaussianNB (**kwargs)  
Gaussian Naive Bayes (GaussianNB)

Can perform online updates to model parameters via \(\text{partial\_fit}\). For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:

Read more in the User Guide.

Parameters
**priors** [array-like of shape (n_classes,)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**var_smoothing** [float, default=1e-9] Portion of the largest variance of all features that is added to variances for calculation stability.

New in version 0.20.

**Attributes**

- **class_count** [ndarray of shape (n_classes,)] number of training samples observed in each class.
- **class_prior** [ndarray of shape (n_classes,)] probability of each class.
- **classes** [ndarray of shape (n_classes,)] class labels known to the classifier
- **epsilon** [float] absolute additive value to variances
- **sigma** [ndarray of shape (n_classes, n_features)] variance of each feature per class
- **theta** [ndarray of shape (n_classes, n_features)] mean of each feature per class

**Examples**

```python
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB()
>>> print(clf.predict([[-0.8, -1]]))
[1]
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB()
>>> print(clf_pf.predict([[-0.8, -1]]))
[1]
```

**Methods**

- `fit(X, y[, sample_weight])` Fit Gaussian Naive Bayes according to X, y
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, classes, sample_weight])` Incremental fit on a batch of samples.
- `predict(X)` Perform classification on an array of test vectors X.
- `predict_log_proba(X)` Return log-probability estimates for the test vector X.
- `predict_proba(X)` Return probability estimates for the test vector X.
- `score(X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(**params)` Set the parameters of this estimator.

**fit(X, y, sample_weight=None)**

Fit Gaussian Naive Bayes according to X, y

**Parameters**
X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

New in version 0.17: Gaussian Naive Bayes supports fitting with sample_weight.

Returns

self [object]

get_params (deep=True)

Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

partial_fit (X, y, classes=None, sample_weight=None)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

classes [array-like of shape (n_classes,), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

New in version 0.17.

Returns

self [object]

predict (X)

Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X
**predict_log_proba** *(X)*
Return log-probability estimates for the test vector X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict_proba** *(X)*
Return probability estimates for the test vector X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** *(X, y, sample_weight=None)*
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.
Examples using `sklearn.naive_bayes.GaussianNB`

- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Probability calibration of classifiers
- Classifier comparison
- Plot class probabilities calculated by the VotingClassifier
- Plotting Learning Curves
- Importance of Feature Scaling

7.29.5 `sklearn.naive_bayes.MultinomialNB`

class `sklearn.naive_bayes.MultinomialNB(**kwargs)`

Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the User Guide.

Parameters

- `alpha` [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- `fit_prior` [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- `class_prior` [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes

- `class_count_` [ndarray of shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- `class_log_prior_` [ndarray of shape (n_classes,)] Smoothed empirical log probability for each class.
- `classes_` [ndarray of shape (n_classes,)] Class labels known to the classifier
- `coef_` [ndarray of shape (n_classes, n_features)] Mirrors `feature_log_prob_` for interpreting MultinomialNB as a linear model.
  
  Deprecated since version 0.24: `coef_` is deprecated in 0.24 and will be removed in 0.26.

- `feature_count_` [ndarray of shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
- `feature_log_prob_` [ndarray of shape (n_classes, n_features)] Empirical log probability of features given a class, \( P(x_i | y) \).
- `intercept_` [ndarray of shape (n_classes,)] Mirrors `class_log_prior_` for interpreting MultinomialNB as a linear model.
Deprecation warning: `intercept_` is deprecated in 0.24 and will be removed in 0.26.

**n_features**  [int] Number of features of each sample.

**Notes**

For the rationale behind the names `coef_` and `intercept_`, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.

**Examples**

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
MultinomialNB()
>>> print(clf.predict(X[2:3]))
[3]
```

</tbody>
</table>

**fit(X, y, sample_weight=None)**

Fit Naive Bayes classifier according to X, y

**Parameters**

- `X`  [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y`  [array-like of shape (n_samples,)] Target values.
**sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**
self [object]

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**partial_fit** *(X, y, classes=None, sample_weight=None)*
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples,)] Target values.

- **classes** [array-like of shape (n_classes), default=None] List of all the classes that can possibly appear in the y vector.

  Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

- **sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**
self [object]

**predict** *(X)*
Perform classification on an array of test vectors X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba** *(X)*
Return log-probability estimates for the test vector X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**
C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict_proba** *(X)*

Return probability estimates for the test vector X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of `self.predict(X)` wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using** `sklearn.naive_bayes.MultinomialNB`

- Out-of-core classification of text documents
- Classification of text documents using sparse features
The `sklearn.neighbors` module implements the k-nearest neighbors algorithm.

**User guide:** See the *Nearest Neighbors* section for further details.

```python
def BallTree(X, leaf_size=40, metric='minkowski', **kwargs):
    BallTree for fast generalized N-point problems
```

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

- **leaf_size** [positive int, default=40] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

- **metric** [str or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball_tree.valid_metrics gives a list of the metrics which are valid for BallTree.

Additional keywords are passed to the distance metric class.

**Note:** Callable functions in the metric parameter are NOT supported for KDTree and Ball Tree. Function call overhead will result in very poor performance.
Attributes

data [memory view] The training data

Examples

Query for k-nearest neighbors

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```python
>>> import numpy as np
>>> import pickle

>>> rng = np.random.RandomState(0)

>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)

>>> s = pickle.dumps(tree)

>>> tree_copy = pickle.loads(s)

>>> dist, ind = tree_copy.query(X[:1], k=3)

>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[0. 0.19662693 0.29473397]
```

Query for neighbors within a given radius

```python
>>> import numpy as np

>>> rng = np.random.RandomState(0)

>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions

>>> tree = BallTree(X, leaf_size=2)

>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3

>>> ind = tree.query_radius(X[:1], r=0.3)

>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```python
>>> import numpy as np

>>> rng = np.random.RandomState(42)

>>> X = rng.random_sample((100, 3))

>>> tree = BallTree(X)

>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649, 7.83281226, 7.2071716 ])
```

Compute a two-point auto-correlation function
```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BallTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30, 62, 278, 580, 820])
```

</tbody>
</table>

#### get_arrays (self)

Get data and node arrays.

**Returns**

arrays: tuple of array  
Arrays for storing tree data, index, node data and node bounds.

#### get_n_calls (self)

Get number of calls.

**Returns**

n_calls: int  
number of distance computation calls

#### get_tree_stats (self)

Get tree status.

**Returns**

tree_stats: tuple of int  
(number of trims, number of leaves, number of splits)

#### kernel_density (self, X, h[, kernel, atol, ...])

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

**Parameters**

- X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
- h [float] the bandwidth of the kernel
- kernel [str, default="gaussian"] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’
- atol, rtol [float, default=0, 1e-8] Specify the desired relative and absolute tolerance of the result. If the true result is K_true, then the returned result K_ret satisfies abs(K_ret - K_true) <= atol + rtol * abs(K_true)
- \( K_{\text{ret}} < \text{atol} + \text{rtol} \times K_{\text{ret}} \) The default is zero (i.e. machine precision) for both.

- **breadth_first** [bool, default=False] If True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

- **return_log** [bool, default=False] Return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

**Returns**

- **density** [ndarray of shape X.shape[:-1]] The array of (log)-density evaluations

**query** \((X, k=1, \text{return_distance=}\text{True}, \text{dualtree=}\text{False}, \text{breadth_first=}\text{False})\)

query the tree for the \(k\) nearest neighbors

**Parameters**

- **X** [array-like of shape \((n\_samples, n\_features)\)] An array of points to query

- **k** [int, default=1] The number of nearest neighbors to return

- **return_distance** [bool, default=True] if True, return a tuple \((d, i)\) of distances and indices if False, return array \(i\)

- **dualtree** [bool, default=False] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

- **breadth_first** [bool, default=False] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

- **sort_results** [bool, default=True] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

**Returns**

- \(i\) [if \(\text{return_distance} = \text{False}\)]

- **(d, i)** [if \(\text{return_distance} = \text{True}\)]

- **d** [ndarray of shape \(X\).shape[:-1] + k, dtype=double] Each entry gives the list of distances to the neighbors of the corresponding point.

- **i** [ndarray of shape \(X\).shape[:-1] + k, dtype=int] Each entry gives the list of indices of neighbors of the corresponding point.

**query_radius** \((X, r, \text{return_distance=}\text{False}, \text{count_only=}\text{False}, \text{sort_results=}\text{False})\)

query the tree for neighbors within a radius \(r\)

**Parameters**

- **X** [array-like of shape \((n\_samples, n\_features)\)] An array of points to query

- **r** [distance within which neighbors are returned] \(r\) can be a single value, or an array of values of shape \(x\).shape[:-1] if different radii are desired for each point.

- **return_distance** [bool, default=False] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting \(\text{return_distance=}\text{True}\) here adds to the computation time. Not all distances need to be calculated explicitly for \(\text{return_distance=}\text{False}\). Results are not sorted by default: see \(\text{sort_results}\) keyword.
count_only [bool, default=False] if True, return only the count of points within distance r If False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

sort_results [bool, default=False] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns

count [if count_only == True]
ind [if count_only == False and return_distance == False]
(ind, dist) [if count_only == False and return_distance == True]
count [ndarray of shape X.shape[:-1], dtype=int] Each entry gives the number of neighbors within a distance r of the corresponding point.
ind [ndarray of shape X.shape[:-1], dtype=object] Each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.
dist [ndarray of shape X.shape[:-1], dtype=object] Each element is a numpy double array listing the distances corresponding to indices in i.

reset_n_calls (self)
Reset number of calls to 0.

two_point_correlation (X, r, dualtree=False)
Compute the two-point correlation function

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
r [array-like] A one-dimensional array of distances
dualtree [bool, default=False] If True, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns

counts [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

7.30.2 sklearn.neighbors.DistanceMetric

class sklearn.neighbors.DistanceMetric
DistanceMetric class

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the get_metric class method and the metric string identifier (see below).
Examples

```python
>>> from sklearn.neighbors import DistanceMetric
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2],
...     [3, 4, 5]]
>>> dist.pairwise(X)
array([[ 0.00000000,  5.19615242],
       [ 5.19615242,  0.00000000]])
```

Available Metrics

The following lists the string metric identifiers and the associated distance metric classes:

**Metrics intended for real-valued vector spaces:**

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>args</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“euclidean”</td>
<td>EuclideanDistance</td>
<td>•</td>
<td><code>sqrt(sum((x - y)^2))</code></td>
</tr>
<tr>
<td>“manhattan”</td>
<td>ManhattanDistance</td>
<td>•</td>
<td>`sum(</td>
</tr>
<tr>
<td>“chebyshev”</td>
<td>ChebyshevDistance</td>
<td>•</td>
<td>`max(</td>
</tr>
<tr>
<td>“minkowski”</td>
<td>MinkowskiDistance</td>
<td>p</td>
<td>`sum(</td>
</tr>
<tr>
<td>“wminkowski”</td>
<td>WMinkowskiDistance</td>
<td>p, w</td>
<td>`sum(</td>
</tr>
<tr>
<td>“seuclidean”</td>
<td>SEuclideanDistance</td>
<td>V</td>
<td><code>sqrt(sum((x - y)^2 / V))</code></td>
</tr>
<tr>
<td>“mahalanobis”</td>
<td>MahalanobisDistance</td>
<td>V or VI</td>
<td><code>sqrt((x - y)' V^-1 (x - y))</code></td>
</tr>
</tbody>
</table>

**Metrics intended for two-dimensional vector spaces:** Note that the haversine distance metric requires data in the form of [latitude, longitude] and both inputs and outputs are in units of radians.

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“haversine”</td>
<td>HaversineDistance</td>
<td><code>2 arcsin(sqrt(sin^2(0.5*dx) + cos(x1)cos(x2)sin^2(0.5*dy)))</code></td>
</tr>
</tbody>
</table>

**Metrics intended for integer-valued vector spaces:** Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“hamming”</td>
<td>HammingDistance</td>
<td><code>N_unequal(x, y) / N_tot</code></td>
</tr>
<tr>
<td>“canberra”</td>
<td>CanberraDistance</td>
<td>`sum(</td>
</tr>
<tr>
<td>“braycurtis”</td>
<td>BrayCurtisDistance</td>
<td>`sum(</td>
</tr>
</tbody>
</table>

**Metrics intended for boolean-valued vector spaces:** Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- `N` : number of dimensions
• NTT : number of dims in which both values are True
• NTF : number of dims in which the first value is True, second is False
• NFT : number of dims in which the first value is False, second is True
• NFF : number of dims in which both values are False
• NNEQ : number of non-equal dimensions, NNEQ = NTF + NFT
• NNZ : number of nonzero dimensions, NNZ = NTF + NFT + NTT

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;jaccard&quot;</td>
<td>JaccardDistance</td>
<td>NNEQ / NNZ</td>
</tr>
<tr>
<td>&quot;matching&quot;</td>
<td>MatchingDistance</td>
<td>NNEQ / N</td>
</tr>
<tr>
<td>&quot;dice&quot;</td>
<td>DiceDistance</td>
<td>NNEQ / (NTT + NNZ)</td>
</tr>
<tr>
<td>&quot;kulsinski&quot;</td>
<td>KulsinskiDistance</td>
<td>(NNEQ + N - NTT) / (NNEQ + N)</td>
</tr>
<tr>
<td>&quot;rogerstanimoto&quot;</td>
<td>RogersTanimotoDistance</td>
<td>2 * NNEQ / (N + NNEQ)</td>
</tr>
<tr>
<td>&quot;russellrao&quot;</td>
<td>RussellRaoDistance</td>
<td>NNZ / N</td>
</tr>
<tr>
<td>&quot;sokalmichener&quot;</td>
<td>SokalMichenerDistance</td>
<td>2 * NNEQ / (N + NNEQ)</td>
</tr>
<tr>
<td>&quot;sokalsneath&quot;</td>
<td>SokalSneathDistance</td>
<td>NNEQ / (NNEQ + 0.5 * NTT)</td>
</tr>
</tbody>
</table>

User-defined distance:

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>args</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pyfunc&quot;</td>
<td>PyFuncDistance</td>
<td>func</td>
</tr>
</tbody>
</table>

Here `func` is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the BallTree, the distance must be a true metric: i.e. it must satisfy the following properties

1) Non-negativity: \( d(x, y) \geq 0 \)
2) Identity: \( d(x, y) = 0 \) if and only if \( x = y \)
3) Symmetry: \( d(x, y) = d(y, x) \)
4) Triangle Inequality: \( d(x, y) + d(y, z) \geq d(x, z) \)

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

Methods

<table>
<thead>
<tr>
<th>method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dist_to_rdist</td>
<td>Convert the true distance to the reduced distance.</td>
</tr>
<tr>
<td>get_metric</td>
<td>Get the given distance metric from the string identifier.</td>
</tr>
<tr>
<td>pairwise</td>
<td>Compute the pairwise distances between X and Y</td>
</tr>
<tr>
<td>rdist_to_dist</td>
<td>Convert the Reduced distance to the true distance.</td>
</tr>
</tbody>
</table>

**dist_to_rdist()**

Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.
get_metric()
Get the given distance metric from the string identifier.
See the docstring of DistanceMetric for a list of available metrics.

Parameters
metric [string or class name] The distance metric to use
**kwargs additional arguments will be passed to the requested metric

pairwise()
Compute the pairwise distances between X and Y
This is a convenience routine for the sake of testing. For many metrics, the utilities in
scipy.spatial.distance.cdist and scipy.spatial.distance.pdist will be faster.

Parameters
X [array-like] Array of shape (Nx, D), representing Nx points in D dimensions.
Y [array-like (optional)] Array of shape (Ny, D), representing Ny points in D dimensions. If
not specified, then Y=X.

Returns
——-
dist [ndarray] The shape (Nx, Ny) array of pairwise distances between points in X and Y.

rdist_to_dist()
Convert the Reduced distance to the true distance.
The reduced distance, defined for some metrics, is a computationally more efficient measure which pre-
serves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is
the squared-euclidean distance.

7.30.3 sklearn.neighbors.KDTree
class sklearn.neighbors.KDTree (X, leaf_size=40, metric='minkowski', **kwargs)
KDTree for fast generalized N-point problems
Read more in the User Guide.

Parameters
X [array-like of shape (n_samples, n_features)] n_samples is the number of points in the data
set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous
array of doubles then data will not be copied. Otherwise, an internal copy will be made.

leaf_size [positive int, default=40] Number of points at which to switch to brute-force. Chang-
ing leaf_size will not affect the results of a query, but can significantly impact the speed
of a query and the memory required to store the constructed tree. The amount of mem-
ory needed to store the tree scales as approximately n_samples / leaf_size. For a specified
leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 *
leaf_size, except in the case that n_samples < leaf_size.

metric [str or DistanceMetric object] the distance metric to use for the tree. De-
fault='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the
DistanceMetric class for a list of available metrics. kd_tree.valid_metrics gives a list of the
metrics which are valid for KDTree.

Additional keywords are passed to the distance metric class.
Callable functions in the metric parameter are NOT supported for KDTree
and Ball Tree. Function call overhead will result in very poor performance.

Attributes

data [memory view] The training data

Examples

Query for k-nearest neighbors

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be
rebuilt upon unpickling.

```python
>>> import numpy as np
>>> import pickle

>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Query for neighbors within a given radius

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```python
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = KDTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([6.94114649, 7.83281226, 7.2071716])
```

7.30. sklearn.neighbors: Nearest Neighbors
Compute a two-point auto-correlation function

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = KDTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30, 62, 278, 580, 820])
```

### `get_arrays(self)`
Get data and node arrays.

**Returns**

arrays: tuple of array  Arrays for storing tree data, index, node data and node bounds.

### `get_n_calls(self)`
Get number of calls.

**Returns**

n_calls: int  number of distance computation calls

### `get_tree_stats(self)`
Get tree status.

**Returns**

tree_stats: tuple of int  (number of trims, number of leaves, number of splits)

### `kernel_density(self, X, h[, kernel, atol, ...])`
Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

**Parameters**

- X  [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
- h  [float] the bandwidth of the kernel
- kernel  [str, default=’gaussian’] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’
atol, rtol [float, default=0, 1e-8] Specify the desired relative and absolute tolerance of the result. If the true result is $K_{true}$, then the returned result $K_{ret}$ satisfies $\text{abs}(K_{true} - K_{ret}) < atol + rtol \times K_{ret}$ The default is zero (i.e. machine precision) for both.

breadth_first [bool, default=False] If True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

return_log [bool, default=False] Return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns

density [ndarray of shape X.shape[-1]] The array of (log)-density evaluations

query $(X, k=1, return_distance=True, dualtree=False, breadth_first=False)$
query the tree for the k nearest neighbors

Parameters

$X$ [array-like of shape (n_samples, n_features)] An array of points to query

$k$ [int, default=1] The number of nearest neighbors to return

return_distance [bool, default=True] if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree [bool, default=False] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first [bool, default=False] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results [bool, default=True] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns

i [if return_distance == False]

(d,i) [if return_distance == True]

d [ndarray of shape X.shape[-1] + k, dtype=double] Each entry gives the list of distances to the neighbors of the corresponding point.

i [ndarray of shape X.shape[-1] + k, dtype=int] Each entry gives the list of indices of neighbors of the corresponding point.

query_radius $(X, r, return_distance=False, count_only=False, sort_results=False)$
query the tree for neighbors within a radius r

Parameters

$X$ [array-like of shape (n_samples, n_features)] An array of points to query

$r$ [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[-1] if different radii are desired for each point.

return_distance [bool, default=False] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be
calculated explicitly for return_distance=False. Results are not sorted by default: see sort_results keyword.

count_only [bool, default=False] if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

sort_results [bool, default=False] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns

count [if count_only == True]
ind [if count_only == False and return_distance == False]
(ind, dist) [if count_only == False and return_distance == True]

count [ndarray of shape X.shape[:-1], dtype=int] Each entry gives the number of neighbors within a distance r of the corresponding point.
ind [ndarray of shape X.shape[:-1], dtype=object] Each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

dist [ndarray of shape X.shape[:-1], dtype=object] Each element is a numpy double array listing the distances corresponding to indices in i.

reset_n_calls (self)
Reset number of calls to 0.

two_point_correlation (X, r, dualtree=False)
Compute the two-point correlation function

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
r [array-like] A one-dimensional array of distances
dualtree [bool, default=False] If True, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns

counts [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

7.30.4 sklearn.neighbors.KernelDensity

class sklearn.neighbors.KernelDensity (**kwargs)
Kernel Density Estimation.

Read more in the User Guide.

Parameters

bandwidth [float, default=1.0] The bandwidth of the kernel.
algorithm [{‘kd_tree’, ‘ball_tree’, ‘auto’}, default=’auto’] The tree algorithm to use.

**metric** [str, default=’euclidean’) The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of BallTree and KDTree for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is ‘euclidean’.

**atol** [float, default=0] The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution.

**rtol** [float, default=0] The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution.

**breadth_first** [bool, default=True] If true (default), use a breadth-first approach to the problem. Otherwise use a depth-first approach.

**leaf_size** [int, default=40] Specify the leaf size of the underlying tree. See BallTree or KDTree for details.

**metric_params** [dict, default=None] Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of BallTree or KDTree.

**Attributes**

**tree_** [BinaryTree instance] The tree algorithm for fast generalized N-point problems.

**See also:**

sklearn.neighbors.KDTree K-dimensional tree for fast generalized N-point problems.

sklearn.neighbors.BallTree Ball tree for fast generalized N-point problems.

**Examples**

Compute a gaussian kernel density estimate with a fixed bandwidth.

```python
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> kde = KernelDensity(kernel='gaussian', bandwidth=0.5).fit(X)
>>> log_density = kde.score_samples(X[:3])
>>> log_density
array([-1.52955942, -1.51462041, -1.60244657])
```

**Methods**

</tbody>
</table>

**fit** (X, y=None, sample_weight=None)
Fit the Kernel Density model on the data.

Parameters

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
- **y** [None] Ignored. This parameter exists only for compatibility with **Pipeline**.
- **sample_weight** [array-like of shape (n_samples,), default=None] List of sample weights attached to the data X.
  
  New in version 0.20.

Returns

- **self** [object] Returns instance of object.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**sample**(n_samples=1, random_state=None)

Generate random samples from the model.

Currently, this is implemented only for gaussian and tophat kernels.

Parameters

- **n_samples** [int, default=1] Number of samples to generate.
- **random_state** [int, RandomState instance or None, default= None] Determines random number generation used to generate random samples. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

Returns

- **X** [array-like of shape (n_samples, n_features)] List of samples.

**score**(X, y=None)

Compute the total log probability density under the model.

Parameters

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
- **y** [None] Ignored. This parameter exists only for compatibility with **Pipeline**.

Returns

- **logprob** [float] Total log-likelihood of the data in X. This is normalized to be a probability density, so the value will be low for high-dimensional data.

**score_samples**(X)

Evaluate the log density model on the data.

Parameters
X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data (n_features).

Returns

density [ndarray of shape (n_samples,)] The array of log(density) evaluations. These are normalized to be probability densities, so values will be low for high-dimensional data.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.neighbors.KernelDensity

• Kernel Density Estimation
• Kernel Density Estimate of Species Distributions
• Simple 1D Kernel Density Estimation

7.30.5 sklearn.neighbors.KNeighborsClassifier

class sklearn.neighbors.KNeighborsClassifier(**kwargs)
Classifier implementing the k-nearest neighbors vote.

Read more in the User Guide.

Parameters

n_neighbors [int, default=5] Number of neighbors to use by default for kneighbors queries.

weights [{‘uniform’, ‘distance’} or callable, default=’uniform’] weight function used in pre-
diction. Possible values:

• ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.

• ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.

• [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=’auto’] Algorithm used to compute the nearest neighbors:

• ‘ball_tree’ will use BallTree

• ‘kd_tree’ will use KDTree

• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed
to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of
the construction and query, as well as the memory required to store the tree. The optimal
value depends on the nature of the problem.

p [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent
to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p,
minkowski_distance (l_p) is used.

metric [str or callable, default='minkowski'] the distance metric to use for the tree. The default
metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the
documentation of DistanceMetric for a list of available metrics. If metric is “precom-
puted”, X is assumed to be a distance matrix and must be square during fit. X may be a
sparse graph, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None
means 1 unless in a joblib.parallel_backend context. -1 means using all proces-
sors. See Glossary for more details. Doesn’t affect fit method.

Attributes

classes_ [array of shape (n_classes,)] Class labels known to the classifier

effective_metric_ [str or callable] The distance metric used. It will be same as the metric
parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’
and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For
most metrics will be same with metric_params parameter, but may also contain the p
parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

outputs_2d_ [bool] False when y’s shape is (n_samples,) or (n_samples, 1) during fit otherwise
True.

Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor k+1 and k, have identical distances but different labels, the results will depend on the ordering of the training data.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[0.66666667 0.33333333]]
```

</table>

**fit(X, y)**

Fit the k-nearest neighbors classifier from the training dataset.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed')] Training data.
- **y** [(array-like, sparse matrix) of shape (n_samples,) or (n_samples, n_outputs)] Target values.

**Returns**

- **self** [KNeighborsClassifier] The fitted k-nearest neighbors classifier.
get_params (deep=True)
Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

kneighbors (X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters

- X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- n_neighbors [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.
- return_distance [bool, default=True] Whether or not to return the distances.

Returns

- neigh_dist [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True
- neigh_ind [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1], [2]])
```

kneighbors_graph (X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters
**X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric=’precomputed’ the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

**n_neighbors** [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

**mode** [‘connectivity’, ‘distance’], default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

See also:

*NearestNeighbors.radius_neighbors_graph*

**Examples**

```python
generate_surface.py  >>> X = [[0], [3], [1]] >>> from sklearn.neighbors import NearestNeighbors >>> neigh = NearestNeighbors(n_neighbors=2) >>> neigh.fit(X) NearestNeighbors(n_neighbors=2) >>> A = neigh.kneighbors_graph(X) >>> A.toarray() array([[1., 0., 1.], [0., 1., 1.], [1., 0., 1.]])
```

**predict**(X)

Predict the class labels for the provided data.

**Parameters**

**X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

**Returns**

y [ndarray of shape (n_queries,) or (n_queries, n_outputs)] Class labels for each data sample.

**predict_proba**(X)

Return probability estimates for the test data X.

**Parameters**

**X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

**Returns**

p [ndarray of shape (n_queries, n_classes), or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.
score \((X, y, \text{sample_weight}=\text{None})\)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- \(X\) [array-like of shape (n_samples, n_features)] Test samples.
- \(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).
- \text{sample_weight} [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- \text{score} [float] Mean accuracy of self.predict \((X)\) wrt. \(y\).

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params [dict] Estimator parameters.

Returns

Examples using sklearn.neighbors.KNeighborsClassifier

- Classifier comparison
- Plot the decision boundaries of a VotingClassifier
- Nearest Neighbors Classification
- Caching nearest neighbors
- Comparing Nearest Neighbors with and without Neighborhood Components Analysis
- Dimensionality Reduction with Neighborhood Components Analysis
- Digits Classification Exercise
- Classification of text documents using sparse features

7.30.6 sklearn.neighbors.KNeighborsRegressor

class sklearn.neighbors.KNeighborsRegressor(**kwargs)

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the User Guide.

New in version 0.9.

Parameters

- \text{n_neighbors} [int, default=5] Number of neighbors to use by default for knn nearest neighbors.
weights [‘uniform’, ‘distance’] or callable, default=’uniform’] weight function used in prediction. Possible values:

- ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
- ‘distance’ : weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=’auto’] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric [str or callable, default=’minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. Doesn’t affect fit method.

Attributes

effective_metric_ [str or callable] The distance metric to use. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

`fit(X, y)`

Fit the k-nearest neighbors regressor from the training dataset.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed'] Training data.
- **y** [[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)] Target values.

**Returns**

- **self** [KNeighborsRegressor] The fitted k-nearest neighbors regressor.
get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

kneighbors (X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters

X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-
computed’, default=None] The query point or points. If not provided, neighbors of each
indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors [int, default=None] Number of neighbors required for each sample. The de-
default is the value passed to the constructor.

return_distance [bool, default=True] Whether or not to return the distances.

Returns

neigh_dist [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to
points, only present if return_distance=True

neigh_ind [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the
population matrix.

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set
and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third
element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])...
```

kneighbors_graph (X=None, n_neighbors=None, mode=‘connectivity’)
Computes the (weighted) graph of k-Neighbors for points in X

Parameters
X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

n_neighbors [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

mode [‘connectivity’, ‘distance’, default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

See also:

NearestNeighbors.radius_neighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

predict (X)

Predict the target for the provided data

Parameters

X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

Returns

y [ndarray of shape (n_queries,) or (n_queries, n_outputs), dtype=int] Target values.

score (X, y, sample_weight=None)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \((y_{true} - y_{pred})**2\).sum()\) and \( v \) is the total sum of squares \((y_{true} - y_{true}.mean())**2\).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a \( R^2 \) score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.neighbors.KNeighborsRegressor

- Face completion with a multi-output estimators
- Imputing missing values with variants of IterativeImputer
- Nearest Neighbors regression

7.30.7 sklearn.neighbors.KNeighborsTransformer

class sklearn.neighbors.KNeighborsTransformer(**kwargs)

Transform X into a (weighted) graph of k nearest neighbors

The transformed data is a sparse graph as returned by kneighbors_graph.

Read more in the User Guide.

New in version 0.22.

Parameters

mode [[‘distance’, ‘connectivity’], default=’distance’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.
n_neighbors [int, default=5] Number of neighbors for each sample in the transformed sparse graph. For compatibility reasons, as each sample is considered as its own neighbor, one extra neighbor will be computed when mode == ‘distance’. In this case, the sparse graph contains (n_neighbors + 1) neighbors.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=’auto’] Algorithm used to compute the nearest neighbors:
  • ‘ball_tree’ will use BallTree
  • ‘kd_tree’ will use KDTree
  • ‘brute’ will use a brute-force search.
  • ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric [str or callable, default=’minkowski’] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=1] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

Attributes

effective_metric_ [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.
Examples

```python
>>> from sklearn.manifold import Isomap
>>> from sklearn.neighbors import KNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline

>>> estimator = make_pipeline(
...    KNeighborsTransformer(n_neighbors=5, mode='distance'),
...    Isomap(neighbors_algorithm='precomputed'))
```

**fit (X, y=None)**

Fit the k-nearest neighbors transformer from the training dataset.

**Parameters**

- *X* [(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed')] Training data.

**Returns**

- *self* [KNeighborsTransformer] The fitted k-nearest neighbors transformer.

**fit_transform (X, y=None)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- *X* [array-like of shape (n_samples, n_features)] Training set.
  - *y* [ignored]

**Returns**

- *Xt* [sparse matrix of shape (n_samples, n_samples)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- *deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params**  [dict] Parameter names mapped to their values.

**kneighbors**  
(\(X=\text{None}, n\_neighbors=\text{None}, return\_distance=\text{True}\))

Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters

**X**  [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n_neighbors**  [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.

**return_distance**  [bool, default=True] Whether or not to return the distances.

Returns

**neigh_dist**  [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True

**neigh_ind**  [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to \([1,1,1]\)

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns \([[0.5]]\), and \([[2]]\), which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1], [2]])
```

**kneighbors_graph**  
(\(X=\text{None}, n\_neighbors=\text{None}, mode='\text{connectivity}'\))

Computes the (weighted) graph of k-Neighbors for points in X

Parameters

**X**  [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).
n_neighbors [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

mode [{‘connectivity’, ‘distance’}, default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns
A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

See also:
NearestNeighbors.radius_neighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]]
```

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Computes the (weighted) graph of Neighbors for points in X

Parameters

X [array-like of shape (n_samples_transform, n_features)] Sample data.

Returns

Xt [sparse matrix of shape (n_samples_transform, n_samples_fit)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.
Examples using `sklearn.neighbors.KNeighborsTransformer`  

- Approximate nearest neighbors in TSNE

### 7.30.8 `sklearn.neighbors.LocalOutlierFactor`

**class sklearn.neighbors.LocalOutlierFactor(**kwargs\)**

Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by k-nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

New in version 0.19.

**Parameters**

- **n_neighbors** [int, default=20] Number of neighbors to use by default for `kneighbors` queries. If `n_neighbors` is larger than the number of samples provided, all samples will be used.

- **algorithm** [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use `BallTree`
  - ‘kd_tree’ will use `KDTree`
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

  Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, default=30] Leaf size passed to `BallTree` or `KDTree`. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **metric** [str or callable, default=’minkowski’] metric used for the distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

  If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors.

  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

  Valid values for metric are:
See the documentation for scipy.spatial.distance for details on these metrics: https://docs.scipy.org/doc/scipy/reference/spatial.distance.html

p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

contamination ['auto' or float, default='auto'] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the scores of the samples.

- if ‘auto’, the threshold is determined as in the original paper,
- if a float, the contamination should be in the range [0, 0.5].

Changed in version 0.22: The default value of contamination changed from 0.1 to 'auto'.

novelty [bool, default=False] By default, LocalOutlierFactor is only meant to be used for outlier detection (novelty=False). Set novelty to True if you want to use LocalOutlierFactor for novelty detection. In this case be aware that that you should only use predict, decision_function and score_samples on new unseen data and not on the training set.

New in version 0.20.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

negative_outlier_factor_ [ndarray of shape (n_samples,)] The opposite LOF of the training samples. The higher, the more normal. Inliers tend to have a LOF score close to 1 (negative_outlier_factor_ close to -1), while outliers tend to have a larger LOF score.

The local outlier factor (LOF) of a sample captures its supposed ‘degree of abnormality’. It is the average of the ratio of the local reachability density of a sample and those of its k-nearest neighbors.

n_neighbors_ [int] The actual number of neighbors used for kneighbors queries.

offset_ [float] Offset used to obtain binary labels from the raw scores. Observations having a negative_outlier_factor smaller than offset_ are detected as abnormal. The offset is set to -1.5 (inliers score around -1), except when a contamination parameter different than “auto” is provided. In that case, the offset is defined in such a way we obtain the expected number of outliers in training.

New in version 0.20.

effective_metric_ [str] The effective metric used for the distance computation.

effective_metric_params_ [dict] The effective additional keyword arguments for the metric function.

n_samples_fit_ [int] It is the number of samples in the fitted data.
References

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.neighbors import LocalOutlierFactor
>>> X = [[-1.1], [0.2], [101.1], [0.3]]
>>> clf = LocalOutlierFactor(n_neighbors=2)
>>> clf.fit_predict(X)
array([ 1, 1, -1, 1])
>>> clf.negative_outlier_factor_
array([-0.9821..., -1.0370..., -73.3697..., -0.9821...])
```

Methods

- `fit(X[, y])` Fit the local outlier factor detector from the training dataset.
- `get_params([deep])` Get parameters for this estimator.
- `kneighbors([X, n_neighbors, return_distance])` Finds the K-neighbors of a point.
- `kneighbors_graph([X, n_neighbors, mode])` Computes the (weighted) graph of k-Neighbors for points in X
- `set_params(**params)` Set the parameters of this estimator.

**property decision_function**

Shifted opposite of the Local Outlier Factor of X.

Bigger is better, i.e. large values correspond to inliers.

Only available for novelty detection (when novelty is set to True). The shift offset allows a zero threshold for being an outlier. The argument X is supposed to contain new data: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point.

Parameters

- `X` [array-like of shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

Returns

- `shifted_opposite_lof_scores` [ndarray of shape (n_samples,)] The shifted opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

**fit(X, y=None)**

Fit the local outlier factor detector from the training dataset.

Parameters

- `X` [{array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed'] Training data.
- `y` [Ignored] Not used, present for API consistency by convention.

Returns
**property fit_predict**
Fits the model to the training set X and returns the labels.

Only available for novelty detection (when novelty is set to True). Label is 1 for an inlier and -1 for an outlier according to the LOF score and the contamination parameter.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.
- **y** [Ignored] Not used, present for API consistency by convention.

**Returns**

- **is_inlier** [ndarray of shape (n_samples,)] Returns -1 for anomalies/outliers and 1 for inliers.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**kneighbors**(X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors** [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.
- **return_distance** [bool, default=True] Whether or not to return the distances.

**Returns**

- **neigh_dist** [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True
- **neigh_ind** [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.
Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])
```

`kneighbors_graph` ($X$=None, $n_neighbors$=None, $mode$='connectivity')

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

- **n_neighbors** [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

- **mode** ['connectivity', 'distance'], default='connectivity'] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

**See also:**

`NearestNeighbors.radius_neighbors_graph`
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

**property predict**

Predict the labels (1 inlier, -1 outlier) of X according to LOF.

*Only available for novelty detection (when novelty is set to True).* This method allows to generalize prediction to *new observations* (not in the training set).

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

**Returns**

- **is_inlier** [ndarray of shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

**property score_samples**

Opposite of the Local Outlier Factor of X.

It is the opposite as bigger is better, i.e. large values correspond to inliers.

*Only available for novelty detection (when novelty is set to True).* The argument X is supposed to contain *new data*: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point. The score_samples on training data is available by considering the the `negative_outlier_factor_` attribute.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

**Returns**

- **opposite_lof_scores** [ndarray of shape (n_samples,)] The opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.
Examples using `sklearn.neighbors.LocalOutlierFactor`

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Outlier detection with Local Outlier Factor (LOF)
- Novelty detection with Local Outlier Factor (LOF)

7.30.9 `sklearn.neighbors.RadiusNeighborsClassifier`

class `sklearn.neighbors.RadiusNeighborsClassifier(**kwargs)`
Classifier implementing a vote among neighbors within a given radius

Read more in the User Guide.

Parameters

- **radius** [float, default=1.0] Range of parameter space to use by default for `radius_neighbors` queries.
- **weights** [{'uniform', 'distance'} or callable, default='uniform'] weight function used in prediction. Possible values:
  - ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’: weight points by the inverse of their distance, in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  - [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

- **algorithm** [{'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto'] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **p** [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

- **metric** [str or callable, default='minkowski'] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

- **outlier_label** [{manual label, ‘most_frequent’}, default=None] label for outlier samples (samples with no neighbors in given radius).
• manual label: str or int label (should be the same type as y) or list of manual labels if multi-output is used.
• ‘most_frequent’ : assign the most frequent label of y to outliers.
• None : when any outlier is detected, ValueError will be raised.

metric_params  [dict, default=None] Additional keyword arguments for the metric function.

n_jobs  [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

classes_  [ndarray of shape (n_classes,)] Class labels known to the classifier.

effective_metric_  [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_  [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_  [int] Number of samples in the fitted data.

outlier_label_  [int or array-like of shape (n_class,)] Label which is given for outlier samples (samples with no neighbors on given radius).

outputs_2d_  [bool] False when y’s shape is (n_samples, ) or (n_samples, 1) during fit otherwise True.

**fit (X, y)**

Fit the radius neighbors classifier from the training dataset.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples) if metric=’precomputed’) Training data.
- **y** ([array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)) Target values.

**Returns**

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- parameters [dict] Parameter names mapped to their values.

**predict (X)**

Predict the class labels for the provided data.

**Parameters**

- **X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

**Returns**

- **y** [ndarray of shape (n_queries,) or (n_queries, n_outputs)] Class labels for each data sample.
predict_proba ($X$)
Return probability estimates for the test data $X$.

Parameters

$X$ [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’) ] Test samples.

Returns

$p$ [ndarray of shape (n_queries, n_classes), or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

radius_neighbors ($X=None$, radius=None, return_distance=True, sort_results=False)
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

$X$ [array-like of (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.

return_distance [bool, default=True] Whether or not to return the distances.

sort_results [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.

Returns

$\text{neigh\_dist}$ [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

$\text{neigh\_ind}$ [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.
Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to \([1, 1, 1]\):

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** (*X=None, radius=None, mode='connectivity', sort_results=False*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.
- **mode** [‘connectivity’, ‘distance’], default='connectivity] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.
- **sort_results** [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode=’distance’.

**Returns**

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

**See also:**

**kneighbors_graph**
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
dtype=...:
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

`score(X, y, sample_weight=None)`

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for `X`.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

`set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [estimator instance] Estimator instance.

### 7.30.10 sklearn.neighbors RadiusNeighborsRegressor

**class sklearn.neighbors.RadiusNeighborsRegressor(**kwargs)**

Regression based on neighbors within a fixed radius.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the `User Guide`.

New in version 0.9.

Parameters

- **radius** [float, default=1.0] Range of parameter space to use by default for `radius_neighbors` queries.
weights [[‘uniform’, ‘distance’] or callable, default=’uniform’] weight function used in prediction. Possible values:

- ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
- ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=’auto’] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric [str or callable, default=’minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

effective_metric_ [str or callable] The distance metric to use. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

RadiusNeighborsClassifier

Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

Methods

```python
fit(X, y) Fit the radius neighbors regressor from the training dataset.

get_params([deep]) Get parameters for this estimator.

predict(X) Predict the target for the provided data

radius_neighbors([[X, radius, ...]]) Finds the neighbors within a given radius of a point or points.

radius_neighbors_graph([X, radius, mode, ...]) Computes the (weighted) graph of Neighbors for points in X

score(X, y[, sample_weight]) Return the coefficient of determination \( R^2 \) of the prediction.

set_params(**params) Set the parameters of this estimator.
```

fit (X, y)
Fit the radius neighbors regressor from the training dataset.

Parameters

- `X` [[array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples)
  if metric='precomputed'] Training data.
- `y` [[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)] Target values.

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict the target for the provided data

Parameters

X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-
computed’] Test samples.

Returns

y [ndarray of shape (n_queries,) or (n_queries, n_outputs), dtype=double] Target values.

radius_neighbors (X=None, radius=None, return_distance=True, sort_results=False)
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around
the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

X [array-like of (n_samples, n_features), default=None] The query point or points. If not
provided, neighbors of each indexed point are returned. In this case, the query point is not
considered its own neighbor.

radius [float, default=None] Limiting distance of neighbors to return. The default is the
value passed to the constructor.

return_distance [bool, default=True] Whether or not to return the distances.

sort_results [bool, default=False] If True, the distances and indices will be sorted by in-
creasing distances before being returned. If False, the results may not be sorted. If
return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.

Returns

neigh_dist [ndarray of shape (n_samples,) of arrays] Array representing the distances to
each point, only present if return_distance=True. The distance values are com-
puted according to the metric constructor parameter.

neigh_ind [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the ap-
proximate nearest points from the population matrix that lie within a ball of size radius
around the query points.
Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

`radius_neighbors_graph` *(X=None, radius=None, mode='connectivity', sort_results=False)*

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

- **mode** ['connectivity', 'distance'], default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

- **sort_results** [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode='distance'.

**Returns**

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

**See also:**

`kneighbors_graph`
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())**2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict (X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.
7.30.11 sklearn.neighbors.RadiusNeighborsTransformer

class sklearn.neighbors.RadiusNeighborsTransformer(**kwargs)

Transform X into a (weighted) graph of neighbors nearer than a radius

The transformed data is a sparse graph as returned by radius_neighbors_graph.

Read more in the User Guide.

New in version 0.22.

Parameters

mode [‘distance’, ‘connectivity’], default=’distance’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

radius [float, default=1.] Radius of neighborhood in the transformed sparse graph.

algorithm [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’] Algorithm used to compute the nearest neighbors:
• ‘ball_tree’ will use BallTree
• ‘kd_tree’ will use KDTree
• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric [str or callable, default=’minkowski’] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.
n_jobs [int, default=1] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

Attributes

effective_metric_ [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

Examples

```python
>>> from sklearn.cluster import DBSCAN
>>> from sklearn.neighbors import RadiusNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline

>>> estimator = make_pipeline(...
...    RadiusNeighborsTransformer(radius=42.0, mode='distance'),
...    DBSCAN(min_samples=30, metric='precomputed'))
```

Methods

```markdown
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fit(X[, y])</td>
<td>Fit the radius neighbors transformer from the training dataset.</td>
</tr>
<tr>

<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td>transform(X)</td>
<td>Computes the (weighted) graph of Neighbors for points in X</td>
</tr>
</tbody>
</table>
```

fit (X, y=None)
Fit the radius neighbors transformer from the training dataset.

Parameters

- X [{array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed'] Training data.

Returns

fit_transform (X, y=None)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [array-like of shape (n_samples, n_features)] Training set.
y [ignored]

Returns
Xt [sparse matrix of shape (n_samples, n_samples)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

radius_neighbors (X=None, radius=None, return_distance=True, sort_results=False)
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

X [array-like of (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.

return_distance [bool, default=True] Whether or not to return the distances.

sort_results [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.

Returns

neigh_dist [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

neigh_ind [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.
Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to \([1, 1, 1]\):

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

`radius_neighbors_graph` (`X=None, radius=None, mode='connectivity', sort_results=False`)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Parameters

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

- **mode** [{‘connectivity’, ‘distance’}, default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

- **sort_results** [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode=’distance’.

Returns

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

See also:

- `kneighbors_graph`
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**set_params(**params)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform**(X)
Computes the (weighted) graph of Neighbors for points in X

**Parameters**

X [array-like of shape (n_samples_transform, n_features)] Sample data

**Returns**

Xt [sparse matrix of shape (n_samples_transform, n_samples_fit)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

### 7.30.12 sklearn.neighbors.NearestCentroid

**class** sklearn.neighbors.NearestCentroid(**kwargs)**
Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the User Guide.

**Parameters**

metric [str or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `metrics.pairwise.pairwise_distances` for its metric parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to the metric) of all samples that belong to that particular class are minimized. If the “manhattan” metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.
Changed in version 0.19: metric='precomputed' was deprecated and now raises an error

**shrink_threshold** [float, default=None] Threshold for shrinking centroids to remove features.

**Attributes**

**centroids_** [array-like of shape (n_classes, n_features)] Centroid of each class.

**classes_** [array of shape (n_classes,)] The unique classes labels.

**See also:**

**KNeighborsClassifier** Nearest neighbors classifier.

**Notes**

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.

**References**

**Examples**

```python
>>> from sklearn.neighbors import NearestCentroid
>>> import numpy as np

>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = NearestCentroid()
>>> clf.fit(X, y)
NearestCentroid()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

**Methods**

- **fit(X, y)**
  
  Fit the NearestCentroid model according to the given training data.

- **get_params([deep])**
  
  Get parameters for this estimator.

- **predict(X)**
  
  Perform classification on an array of test vectors X.

- **score(X, y[, sample_weight])**
  
  Return the mean accuracy on the given test data and labels.

- **set_params(**params)**
  
  Set the parameters of this estimator.

**Methods**

- **fit(X, y)**
  
  Fit the NearestCentroid model according to the given training data.

  **Parameters**

  - **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training vector, where
n_samples is the number of samples and n_features is the number of features. Note that centroid shrinking cannot be used with sparse matrices.

y [array-like of shape (n_samples,)] Target values (integers)

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)]

Notes

If the metric constructor parameter is “precomputed”, X is assumed to be the distance matrix between the data to be predicted and self.centroids_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

Examples using sklearn.neighbors.NearestCentroid

• Nearest Centroid Classification
• Classification of text documents using sparse features

7.30.13 sklearn.neighbors.NearestNeighbors
class sklearn.neighbors.NearestNeighbors(**kwargs)
Unsupervised learner for implementing neighbor searches.

Read more in the User Guide.

New in version 0.9.

Parameters

n_neighbors [int, default=5] Number of neighbors to use by default for kneighbors queries.

radius [float, default=1.0] Range of parameter space to use by default for radius_neighbors queries.

algorithm [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’] Algorithm used to compute the nearest neighbors:
• ‘ball_tree’ will use BallTree
• ‘kd_tree’ will use KDTree
• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric [str or callable, default=’minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

effective_metric_ [str] Metric used to compute distances to neighbors.
**effective_metric_params**  [dict] Parameters for the metric used to compute distances to neighbors.

**n_samples_fit**  [int] Number of samples in the fitted data.

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and leaf_size.

Examples

```python
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]

>>> neigh = NearestNeighbors(n_neighbors=2, radius=0.4)
>>> neigh.fit(samples)
NearestNeighbors(...)

>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
array([[2, 0]])

>>> nbrs = neigh.radius_neighbors(...)

>>> np.asarray(nbrs[0][0])
array(2)
```

Methods

- `fit(X[, y])`  
  Fit the nearest neighbors estimator from the training dataset.
- `get_params([deep])`  
  Get parameters for this estimator.
- `kneighbors([X, n_neighbors, return_distance])`  
  Finds the K-neighbors of a point.
- `kneighbors_graph([X, n_neighbors, mode])`  
  Computes the (weighted) graph of k-Neighbors for points in X
- `radius_neighbors([X, radius, ...])`  
  Finds the neighbors within a given radius of a point or points.

**fit** *(X, y=None)*

Fit the nearest neighbors estimator from the training dataset.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples, n_samples)*<br>  if metric='precomputed' Training data.
- **y** *(ignored)* Not used, present for API consistency by convention.

**Returns**

- **self** *(NearestNeighbors)* The fitted nearest neighbors estimator.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** *(bool, default=True)* If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** *(dict)* Parameter names mapped to their values.

**kneighbors** *(X=None, n_neighbors=None, return_distance=True)*

Finds the K-neighbors of a point.

**Parameters**

- **X** *(array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed', default=None)* The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors** *(int, default=None)* Number of neighbors required for each sample. The default is the value passed to the constructor.
- **return_distance** *(bool, default=True)* Whether or not to return the distances.

**Returns**

- **neigh_dist** *(ndarray of shape (n_queries, n_neighbors)]* Array representing the lengths to points, only present if return_distance=True
- **neigh_ind** *(ndarray of shape (n_queries, n_neighbors)]* Indices of the nearest points in the population matrix.
Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])
```

**kneighbors_graph** *(X=None, n_neighbors=None, mode='connectivity')*

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

- **n_neighbors** [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

- **mode** [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

- **See also:**

  - **NearestNeighbors.radius_neighbors_graph**
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
```

```python
>>> A.toarray()
anndarray([[1., 0., 1.], 
          [0., 1., 1.], 
          [1., 0., 1.]])
```

radius_neighbors(X=None, radius=None, return_distance=True, sort_results=False)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

- **X** [array-like of (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.
- **return_distance** [bool, default=True] Whether or not to return the distances.
- **sort_results** [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.

Returns

- **neigh_dist** [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.
- **neigh_ind** [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.
Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

`radius_neighbors_graph` (X=None, radius=None, mode='connectivity', sort_results=False)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

- **mode** [‘connectivity’, ‘distance’], default=’connectivity’ Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

- **sort_results** [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode=’distance’.

  New in version 0.22.

**Returns**

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

**See also:**

`kneighbors_graph`
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**set_params(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### 7.30.14 sklearn.neighbors.NeighborhoodComponentsAnalysis

**class sklearn.neighbors.NeighborhoodComponentsAnalysis(**kwargs)**

Neighborhood Component Analysis (NCA) is a machine learning algorithm for metric learning. It learns a linear transformation in a supervised fashion to improve the classification accuracy of a stochastic nearest neighbors rule in the transformed space.

**Parameters**

- **n_components** [int, default=None] Preferred dimensionality of the projected space. If None it will be set to `n_features`.
- **auto** Depending on `n_components`, the most reasonable initialization will be chosen. If `n_components <= n_classes` we use ‘lda’, as it uses labels information. If not, but `n_components < min(n_features, n_samples)`, we use ‘pca’, as it projects data in meaningful directions (those of higher variance). Otherwise, we just use ‘identity’.
- **pca** `n_components` principal components of the inputs passed to fit will be used to initialize the transformation. (See PCA)
- **lda** `min(n_components, n_classes)` most discriminative components of the inputs passed to fit will be used to initialize the transformation. (If
n_components > n_classes, the rest of the components will be zero.) (See LinearDiscriminantAnalysis)

`identity` If n_components is strictly smaller than the dimensionality of the inputs passed to fit, the identity matrix will be truncated to the first n_components rows.

`random` The initial transformation will be a random array of shape (n_components, n_features). Each value is sampled from the standard normal distribution.

**numpy array** n_features_b must match the dimensionality of the inputs passed to fit and n_features_a must be less than or equal to that. If n_components is not None, n_features_a must match it.

**warm_start** [bool, default=False] If True and fit has been called before, the solution of the previous call to fit is used as the initial linear transformation (n_components and init will be ignored).

**max_iter** [int, default=50] Maximum number of iterations in the optimization.

**tol** [float, default=1e-5] Convergence tolerance for the optimization.

**callback** [callable, default=None] If not None, this function is called after every iteration of the optimizer, taking as arguments the current solution (flattened transformation matrix) and the number of iterations. This might be useful in case one wants to examine or store the transformation found after each iteration.

**verbose** [int, default=0] If 0, no progress messages will be printed. If 1, progress messages will be printed to stdout. If > 1, progress messages will be printed and the disp parameter of scipy.optimize.minimize will be set to verbose - 2.

**random_state** [int or numpy.RandomState, default=None] A pseudo random number generator object or a seed for it if int. If init='random', random_state is used to initialize the random transformation. If init='pca', random_state is passed as an argument to PCA when initializing the transformation. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

**Attributes**

- `components_` [ndarray of shape (n_components, n_features)] The linear transformation learned during fitting.
- `n_iter_` [int] Counts the number of iterations performed by the optimizer.
- `random_state_` [numpy.RandomState] Pseudo random number generator object used during initialization.

**fit** *(X, y)*

Fit the model according to the given training data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training samples.
- **y** [array-like of shape (n_samples,)] The corresponding training labels.

**Returns**

- **self** [object] returns a trained NeighborhoodComponentsAnalysis model.

**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Returns**

**fit_params** [dict] Additional fit parameters.
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Applies the learned transformation to the given data.

Parameters

X [array-like of shape (n_samples, n_features)] Data samples.

Returns

X_embedded: ndarray of shape (n_samples, n_components) The data samples transformed.

Raises

NotFittedError If fit has not been called before.

neighbors.kneighbors_graph(X, n_neighbors, *) Computes the (weighted) graph of k-Neighbors for points in X
neighbors.radius_neighbors_graph(X, radius, *) Computes the (weighted) graph of Neighbors for points in X
7.30.15 sklearn.neighbors.kneighbors_graph

sklearn.neighbors.kneighbors_graph(X, n_neighbors, *, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)

Computes the (weighted) graph of k-Neighbors for points in X

Read more in the User Guide.

Parameters

X [array-like of shape (n_samples, n_features) or BallTree] Sample data, in the form of a numpy array or a precomputed BallTree.

n_neighbors [int] Number of neighbors for each sample.

mode [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

metric [str, default='minkowski'] The distance metric used to calculate the k-Neighbors for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the p param equal to 2.).

p [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] additional keyword arguments for the metric function.

include_self [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode=’connectivity’ and False for mode=’distance’.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

A [sparse matrix of shape (n_samples, n_samples)] Graph where A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

radius_neighbors_graph

Examples

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import kneighbors_graph
>>> A = kneighbors_graph(X, 2, mode='connectivity', include_self=True)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
Examples using `sklearn.neighbors.kneighbors_graph`

- Agglomerative clustering with and without structure
- Hierarchical clustering: structured vs unstructured ward
- Comparing different clustering algorithms on toy datasets

7.30.16 `sklearn.neighbors.radius_neighbors_graph`

`sklearn.neighbors.radius_neighbors_graph(X, radius, *, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)`

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Read more in the User Guide.

Parameters

- `X` [array-like of shape (n_samples, n_features) or BallTree] Sample data, in the form of a numpy array or a precomputed BallTree.
- `radius` [float] Radius of neighborhoods.
- `mode` ['connectivity', 'distance'], default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.
- `metric` [str, default='minkowski'] The distance metric used to calculate the neighbors within a given radius for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the param equal to 2.)
- `p` [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.
- `metric_params` [dict, default=None] additional keyword arguments for the metric function.
- `include_self` [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode='connectivity’ and False for mode='distance’.
- `n_jobs` [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

- `A` [sparse matrix of shape (n_samples, n_samples)] Graph where A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import radius_neighbors_graph
>>> A = radius_neighbors_graph(X, 1.5, mode='connectivity',
                            include_self=True)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

7.31 sklearn.neural_network: Neural network models

The `sklearn.neural_network` module includes models based on neural networks.

**User guide:** See the **Neural network models (supervised)** and **Neural network models (unsupervised)** sections for further details.

### 7.31.1 sklearn.neural_network.BernoulliRBM

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2].

The time complexity of this implementation is $O(d \cdot 2)$ assuming $d \sim n\_features \sim n\_components$.

Read more in the **User Guide**.

**Parameters**

- `n_components` [int, default=256] Number of binary hidden units.
- `learning_rate` [float, default=0.1] The learning rate for weight updates. It is highly recommended to tune this hyper-parameter. Reasonable values are in the $10^{[0.,-3.]}$ range.
- `batch_size` [int, default=10] Number of examples per minibatch.
- `n_iter` [int, default=10] Number of iterations/sweeps over the training dataset to perform during training.
- `verbose` [int, default=0] The verbosity level. The default, zero, means silent mode.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for:
  - Gibbs sampling from visible and hidden layers.
  - Initializing components, sampling from layers during fit.
  - Corrupting the data when scoring samples.

Pass an int for reproducible results across multiple function calls. See **Glossary**.
Attributes

- **intercept_hidden_** [array-like of shape (n_components,)] Biases of the hidden units.
- **intercept_visible_** [array-like of shape (n_features,)] Biases of the visible units.
- **components_** [array-like of shape (n_components, n_features)] Weight matrix, where n_features is the number of visible units and n_components is the number of hidden units.
- **h_samples_** [array-like of shape (batch_size, n_components)] Hidden Activation sampled from the model distribution, where batch_size is the number of examples per minibatch and n_components is the number of hidden units.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
BernoulliRBM(n_components=2)
```

Methods

```python
fit(X[, y]) Fit the model to the data X.

fit_transform(X[, y]) Fit to data, then transform it.
gibbs(v) Perform one Gibbs sampling step.
```

```python
partial_fit(X[, y]) Fit the model to the data X which should contain a partial segment of the data.
```

```python
score_samples(X) Compute the pseudo-likelihood of X.
```

```python
transform(X) Compute the hidden layer activation probabilities, P(h=1|v=X).
```

```python
fit (X, y=None) Fit the model to the data X.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data.

Returns

- **self** [BernoulliRBM] The fitted model.

fit_transform (X, y=None, **fit_params)```
Fit to data, then transform it.

Fits transformer to $X$ and $y$ with optional parameters `fit_params` and returns a transformed version of $X$.

**Parameters**

- $X$ [array-like of shape (n_samples, n_features)] Input samples.
- $y$ [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

- $X_{\text{new}}$ [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

**gibbs**(v)

Perform one Gibbs sampling step.

**Parameters**

- v [ndarray of shape (n_samples, n_features)] Values of the visible layer to start from.

**Returns**

- v_new [ndarray of shape (n_samples, n_features)] Values of the visible layer after one Gibbs step.

**partial_fit**(X, y=None)

Fit the model to the data $X$ which should contain a partial segment of the data.

**Parameters**

- X [ndarray of shape (n_samples, n_features)] Training data.

**Returns**

- self [BernoulliRBM] The fitted model.

**score_samples**(X)

Compute the pseudo-likelihood of $X$.

**Parameters**

- X [{array-like, sparse matrix} of shape (n_samples, n_features)] Values of the visible layer. Must be all-boolean (not checked).

**Returns**

- pseudo likelihood [ndarray of shape (n_samples,)] Value of the pseudo-likelihood (proxy for likelihood).
Notes

This method is not deterministic: it computes a quantity called the free energy on X, then on a randomly corrupted version of X, and returns the log of the logistic function of the difference.

```
set_params(**params)
```

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

```
transform(X)
```

Compute the hidden layer activation probabilities, P(h=1|v=X).

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features)] The data to be transformed.

Returns

h [ndarray of shape (n_samples, n_components)] Latent representations of the data.

Examples using `sklearn.neural_network.BernoulliRBM`

- Restricted Boltzmann Machine features for digit classification

7.31.2 `sklearn.neural_network.MLPClassifier`

class `sklearn.neural_network.MLPClassifier(**kwargs)`

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

Parameters

- `hidden_layer_sizes` [tuple, length = n_layers - 2, default=(100,)] The ith element represents the number of neurons in the ith hidden layer.
  - ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
  - ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
  - ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
  - ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)
- `solver` [{‘lbfgs’, ‘sgd’, ‘adam’}, default=’adam’] The solver for weight optimization.
  - ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
• ‘sgd’ refers to stochastic gradient descent.
• ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch_size** [int, default=‘auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, batch_size=min(200, n_samples)

**learning_rate** [{‘constant’, ‘invscaling’, ‘adaptive’}, default=’constant’] Learning rate schedule for weight updates.
• ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
• ‘invscaling’ gradually decreases the learning rate at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)
• ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver=’sgd’.

**learning_rate_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver=’sgd’ or ‘adam’.

**power_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver=’sgd’.

**max_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, default=True] Whether to shuffle samples in each iteration. Only used when solver=’sgd’ or ‘adam’.

**random_state** [int, RandomState instance, default=None] Determines random number generation for weights and bias initialization, train-test split if early stopping is used, and batch sampling when solver=’sgd’ or ‘adam’. Pass an int for reproducible results across multiple function calls. See Glossary.

**tol** [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

**verbose** [bool, default=False] Whether to print progress messages to stdout.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

**momentum** [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver=’sgd’.
nesterovs_momentum [bool, default=True] Whether to use Nesterov’s momentum. Only used when solver=’sgd’ and momentum > 0.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. The split is stratified, except in a multilabel setting. Only effective when solver=’sgd’ or ‘adam’

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver=’adam’

beta_2 [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver=’adam’

epsilon [float, default=1e-8] Value for numerical stability in adam. Only used when solver=’adam’

n_iter_no_change [int, default=10] Maximum number of epochs to not meet tol improvement. Only effective when solver=’sgd’ or ‘adam’

New in version 0.20.

max_fun [int, default=15000] Only used when solver=’lbfgs’. Maximum number of loss function calls. The solver iterates until convergence (determined by ‘tol’), number of iterations reaches max_iter, or this number of loss function calls. Note that number of loss function calls will be greater than or equal to the number of iterations for the MLPClassifier.

New in version 0.22.

Attributes

classes_ [ndarray or list of ndarray of shape (n_classes,)] Class labels for each output.

loss_ [float] The current loss computed with the loss function.

best_loss_ [float] The minimum loss reached by the solver throughout fitting.

loss_curve_ [list of shape (n_iter_,)] The ith element in the list represents the loss at the ith iteration.

t_ [int] The number of training samples seen by the solver during fitting.

coefs_ [list of shape (n_layers - 1,)] The ith element in the list represents the weight matrix corresponding to layer i.

intercepts_ [list of shape (n_layers - 1,)] The ith element in the list represents the bias vector corresponding to layer i + 1.

n_iter_ [int] The number of iterations the solver has ran.

n_layers_ [int] Number of layers.

n_outputs_ [int] Number of outputs.

out_activation_ [str] Name of the output activation function.
Notes

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to
the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent over-
fitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point
values.

Examples

```python
>>> from sklearn.neural_network import MLPClassifier
>>> from sklearn.datasets import make_classification
>>> from sklearn.model_selection import train_test_split

>>> X, y = make_classification(n_samples=100, random_state=1)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, stratify=y, ...
... random_state=1)
>>> clf = MLPClassifier(random_state=1, max_iter=300).fit(X_train, y_train)
>>> clf.predict_proba(X_test[:1])
array([[0.038..., 0.961...]])
>>> clf.predict(X_test[:5, :])
array([1, 0, 1, 0, 1])
>>> clf.score(X_test, y_test)
0.8...
```

Methods

- `fit(X, y)`  
  Fit the model to data matrix X and target(s) y.
- `get_params([deep])`  
  Get parameters for this estimator.
- `predict(X)`  
  Predict using the multi-layer perceptron classifier
- `predict_log_proba(X)`  
  Return the log of probability estimates.
- `predict_proba(X)`  
  Probability estimates.
- `score(X, y[, sample_weight])`  
  Return the mean accuracy on the given test data and labels.
- `set_params(**params)`  
  Set the parameters of this estimator.

```python
fit(X, y)
Fit the model to data matrix X and target(s) y.
```
Parameters

\( \text{X} \) [ndarray or sparse matrix of shape \( (n_{\text{samples}}, n_{\text{features}}) \)] The input data.

\( \text{y} \) [ndarray of shape \( (n_{\text{samples}},) \) or \( (n_{\text{samples}}, n_{\text{outputs}}) \)] The target values (class labels in classification, real numbers in regression).

Returns

self [returns a trained MLP model.]

get_params \( (\text{deep}=\text{True}) \)
Get parameters for this estimator.

Parameters

\( \text{deep} \) [bool, default=\text{True}] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property partial_fit
Update the model with a single iteration over the given data.

Parameters

\( \text{X} \) [[array-like, sparse matrix] of shape \( (n_{\text{samples}}, n_{\text{features}}) \)] The input data.

\( \text{y} \) [array-like of shape \( (n_{\text{samples}},) \)] The target values.

\( \text{classes} \) [array of shape \( (n_{\text{classes}},) \), default=None] Classes across all calls to partial_fit. Can be obtained via \( \text{np.unique(y\_all)} \), where \( y\_all \) is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that \( y \) doesn’t need to contain all labels in \( \text{classes} \).

Returns

self [returns a trained MLP model.]

predict \( (\text{X}) \)
Predict using the multi-layer perceptron classifier.

Parameters

\( \text{X} \) [[array-like, sparse matrix] of shape \( (n_{\text{samples}}, n_{\text{features}}) \)] The input data.

Returns

\( \text{y} \) [ndarray, shape \( (n_{\text{samples}},) \) or \( (n_{\text{samples}}, n_{\text{classes}}) \)] The predicted classes.

predict_log_proba \( (\text{X}) \)
Return the log of probability estimates.

Parameters

\( \text{X} \) [ndarray of shape \( (n_{\text{samples}}, n_{\text{features}}) \)] The input data.

Returns

\( \text{log\_y\_prob} \) [ndarray of shape \( (n_{\text{samples}}, n_{\text{classes}}) \)] The predicted log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_. Equivalent to \( \text{log}(\text{predict\_proba}(\text{X})) \)

predict_proba \( (\text{X}) \)
Probability estimates.
Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

Returns

y_prob  [ndarray of shape (n_samples, n_classes)] The predicted probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

score(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples.
y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

Examples using sklearn.neural_network.MLPClassifier

- Classifier comparison
- Visualization of MLP weights on MNIST
- Compare Stochastic learning strategies for MLPClassifier
- Varying regularization in Multi-layer Perceptron

7.31.3 sklearn.neural_network.MLPRegressor

class sklearn.neural_network.MLPRegressor(**kwargs)

Multi-layer Perceptron regressor.

This model optimizes the squared-loss using LBFGS or stochastic gradient descent.

New in version 0.18.

Parameters
**hidden_layer_sizes** [tuple, length = n_layers - 2, default=(100,)] The ith element represents the number of neurons in the ith hidden layer.

- ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
- ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
- ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
- ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)

**solver** [‘lbfgs’, ‘sgd’, ‘adam’, default=’adam’] The solver for weight optimization.
- ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
- ‘sgd’ refers to stochastic gradient descent.
- ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch_size** [int, default=’auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, batch_size=min(200, n_samples)

- ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
- ‘invscaling’ gradually decreases the learning rate learning_rate_ at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)
- ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver=’sgd’.

**learning_rate_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver=’sgd’ or ‘adam’.

**power_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver=’sgd’.

**max_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, default=True] Whether to shuffle samples in each iteration. Only used when solver=’sgd’ or ‘adam’.
random_state [int, RandomState instance, default=None] Determines random number generation for weights and bias initialization, train-test split if early stopping is used, and batch sampling when solver='sgd' or ‘adam’. Pass an int for reproducible results across multiple function calls. See *Glossary*.

tol [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

verbose [bool, default=False] Whether to print progress messages to stdout.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

momentum [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd’.

nesterovs_momentum [bool, default=True] Whether to use Nesterov’s momentum. Only used when solver='sgd’.

ever_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. Only effective when solver='sgd' or ‘adam’.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam’.

beta_2 [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam’.

epsilon [float, default=1e-8] Value for numerical stability in adam. Only used when solver='adam’.

n_iter_no_change [int, default=10] Maximum number of epochs to not meet tol improvement. Only effective when solver='sgd' or ‘adam’

New in version 0.20.

max_fun [int, default=15000] Only used when solver='lbfgs’. Maximum number of function calls. The solver iterates until convergence (determined by ‘tol’), number of iterations reaches max_iter, or this number of function calls. Note that number of function calls will be greater than or equal to the number of iterations for the MLPRegressor.

New in version 0.22.

Attributes

- **loss_** [float] The current loss computed with the loss function.

- **best_loss_** [float] The minimum loss reached by the solver throughout fitting.

- **loss_curve_** [list of shape (n_iter_,)] The ith element in the list represents the loss at the ith iteration.

- **t_** [int] The number of training samples seen by the solver during fitting.

- **coefs_** [list of shape (n_layers - 1,)] The ith element in the list represents the weight matrix corresponding to layer i.
intercepts_ [list of shape (n_layers - 1,)] The ith element in the list represents the bias vector corresponding to layer i + 1.

n_iter_ [int] The number of iterations the solver has ran.

n_layers_ [int] Number of layers.

n_outputs_ [int] Number of outputs.

out_activation_ [str] Name of the output activation function.

loss_curve_ [list of shape (n_iters,)] Loss value evaluated at the end of each training step.

t_ [int] Mathematically equals n_iters * X.shape[0], it means time_step and it is used by optimizer’s learning rate scheduler.

Notes

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

</tr>
<tr>
<td>set_params(**params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**fit (X, y)**

Fit the model to data matrix X and target(s) y.

**Parameters**

- **X** [ndarray or sparse matrix of shape (n_samples, n_features)] The input data.
- **y** [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [returns a trained MLP model.]

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**property partial_fit**

Update the model with a single iteration over the given data.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.
- **y** [ndarray of shape (n_samples,)] The target values.

**Returns**

- **self** [returns a trained MLP model.]

**predict (X)**

Predict using the multi-layer perceptron model.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.

**Returns**

- **y** [ndarray of shape (n_samples, n_outputs)] The predicted values.

**score (X, y, sample_weight=None)**

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{\text{residual sum of squares}}{\text{total sum of squares}} = (\frac{\sum(y_{true} - y_{pred})^2}{\sum(y_{true} - y_{true}.\text{mean()}^2}) ^ 2 \text{.sum()}}.$
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using sklearn.neural_network.MLPRegressor**

- Partial Dependence and Individual Conditional Expectation Plots
- Advanced Plotting With Partial Dependence

**7.32 sklearn.pipeline: Pipeline**

The sklearn.pipeline module implements utilities to build a composite estimator, as a chain of transforms and estimators.

**User guide:** See the Pipelines and composite estimators section for further details.

<table>
<thead>
<tr>
<th>pipeline.FeatureUnion(**kwags)</th>
<th>Concatenates results of multiple transformer objects.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipeline.Pipeline(**kwags)</td>
<td>Pipeline of transforms with a final estimator.</td>
</tr>
</tbody>
</table>

**7.32. sklearn.pipeline: Pipeline**
7.32.1 sklearn.pipeline.FeatureUnion

```python
class sklearn.pipeline.FeatureUnion(**kwargs)
```

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a ‘__’. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to ‘drop’.

Read more in the User Guide.

New in version 0.13.

**Parameters**

- **transformer_list** [list of (string, transformer) tuples] List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer. The transformer can be ‘drop’ for it to be ignored.
  
  Changed in version 0.22: Deprecated None as a transformer in favor of ‘drop’.

- **n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.
  
  Changed in version v0.20: n_jobs default changed from 1 to None

- **transformer_weights** [dict, default=None] Multiplicative weights for features per transformer. Keys are transformer names, values the weights. Raises ValueError if key not present in `transformer_list`.

- **verbose** [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Attributes**

- **n_features_in_**

See also:

`make_union` Convenience function for simplified feature union construction.

**Examples**

```python
>>> from sklearn.pipeline import FeatureUnion
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> union = FeatureUnion(["pca", PCA(n_components=1)],
...                        ["svd", TruncatedSVD(n_components=2)])
>>> X = [[0., 1., 3], [2., 2., 5]]
>>> union.fit_transform(X)
array([[ 1.5 ,  3.0...,  0.8...],
       [-1.5 ,  5.7..., -0.4...]])
```
Methods

</tr>
</tbody>
</table>

**fit** *(X, y=None, **fit_params]*)

Fit all transformers using X.

**Parameters**

- **X** [iterable or array-like, depending on transformers] Input data, used to fit transformers.
- **y** [array-like of shape (n_samples, n_outputs), default=None] Targets for supervised learning.

**Returns**

- **self** [FeatureUnion] This estimator

**fit_transform** *(X, y=None, **fit_params]*)

Fit all transformers, transform the data and concatenate results.

**Parameters**

- **X** [iterable or array-like, depending on transformers] Input data to be transformed.
- **y** [array-like of shape (n_samples, n_outputs), default=None] Targets for supervised learning.

**Returns**

- **X_t** [array-like or sparse matrix of shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

**get_feature_names()**

Get feature names from all transformers.

**Returns**

- **feature_names** [list of strings] Names of the features produced by transform.

**get_params**(deep=True)

Get parameters for this estimator.

Returns the parameters given in the constructor as well as the estimators contained within the transformer_list of the FeatureUnion.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.
set_params(**kwargs)
Set the parameters of this estimator.
Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in transformer_list.

Returns
self

transform(X)
Transform X separately by each transformer, concatenate results.

Parameters
X [iterable or array-like, depending on transformers] Input data to be transformed.

Returns
X_t [array-like or sparse matrix of shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

Examples using sklearn.pipeline.FeatureUnion

- Concatenating multiple feature extraction methods

7.32.2 sklearn.pipeline.Pipeline

class sklearn.pipeline.Pipeline(**kwargs)
Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be ‘transforms’, that is, they must implement fit and transform methods. The final estimator only needs to implement fit.
The transformers in the pipeline can be cached using memory argument.
The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a ‘__’, as in the example below. A step’s estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting it to ‘passthrough’ or None.

Read more in the User Guide.

New in version 0.5.

Parameters

steps [list] List of (name, transform) tuples (implementing fit/transform) that are chained, in the order in which they are chained, with the last object an estimator.

memory [str or object with the joblib.Memory interface, default=None] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute named_steps or steps to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

verbose [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

Attributes
named_steps [Bunch] Dictionary-like object, with the following attributes. Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

See also:

make_pipeline Convenience function for simplified pipeline construction.

Examples

```python
>>> from sklearn.svm import SVC
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_classification
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.pipeline import Pipeline

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, ...
...     random_state=0)
>>> pipe = Pipeline([('scaler', StandardScaler()), ('svc', SVC())])
>>> # The pipeline can be used as any other estimator
>>> # and avoids leaking the test set into the train set
>>> pipe.fit(X_train, y_train)
Pipeline(steps=[('scaler', StandardScaler()), ('svc', SVC())])
>>> pipe.score(X_test, y_test)
0.88
```

Methods

decision_function(X) Apply transforms, and decision_function of the final estimator

fit(X[, y]) Fit the model

fit_predict(X[, y]) Applies fit_predict of last step in pipeline after transforms.

fit_transform(X[, y]) Fit the model and transform with the final estimator

get_params([deep]) Get parameters for this estimator.

predict(X, **predict_params) Apply transforms to the data, and predict with the final estimator

predict_log_proba(X) Apply transforms, and predict_log_proba of the final estimator

predict_proba(X) Apply transforms, and predict_proba of the final estimator

score(X[, y, sample_weight]) Apply transforms, and score with the final estimator

score_samples(X) Apply transforms, and score_samples of the final estimator.

set_params(**kwargs) Set the parameters of this estimator.

decision_function(X) Apply transforms, and decision_function of the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns
y_score [array-like of shape (n_samples, n_classes)]

**fit** *(X, y=None, **fit_params)*
Fit the model
Fit all the transforms one after the other and transform the data, then fit the transformed data using the final estimator.

Parameters

X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter p for step s has key s__p.

Returns

self [Pipeline] This estimator

**fit_predict** *(X, y=None, **fit_params)*
Applies fit_predict of last step in pipeline after transforms.
Applies fit_transforms of a pipeline to the data, followed by the fit_predict method of the final estimator in the pipeline. Valid only if the final estimator implements fit_predict.

Parameters

X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter p for step s has key s__p.

Returns

y_pred [array-like]

**fit_transform** *(X, y=None, **fit_params)*
Fit the model and transform with the final estimator
Fits all the transforms one after the other and transforms the data, then uses fit_transform on transformed data with the final estimator.

Parameters

X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter p for step s has key s__p.

Returns

Xt [array-like of shape (n_samples, n_transformed_features)] Transformed samples

**get_params** *(deep=True)*
Get parameters for this estimator.
Returns the parameters given in the constructor as well as the estimators contained within the steps of the Pipeline.
Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property inverse_transform

Apply inverse transformations in reverse order

All estimators in the pipeline must support inverse_transform.

Parameters

Xt [array-like of shape (n_samples, n_transformed_features)] Data samples, where n_samples is the number of samples and n_features is the number of features. Must fulfill input requirements of last step of pipeline's inverse_transform method.

Returns

Xt [array-like of shape (n_samples, n_features)]

predict (X, **predict_params)

Apply transforms to the data, and predict with the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**predict_params [dict of string -> object] Parameters to the predict called at the end of all transformations in the pipeline. Note that while this may be used to return uncertainties from some models with return_std or return_cov, uncertainties that are generated by the transformations in the pipeline are not propagated to the final estimator.

Returns

y_pred [array-like]

predict_log_proba (X)

Apply transforms, and predict_log_proba of the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

y_score [array-like of shape (n_samples, n_classes)]

predict_proba (X)

Apply transforms, and predict_proba of the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

y_proba [array-like of shape (n_samples, n_classes)]

score (X, y=None, sample_weight=None)

Apply transforms, and score with the final estimator

Parameters
X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.

sample_weight [array-like, default=None] If not None, this argument is passed as sample_weight keyword argument to the score method of the final estimator.

Returns

close [float]

score_samples(X)
Apply transforms, and score_samples of the final estimator.

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

cy_score [ndarray of shape (n_samples,)]

set_params(**kwargs)
Set the parameters of this estimator.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in steps.

Returns

self

property transform
Apply transforms, and transform with the final estimator

This also works where final estimator is None: all prior transformations are applied.

Parameters

X [iterable] Data to transform. Must fulfill input requirements of first step of the pipeline.

Returns

Xt [array-like of shape (n_samples, n_transformed_features)]

Examples using sklearn.pipeline.Pipeline

- Sample pipeline for text feature extraction and evaluation

```
pipeline.make_pipeline(*steps[, memory, verbose])
```

Construct a Pipeline from the given estimators.

```
pipeline.make_union(*transformers[, n_jobs, ...])
```

Construct a FeatureUnion from the given transformers.
sklearn.pipeline.make_pipeline

Construct a Pipeline from the given estimators.

This is a shorthand for the Pipeline constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.

Parameters

*steps [list of estimators.]

memory [str or object with the joblib.Memory interface, default=None] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute named_steps or steps to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

verbose [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

Returns

p [Pipeline]

See also:

Pipeline Class for creating a pipeline of transforms with a final estimator.

Examples

```python
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler

Pipeline(steps=[('standardscaler', StandardScaler()), ('gaussiannb', GaussianNB(priors=None))])
```

Examples using sklearn.pipeline.make_pipeline

- Approximate nearest neighbors in TSNE

sklearn.pipeline.make_union

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

Parameters

*transformers [list of estimators]
**n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

**verbose** [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Returns**

f [FeatureUnion]

**See also:**

FeatureUnion Class for concatenating the results of multiple transformer objects.

**Examples**

```python
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union
>>> make_union(PCA(), TruncatedSVD())
FeatureUnion(transformer_list=[('pca', PCA()), ('truncatedsvd', TruncatedSVD())])
```

### 7.33 sklearn.preprocessing: Preprocessing and Normalization

The sklearn.preprocessing module includes scaling, centering, normalization, binarization methods.

**User guide:** See the Preprocessing data section for further details.

Table 287 – continued from previous page

| **preprocessing.StandardScaler(**kwargs)** | Standardize features by removing the mean and scaling to unit variance |

7.33.1 sklearn.preprocessing.Binarizer

class sklearn.preprocessing.Binarizer(**kwargs)

Binarize data (set feature values to 0 or 1) according to a threshold.

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the User Guide.

Parameters

- **threshold** [float, default=0.0] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

- **copy** [bool, default=True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

- binarize Equivalent function without the estimator API.

Notes

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

Examples

```python
>>> from sklearn.preprocessing import Binarizer
>>> X = [[ 1., -1., 2.],
...      [ 2., 0., 0.],
...      [ 0., 1., -1.]]
>>> transformer = Binarizer().fit(X)  # fit does nothing.
>>> transformer
Binarizer()
>>> transformer.transform(X)
array([[1., 0., 1.],
       [1., 0., 0.],
       [0., 1., 0.]])
```
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X[, y])</code></td>
<td>Do nothing and return the estimator unchanged.</td>
</tr>
<tr>
<td><code>fit_transform(X[, y])</code></td>

<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(X[, copy])</code></td>
<td>Binarize each element of X.</td>
</tr>
</tbody>
</table>

#### `fit(X, y=None)`

Do nothing and return the estimator unchanged.

This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

- **X**  
  [[array-like, sparse matrix] of shape (n_samples, n_features)] The data.
- **y**  
  [None] Ignored.

**Returns**

- **self**  
  [object] Fitted transformer.

#### `fit_transform(X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X**  
  [array-like of shape (n_samples, n_features)] Input samples.
- **y**  
  [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params**  
  [dict] Additional fit parameters.

**Returns**

- **X_new**  
  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

#### `get_params`(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep**  
  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**  
  [dict] Parameter names mapped to their values.

#### `set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params**  
  [dict] Estimator parameters.
Returns

self  [estimator instance] Estimator instance.

transform (X, copy=None)
  Binarize each element of X.

Parameters

X   [[array-like, sparse matrix] of shape (n_samples, n_features)] The data to binarize, element by element. scipy.sparse matrices should be in CSR format to avoid an unnecessary copy.

copy  [bool] Copy the input X or not.

Returns

X_tr  [[ndarray, sparse matrix] of shape (n_samples, n_features)] Transformed array.

7.33.2 sklearn.preprocessing.FunctionTransformer

class sklearn.preprocessing.FunctionTransformer (**kwargs)
  Constructs a transformer from an arbitrary callable.

  A FunctionTransformer forwards its X (and optionally y) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

  Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

  New in version 0.17.

  Read more in the User Guide.

Parameters

func  [callable, default=None] The callable to use for the transformation. This will be passed the same arguments as transform, with args and kwargs forwarded. If func is None, then func will be the identity function.

inverse_func  [callable, default=None] The callable to use for the inverse transformation. This will be passed the same arguments as inverse transform, with args and kwargs forwarded. If inverse_func is None, then inverse_func will be the identity function.

validate  [bool, default=False] Indicate that the input X array should be checked before calling func. The possibilities are:
  • If False, there is no input validation.
  • If True, then X will be converted to a 2-dimensional NumPy array or sparse matrix. If the conversion is not possible an exception is raised.

  Changed in version 0.22: The default of validate changed from True to False.

accept_sparse  [bool, default=False] Indicate that func accepts a sparse matrix as input. If validate is False, this has no effect. Otherwise, if accept_sparse is false, sparse matrix inputs will cause an exception to be raised.

check_inverse  [bool, default=True] Whether to check that or func followed by inverse_func leads to the original inputs. It can be used for a sanity check, raising a warning when the condition is not fulfilled.

  New in version 0.20.
**kw_args** [dict, default=None] Dictionary of additional keyword arguments to pass to func.

New in version 0.18.

**inv_kw_args** [dict, default=None] Dictionary of additional keyword arguments to pass to inverse_func.

New in version 0.18.

### Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import FunctionTransformer
>>> transformer = FunctionTransformer(np.log1p)
>>> X = np.array([[0, 1], [2, 3]])
>>> transformer.transform(X)
array([[0.        , 0.69314718],
       [1.09861229, 1.38629436]])
```

### Methods

</table>

**fit (X, y=None)**

Fit transformer by checking X.

If validate is True, X will be checked.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Input array.

Returns

- **self**

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters **fit_params** and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.
**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [dict] Parameter names mapped to their values.

**inverse_transform**(X)
Transform X using the inverse function.

**Parameters**
- **X** [array-like, shape (n_samples, n_features)] Input array.

**Returns**
- **X_out** [array-like, shape (n_samples, n_features)] Transformed input.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**
- **params** [dict] Estimator parameters.

**Returns**
- **self** [estimator instance] Estimator instance.

**transform**(X)
Transform X using the forward function.

**Parameters**
- **X** [array-like, shape (n_samples, n_features)] Input array.

**Returns**
- **X_out** [array-like, shape (n_samples, n_features)] Transformed input.

**Examples using sklearn.preprocessing.FunctionTransformer**

- **Poisson regression and non-normal loss**
- **Tweedie regression on insurance claims**
- **Column Transformer with Heterogeneous Data Sources**
class sklearn.preprocessing.KBinsDiscretizer(**kwargs)

Bin continuous data into intervals.

Read more in the User Guide.

New in version 0.20.

Parameters

- **n_bins** [int or array-like of shape (n_features,), default=5] The number of bins to produce. Raises ValueError if n_bins < 2.
- **encode** ['onehot', 'onehot-dense', 'ordinal'], default='onehot'] Method used to encode the transformed result.
  - **onehot** Encode the transformed result with one-hot encoding and return a sparse matrix. Ignored features are always stacked to the right.
  - **onehot-dense** Encode the transformed result with one-hot encoding and return a dense array. Ignored features are always stacked to the right.
  - **ordinal** Return the bin identifier encoded as an integer value.
- **strategy** ['uniform', 'quantile', 'kmeans'], default='quantile'] Strategy used to define the widths of the bins.
  - **uniform** All bins in each feature have identical widths.
  - **quantile** All bins in each feature have the same number of points.
  - **kmeans** Values in each bin have the same nearest center of a 1D k-means cluster.
- **dtype** [np.float32, np.float64], default=None] The desired data-type for the output. If None, output dtype is consistent with input dtype. Only np.float32 and np.float64 are supported.

New in version 0.24.

Attributes

- **n_bins_** [ndarray of shape (n_features,), dtype=np.int_] Number of bins per feature. Bins whose width are too small (i.e., <= 1e-8) are removed with a warning.
- **bin_edges_** [ndarray of ndarray of shape (n_features,)] The edges of each bin. Contain arrays of varying shapes (n_bins_, ) Ignored features will have empty arrays.

See also:

**Binarizer** Class used to bin values as 0 or 1 based on a parameter threshold.

Notes

In bin edges for feature i, the first and last values are used only for inverse_transform. During transform, bin edges are extended to:

```python
np.concatenate([-np.inf, bin_edges_[i][1:-1], np.inf])
```

You can combine KBinsDiscretizer with ColumnTransformer if you only want to preprocess part of the features.
KBinsDiscretizer might produce constant features (e.g., when `encode = 'onehot'` and certain bins do not contain any data). These features can be removed with feature selection algorithms (e.g., `VarianceThreshold`).

### Examples

```python
given code snippet
```

Sometimes it may be useful to convert the data back into the original feature space. The `inverse_transform` function converts the binned data into the original feature space. Each value will be equal to the mean of the two bin edges.

```python
given code snippet
```

```python
given code snippet
```
**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**inverse_transform** *(Xt)*

Transform discretized data back to original feature space.

Note that this function does not regenerate the original data due to discretization rounding.

**Parameters**

- **Xt** [array-like of shape (n_samples, n_features), dtype={int, float}] Transformed data in the binned space.

**Returns**

- **Xinv** [ndarray, dtype={np.float32, np.float64}] Data in the original feature space.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** *(X)*

Discretize the data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), dtype={int, float}] Data to be discretized.

**Returns**
Xt  [:array, sparse matrix], dtype=[np.float32, np.float64]] Data in the binned space. Will be a sparse matrix if self.encode='onehot' and ndarray otherwise.

Examples using sklearn.preprocessing.KBinsDiscretizer

- Poisson regression and non-normal loss
- Tweedie regression on insurance claims
- Using KBinsDiscretizer to discretize continuous features
- Demonstrating the different strategies of KBinsDiscretizer
- Feature discretization

7.33.4 sklearn.preprocessing.KernelCenterer

class sklearn.preprocessing.KernelCenterer
Center a kernel matrix.

Let K(x, z) be a kernel defined by phi(x)^T phi(z), where phi is a function mapping x to a Hilbert space. KernelCenterer centers (i.e., normalize to have zero mean) the data without explicitly computing phi(x). It is equivalent to centering phi(x) with sklearn.preprocessing.StandardScaler(with_std=False).

Read more in the User Guide.

Attributes

- `K_fit_rows_` [array of shape (n_samples,)] Average of each column of kernel matrix.
- `K_fit_all_` [float] Average of kernel matrix.

Examples

```python
>>> from sklearn.preprocessing import KernelCenterer
>>> from sklearn.metrics.pairwise import pairwise_kernels

>>> X = [[ 1., -2., 2.],
       [ 2.,  1., 3.],
       [ 4.,  1., -2.]]

>>> K = pairwise_kernels(X, metric='linear')

>>> K
array([[ 9.,  2., -2.],
        [ 2., 14., -13.],
        [-2., -13., 21.]])

>>> transformer = KernelCenterer().fit(K)

>>> transformer.transform(K)
array([[ 5.,  0., -5.],
        [ 0., 14., -14.],
        [-5., -14., 19.]])
```
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(K[, y])</code></td>
<td>Fit KernelCenterer</td>
</tr>
<tr>
<td><code>fit_transform(X[, y])</code></td>

<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(K[, copy])</code></td>
<td>Center kernel matrix.</td>
</tr>
</tbody>
</table>

**fit** (K, y=None)
Fit KernelCenterer

Parameters

- **K** [ndarray of shape (n_samples, n_samples)] Kernel matrix.
- **y** [None] Ignored.

Returns

- **self** [object] Fitted transformer.

**fit_transform** (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**set_params**(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform(K, copy=True)
Center kernel matrix.

Parameters
K [ndarray of shape (n_samples1, n_samples2)] Kernel matrix.
copy [bool, default=True] Set to False to perform inplace computation.

Returns
K_new [ndarray of shape (n_samples1, n_samples2)]

7.33.5 sklearn.preprocessing.LabelBinarizer

class sklearn.preprocessing.LabelBinarizer(**kwargs)
Binarize labels in a one-vs-all fashion.

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer makes this process easy with the transform method.

At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. LabelBinarizer makes this easy with the inverse_transform method.

Read more in the User Guide.

Parameters
neg_label [int, default=0] Value with which negative labels must be encoded.
pos_label [int, default=1] Value with which positive labels must be encoded.
sparse_output [bool, default=False] True if the returned array from transform is desired to be in sparse CSR format.

Attributes
classes_ [ndarray of shape (n_classes,)] Holds the label for each class.
y_type_ [str] Represents the type of the target data as evaluated by
util.multiclass.type_of_target. Possible type are ‘continuous’, ‘continuous-multioutput’,
sparse_input_ [bool] True if the input data to transform is given as a sparse matrix, False otherwise.

See also:

label_binarize Function to perform the transform operation of LabelBinarizer with fixed classes.
OneHotEncoder Encode categorical features using a one-hot aka one-of-K scheme.
## Examples

```python
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 4, 2])
LabelBinarizer()
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
      [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```python
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
array([[1],
      [0],
      [0],
      [1]])
```

Passing a 2D matrix for multilabel classification

```python
>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer()
>>> lb.classes_
array([0, 1, 2])
>>> lb.transform([0, 1, 2, 1])
array([[1, 0, 0],
      [0, 1, 0],
      [0, 0, 1],
      [0, 1, 0]])
```

## Methods

- **fit(y)**
  Fit label binarizer.

- **fit_transform(y)**
  Fit label binarizer and transform multi-class labels to binary labels.

- **get_params([deep])**
  Get parameters for this estimator.

- **inverse_transform(Y[, threshold])**
  Transform binary labels back to multi-class labels.

- **set_params(**params)**
  Set the parameters of this estimator.

- **transform(y)**
  Transform multi-class labels to binary labels.

### fit (y)

**Parameters**

- **y** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification.

**Returns**

- **self** [returns an instance of self.]
**fit_transform***(y)*
Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

**Parameters**

- **y** [[ndarray, sparse matrix] of shape (n_samples,) or (n_samples, n_classes)] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

**Returns**

- **Y** [[ndarray, sparse matrix] of shape (n_samples, n_classes)] Shape will be (n_samples, 1) for binary problems. Sparse matrix will be of CSR format.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**inverse_transform**(Y, threshold=None)
Transform binary labels back to multi-class labels.

**Parameters**

- **Y** [[ndarray, sparse matrix] of shape (n_samples, n_classes)] Target values. All sparse matrices are converted to CSR before inverse transformation.
- **threshold** [float, default=None] Threshold used in the binary and multi-label cases. Use 0 when Y contains the output of decision_function (classifier). Use 0.5 when Y contains the output of predict_proba.
  
  If None, the threshold is assumed to be half way between neg_label and pos_label.

**Returns**

- **y** [[ndarray, sparse matrix] of shape (n_samples,)] Target values. Sparse matrix will be of CSR format.

**Notes**

In the case when the binary labels are fractional (probabilistic), inverse_transform chooses the class with the greatest value. Typically, this allows to use the output of a linear model’s decision_function method directly as the input of inverse_transform.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.
Returns

```python
self [estimator instance] Estimator instance.
transform (y)
```

Transform multi-class labels to binary labels.

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

Parameters

```python
y [[array, sparse matrix] of shape (n_samples,) or (n_samples, n_classes)] Target values.
The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.
```

Returns

```python
Y [[ndarray, sparse matrix] of shape (n_samples, n_classes)] Shape will be (n_samples, 1) for binary problems. Sparse matrix will be of CSR format.
```

7.33.6 sklearn.preprocessing.LabelEncoder

class sklearn.preprocessing.LabelEncoder

Encode target labels with value between 0 and n_classes-1.

This transformer should be used to encode target values, i.e. y, and not the input X.

Read more in the User Guide.

New in version 0.12.

Attributes

```python
classes_ [ndarray of shape (n_classes,)] Holds the label for each class.
```

See also:

OrdinalEncoder Encode categorical features using an ordinal encoding scheme.

OneHotEncoder Encode categorical features as a one-hot numeric array.

Examples

LabelEncoder can be used to normalize labels.

```python
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2])
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.
```python
>>> le = preprocessing.LabelEncoder()
>>> le.fit(['paris', 'paris', 'tokyo', 'amsterdam'])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(['tokyo', 'tokyo', 'paris'])
array([2, 2, 1])...
>>> list(le.inverse_transform([2, 2, 1]))
['tokyo', 'tokyo', 'paris']
```

### `fit(y)`
Fit label encoder.

**Parameters**

- `y` [array-like of shape (n_samples,)]: Target values.

**Returns**

- `self` [returns an instance of self.]

### `fit_transform(y)`
Fit labelencoder and return encoded labels.

**Parameters**

- `y` [array-like of shape (n_samples,): Target values.

**Returns**

- `y` [array-like of shape (n_samples,)]

### `get_params`(deep=True)
Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True]: If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict]: Parameter names mapped to their values.

### `inverse_transform(y)`
Transform labels back to original encoding.

**Parameters**

- `y` [ndarray of shape (n_samples,)]: Target values.

**Returns**
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params**  [dict] Estimator parameters.

**Returns**

self  [estimator instance] Estimator instance.

**transform** (**y**)  

Transform labels to normalized encoding.

**Parameters**

**y**  [array-like of shape (n_samples,)] Target values.

**Returns**

**y**  [array-like of shape (n_samples,)]

### 7.33.7 sklearn.preprocessing.MultiLabelBinarizer

class sklearn.preprocessing.MultiLabelBinarizer(**kwargs**)

Transform between iterable of iterables and a multilabel format.

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

**Parameters**

**classes**  [array-like of shape (n_classes,), default=None] Indicates an ordering for the class labels. All entries should be unique (cannot contain duplicate classes).

**sparse_output**  [bool, default=False] Set to True if output binary array is desired in CSR sparse format.

**Attributes**

**classes_**  [ndarray of shape (n_classes,)] A copy of the `classes` parameter when provided. Otherwise it corresponds to the sorted set of classes found when fitting.

See also:

OneHotEncoder  Encode categorical features using a one-hot aka one-of-K scheme.
Examples

```python
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[1, 1, 0],
       [0, 0, 1]])
>>> mlb.classes_
array([1, 2, 3])

>>> mlb.fit_transform([['sci-fi', 'thriller'], ['comedy']])
array([[0, 1, 1],
       [1, 0, 0]])
>>> list(mlb.classes_)
['comedy', 'sci-fi', 'thriller']
```

A common mistake is to pass in a list, which leads to the following issue:

```python
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit(['sci-fi', 'thriller', 'comedy'])
MultiLabelBinarizer()
>>> mlb.classes_
array(['-', 'c', 'd', 'e', 'f', 'h', 'i', 'l', 'm', 'o', 'r', 's', 't',
       'y'], dtype=object)
```

To correct this, the list of labels should be passed in as:

```python
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit([['sci-fi', 'thriller', 'comedy']])
MultiLabelBinarizer()
>>> mlb.classes_
array(['comedy', 'sci-fi', 'thriller'], dtype=object)
```

Methods

- **fit**
  - Signature: `fit(y)`
  - Fit the label sets binarizer, storing `classes_`.

- **fit_transform**
  - Signature: `fit_transform(y)`
  - Fit the label sets binarizer and transform the given label sets.

- **get_params**
  - Signature: `get_params([deep])`
  - Get parameters for this estimator.

- **inverse_transform**
  - Signature: `inverse_transform(yt)`
  - Transform the given indicator matrix into label sets.

- **set_params**
  - Signature: `set_params(**params)`
  - Set the parameters of this estimator.

- **transform**
  - Signature: `transform(y)`
  - Transform the given label sets.

Parameters

- `y` [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  - If the `classes` parameter is set, `y` will not be iterated.

Returns

- `self` [returns this MultiLabelBinarizer instance]
**fit_transform** *(y)*
Fit the label sets binarizer and transform the given label sets.

**Parameters**

- `y` [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  If the `classes` parameter is set, `y` will not be iterated.

**Returns**

- `y_indicator` [{ndarray, sparse matrix} of shape (n_samples, n_classes)] A matrix such that
  `y_indicator[i, j] = 1` if `classes_[j]` is in `y[i]`, and 0 otherwise. Sparse matrix will be of CSR format.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**inverse_transform**(yt)
Transform the given indicator matrix into label sets.

**Parameters**

- `yt` [{ndarray, sparse matrix} of shape (n_samples, n_classes)] A matrix containing only 1s and 0s.

**Returns**

- `y` [list of tuples] The set of labels for each sample such that `y[i]` consists of `classes_[j]` for each `yt[i, j] == 1`.

**set_params**(**params)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- `**params` [dict] Estimator parameters.

**Returns**

**transform**(y)
Transform the given label sets.

**Parameters**

- `y` [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  If the `classes` parameter is set, `y` will not be iterated.

**Returns**

- `y_indicator` [array or CSR matrix, shape (n_samples, n_classes)] A matrix such that
  `y_indicator[i, j] = 1` if `classes_[j]` is in `y[i]`, and 0 otherwise.
7.33.8 sklearn.preprocessing.MaxAbsScaler

class sklearn.preprocessing.MaxAbsScaler(**kwargs)

Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each
feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.

This scaler can also be applied to sparse CSR or CSC matrices.

New in version 0.17.

Parameters

- **copy** [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input
  is already a numpy array).

Attributes

- **scale_** [ndarray of shape (n_features,)] Per feature relative scaling of the data.
  New in version 0.17: scale_ attribute.
- **max_abs_** [ndarray of shape (n_features,)] Per feature maximum absolute value.
- **n_samples_seen_** [int] The number of samples processed by the estimator. Will be reset on
  new calls to fit, but increments across partial_fit calls.

See also:

maxabs_scale Equivalent function without the estimator API.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import MaxAbsScaler
>>> X = [[ 1., -1., 2.],
...     [ 2., 0., 0.],
...     [ 0., 1., -1.]]
>>> transformer = MaxAbsScaler().fit(X)
>>> transformer
MaxAbsScaler()
>>> transformer.transform(X)
array([[ 0.5, -1. , 1. ],
       [ 1. , 0. , 0. ],
       [ 0. , 1. , -0.5]])

**`fit(X, y=None)`**

Compute the maximum absolute value to be used for later scaling.

**Parameters**

- `X` {array-like, sparse matrix} of shape (n_samples, n_features): The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.
- `y` [None]: Ignored.

**Returns**

`self` [object]: Fitted scaler.

**`fit_transform(X, y=None, **fit_params)`**

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)]: Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None]: Target values (None for unsupervised transformations).
- `**fit_params` [dict]: Additional fit parameters.

**Returns**

`X_new` [ndarray array of shape (n_samples, n_features_new)]: Transformed array.

**`get_params(deep=True)`**

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True]: If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

`params` [dict]: Parameter names mapped to their values.

**`inverse_transform(X)`**

Scale back the data to the original representation

**Parameters**
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data that should be transformed back.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

partial_fit (X, y=None)
Online computation of max absolute value of X for later scaling.
All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.
y [None] Ignored.

Returns

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Scale the data

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data that should be scaled.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

Examples using sklearn.preprocessing.MaxAbsScaler

• Compare the effect of different scalers on data with outliers
7.33.9 sklearn.preprocessing.MinMaxScaler

class sklearn.preprocessing.MinMaxScaler(**kwargs)
Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, e.g. between zero and one.

The transformation is given by:

\[
X_{\text{std}} = (X - X.\text{min}(\text{axis}=0)) / (X.\text{max}(\text{axis}=0) - X.\text{min}(\text{axis}=0)) \\
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]

where min, max = feature_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the User Guide.

Parameters

- feature_range [tuple (min, max), default=(0, 1)] Desired range of transformed data.
- copy [bool, default=True] Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).
- clip: bool, default=False Set to True to clip transformed values of held-out data to provided feature range.
  New in version 0.24.

Attributes

- min_ [ndarray of shape (n_features,)] Per feature adjustment for minimum. Equivalent to min - X.min(axis=0) * self.scale_
- scale_ [ndarray of shape (n_features,)] Per feature relative scaling of the data. Equivalent to (max - min) / (X.max(axis=0) - X.min(axis=0))
  New in version 0.17: scale_ attribute.
- data_min_ [ndarray of shape (n_features,)] Per feature minimum seen in the data
  New in version 0.17: data_min_
- data_max_ [ndarray of shape (n_features,)] Per feature maximum seen in the data
  New in version 0.17: data_max_
- data_range_ [ndarray of shape (n_features,)] Per feature range (data_max_ - data_min_) seen in the data
  New in version 0.17: data_range_
- n_samples_seen_ [int] The number of samples processed by the estimator. It will be reset on new calls to fit, but increments across partial_fit calls.

See also:

minmax_scale Equivalent function without the estimator API.
Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import MinMaxScaler
>>> data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
>>> scaler = MinMaxScaler()
>>> print(scaler.fit(data))
MinMaxScaler()
>>> print(scaler.data_max_)
[ 1. 18.]
>>> print(scaler.transform(data))
[[0. 0. ]
 [0.25 0.25]
 [0.5 0.5 ]
 [1. 1. ]]
>>> print(scaler.transform([[2, 2]]))
[[1.5 0. ]]
```

**fit** *(X=\text{None})*

Compute the minimum and maximum to be used for later scaling.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.
- **y** [\text{None}] Ignored.

**Returns**

- **self** [object] Fitted scaler.

**fit_transform** *(X=\text{None}, **fit_params)***

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.
Parameters

**X** [array-like of shape (n_samples, n_features)] Input samples.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

**X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**inverse_transform**(X)

Undo the scaling of X according to feature_range.

Parameters

**X** [array-like of shape (n_samples, n_features)] Input data that will be transformed. It cannot be sparse.

Returns

**Xt** [ndarray of shape (n_samples, n_features)] Transformed data.

**partial_fit**(X, y=None)

Online computation of min and max on X for later scaling.

All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

Parameters

**X** [array-like of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** [None] Ignored.

Returns

**self** [object] Fitted scaler.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

**self** [estimator instance] Estimator instance.
transform $(X)$

Scale features of $X$ according to feature_range.

Parameters

$X$ [array-like of shape (n_samples, n_features)] Input data that will be transformed.

Returns

$X_t$ [ndarray of shape (n_samples, n_features)] Transformed data.

Examples using sklearn.preprocessing.MinMaxScaler

- Scalable learning with polynomial kernel aproximation
- Univariate Feature Selection
- Compare Stochastic learning strategies for MLPClassifier
- Compare the effect of different scalers on data with outliers

7.33.10 sklearn.preprocessing.Normalizer

class sklearn.preprocessing.Normalizer(**kwargs)

Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1, l2 or inf) equals one.

This transformer is able to work both with dense numpy arrays and scipy.sparse matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the User Guide.

Parameters

- **norm** [{‘l1’, ‘l2’, ‘max’}, default=’l2’] The norm to use to normalize each non zero sample. If norm=’max’ is used, values will be rescaled by the maximum of the absolute values.
- **copy** [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

normalize Equivalent function without the estimator API.
**Notes**

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**Examples**

```python
>>> from sklearn.preprocessing import Normalizer

>>> X = [[4, 1, 2, 2],
...      [1, 3, 9, 3],
...      [5, 7, 5, 1]]

>>> transformer = Normalizer().fit(X)  # fit does nothing.

>>> transformer
Normalizer()

>>> transformer.transform(X)
array([[0.8, 0.2, 0.4, 0.4],
       [0.1, 0.3, 0.9, 0.3],
       [0.5, 0.7, 0.5, 0.1]])
```

**Methods**

</tr>
</tbody>
</table>

**fit** (X, y=None)

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) The data to estimate the normalization parameters.
- **y** [None] Ignored.

**Returns**

- **self** [object] Fitted transformer.

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

generate sample data. (A)  "Sample data for a thousand

Examples using sklearn.preprocessing.Normalizer

- **Scalable learning with polynomial kernel approximation**
- **Compare the effect of different scalers on data with outliers**
- **Clustering text documents using k-means**
7.33.11 sklearn.preprocessing.OneHotEncoder

```python
class sklearn.preprocessing.OneHotEncoder(**kwargs)
```
Encode categorical features as a one-hot numeric array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by
categorical (discrete) features. The features are encoded using a one-hot (aka 'one-of-K' or 'dummy') encoding
scheme. This creates a binary column for each category and returns a sparse matrix or dense array (depending
on the sparse parameter)

By default, the encoder derives the categories based on the unique values in each feature. Alternatively, you can
also specify the categories manually.

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and
SVMs with the standard kernels.

Note: a one-hot encoding of y labels should use a LabelBinarizer instead.

Read more in the User Guide.

Changed in version 0.20.

**Parameters**

- **categories** ['auto' or a list of array-like, default='auto'] Categories (unique values) per feature:
  - 'auto' : Determine categories automatically from the training data.
  - list : categories[i] holds the categories expected in the ith column. The passed
categories should not mix strings and numeric values within a single feature, and should
be sorted in case of numeric values.

  The used categories can be found in the categories_ attribute.

  New in version 0.20.

- **drop** ['first', 'if_binary'] or a array-like of shape (n_features,), default=None] Specifies a
  methodology to use to drop one of the categories per feature. This is useful in situations
  where perfectly collinear features cause problems, such as when feeding the resulting data
  into a neural network or an unregularized regression.

  However, dropping one category breaks the symmetry of the original representation and can
  therefore induce a bias in downstream models, for instance for penalized linear classification
  or regression models.

  - None : retain all features (the default).
  - first' : drop the first category in each feature. If only one category is present, the feature
    will be dropped entirely.
  - 'if_binary' : drop the first category in each feature with two categories. Features with 1
    or more than 2 categories are left intact.

  array : drop[i] is the category in feature X[:, i] that should be dropped.

  Changed in version 0.23: Added option 'if_binary'.

- **sparse** [bool, default=True] Will return sparse matrix if set True else will return an array.

- **dtype** [number type, default=float] Desired dtype of output.

- **handle_unknown** ['error', 'ignore'], default='error'] Whether to raise an error or ignore if
  an unknown categorical feature is present during transform (default is to raise). When this
  parameter is set to 'ignore' and an unknown category is encountered during transform, the
resulting one-hot encoded columns for this feature will be all zeros. In the inverse transform, an unknown category will be denoted as None.

Attributes

- **categories_** [list of arrays] The categories of each feature determined during fitting (in order of the features in X and corresponding with the output of transform). This includes the category specified in drop (if any).

- **drop_idx_** [array of shape (n_features,)]
  - `drop_idx_[i]` is the index in `categories_[i]` of the category to be dropped for each feature.
  - `drop_idx_[i] = None` if no category is to be dropped from the feature with index i, e.g. when `drop='if_binary'` and the feature isn’t binary.
  - `drop_idx_ = None` if all the transformed features will be retained.

See also:

- **OrdinalEncoder** Performs an ordinal (integer) encoding of the categorical features.

- **sklearn.automl.feature_extraction.DictVectorizer** Performs a one-hot encoding of dictionary items (also handles string-valued features).

- **sklearn.automl.feature_extraction.FeatureHasher** Performs an approximate one-hot encoding of dictionary items or strings.

- **LabelBinarizer** Binarizes labels in a one-vs-all fashion.

- **MultiLabelBinarizer** Transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to a binary one-hot encoding.

```python
>>> from sklearn.preprocessing import OneHotEncoder
```

One can discard categories not seen during fit:

```python
>>> enc = OneHotEncoder(handle_unknown='ignore')
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
OneHotEncoder(handle_unknown='ignore')
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([[1, 2, 3], ['Male', 4]]).toarray()
array([[1, 0, 0, 0, 0],
       [0, 1, 0, 0, 0]])
>>> enc.inverse_transform([[0, 1, 0, 0, 0], [0, 0, 0, 1, 0]])
array([[None, 2]], dtype=object)
>>> enc.get_feature_names(['gender', 'group'])
array(['gender_Female', 'gender_Male', 'group_1', 'group_2', 'group_3'],
     dtype=object)
```
One can always drop the first column for each feature:

```python
>>> drop_enc = OneHotEncoder(drop='first').fit(X)
>>> drop_enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> drop_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 0., 0.],
       [1., 1., 0.]])
```

Or drop a column for feature only having 2 categories:

```python
>>> drop_binary_enc = OneHotEncoder(drop='if_binary').fit(X)
>>> drop_binary_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 1., 0., 0.],
       [1., 0., 1., 0.]])
```

### fit (X, y=None)

Fit OneHotEncoder to X.

**Parameters**

- **X** [array-like, shape [n_samples, n_features]] The data to determine the categories of each feature.
- **y** [None] Ignored. This parameter exists only for compatibility with Pipeline.

**Returns**

- **self**

### fit_transform (X, y=None)

Fit OneHotEncoder to X, then transform X.

Equivalent to fit(X).transform(X) but more convenient.

**Parameters**

- **X** [array-like, shape [n_samples, n_features]] The data to encode.
- **y** [None] Ignored. This parameter exists only for compatibility with Pipeline.

**Returns**

- **X_out** [sparse matrix if sparse=True else a 2-d array] Transformed input.

### get_feature_names (input_features=None)

Return feature names for output features.

**Parameters**

- **input_features** [None]
**input_features**  [list of str of shape (n_features,)] String names for input features if available. By default, “x0”, “x1”, … “xn_features” is used.

**Returns**

**output_feature_names**  [ndarray of shape (n_output_features,)] Array of feature names.

**get_params**  *(deep=True)*  
Get parameters for this estimator.

**Parameters**

**deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params**  [dict] Parameter names mapped to their values.

**inverse_transform** *(X)*  
Convert the data back to the original representation.

In case unknown categories are encountered (all zeros in the one-hot encoding), *None* is used to represent this category.

**Parameters**

**X**  [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed data.

**Returns**

**X_tr**  [array-like, shape [n_samples, n_features]] Inverse transformed array.

**set_params**  **(**params**)*  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params**  [dict] Estimator parameters.

**Returns**

self  [estimator instance] Estimator instance.

**transform** *(X)*  
Transform X using one-hot encoding.

**Parameters**

**X**  [array-like, shape [n_samples, n_features]] The data to encode.

**Returns**

**X_out**  [sparse matrix if sparse=True else a 2-d array] Transformed input.
Examples using `sklearn.preprocessing.OneHotEncoder`

- Release Highlights for scikit-learn 0.23
- Feature transformations with ensembles of trees
- Combine predictors using stacking
- Poisson regression and non-normal loss
- Tweedie regression on insurance claims
- Permutation Importance vs Random Forest Feature Importance (MDI)
- Common pitfalls in interpretation of coefficients of linear models
- Column Transformer with Mixed Types

### 7.33.12 sklearn.preprocessing.OrdinalEncoder

**class** `sklearn.preprocessing.OrdinalEncoder(**kwargs)`  
Encode categorical features as an integer array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are converted to ordinal integers. This results in a single column of integers (0 to n_categories - 1) per feature.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

- `categories`
  - `['auto' or a list of array-like, default='auto']`  
  Categories (unique values) per feature:
  - `auto` : Determine categories automatically from the training data.
  - `list` : `categories[i]` holds the categories expected in the ith column. The passed categories should not mix strings and numeric values, and should be sorted in case of numeric values.

  The used categories can be found in the `categories_` attribute.

- `dtype`
  - `[number type, default np.float64]` Desired dtype of output.

- `handle_unknown`
  - `[{'error', 'use_encoded_value'}, default='error']` When set to `error` an error will be raised in case an unknown categorical feature is present during transform. When set to `use_encoded_value`, the encoded value of unknown categories will be set to the value given for the parameter `unknown_value`. In `inverse_transform`, an unknown category will be denoted as None.

  New in version 0.24.

- `unknown_value`
  - `[int or np.nan, default=None]` When the parameter `handle_unknown` is set to `use_encoded_value`, this parameter is required and will set the encoded value of unknown categories. It has to be distinct from the values used to encode any of the categories in `fit`. If set to `np.nan`, the `dtype` parameter must be a float dtype.

  New in version 0.24.

**Attributes**
categories_ [list of arrays] The categories of each feature determined during fit (in order of the features in X and corresponding with the output of transform). This does not include categories that weren’t seen during fit.

See also:

OneHotEncoder Performs a one-hot encoding of categorical features.

LabelEncoder Encodes target labels with values between 0 and n_classes-1.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to an ordinal encoding.

>>> from sklearn.preprocessing import OrdinalEncoder
>>> enc = OrdinalEncoder()
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
OrdinalEncoder()
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([[('Female', 3), ('Male', 1)]])
array([[0., 2.],
       [1., 0.]])

fit (X, y=None)

Fit the OrdinalEncoder to X.

Parameters

- X [array-like, shape [n_samples, n_features]] The data to determine the categories of each feature.
- y [None] Ignored. This parameter exists only for compatibility with Pipeline.

Returns

self

fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.
Fits transformer to $X$ and $y$ with optional parameters `fit_params` and returns a transformed version of $X$.

**Parameters**

- $X$ [array-like of shape (n_samples, n_features)] Input samples.
- $y$ [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- $X_{\text{new}}$ [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

**inverse_transform**(X)

Convert the data back to the original representation.

**Parameters**

- $X$ [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed data.

**Returns**

- $X_{\text{tr}}$ [array-like, shape [n_samples, n_features]] Inverse transformed array.

**set_params**(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

**transform**(X)

Transform $X$ to ordinal codes.

**Parameters**

- $X$ [array-like, shape [n_samples, n_features]] The data to encode.

**Returns**

- $X_{\text{out}}$ [sparse matrix or a 2-d array] Transformed input.
Examples using `sklearn.preprocessing.OrdinalEncoder`

- Combine predictors using stacking
- Poisson regression and non-normal loss

### 7.33.13 sklearn.preprocessing.PolynomialFeatures

```python
class sklearn.preprocessing.PolynomialFeatures(**kwargs)
Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than or equal to the specified degree. For example, if an input sample is two dimensional and of the form [a, b], the degree-2 polynomial features are [1, a, b, a^2, ab, b^2].
```

**Parameters**

- `degree` [int, default=2] The degree of the polynomial features.
- `interaction_only` [bool, default=False] If true, only interaction features are produced: features that are products of at most `degree` distinct input features (so not `a[1] ** 2`, `a[0] * a[2] ** 3`, etc.).
- `include_bias` [bool, default=True] If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).
- `order` [str, default='C'] Order of output array in the dense case. ‘F’ order is faster to compute, but may slow down subsequent estimators.

**Attributes**

- `powers_` [ndarray of shape (n_output_features, n_input_features)] powers_[i, j] is the exponent of the jth input in the ith output.
- `n_input_features_` [int] The total number of input features.
- `n_output_features_` [int] The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

**Notes**

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See examples/linear_model/plot_polynomial_interpolation.py
**Examples**

```python
>>> import numpy as np
>>> from sklearn.preprocessing import PolynomialFeatures
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[ 1., 0., 1., 0., 0., 1.],
       [ 1., 2., 3., 4., 6., 9.],
       [ 1., 4., 5., 16., 20., 25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[ 1., 0., 1.],
       [ 1., 2., 3.],
       [ 1., 4., 5.]])
```

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X[, y])</code></td>
<td>Compute number of output features.</td>
</tr>
<tr>
<td><code>fit_transform(X[, y])</code></td>
<td>Fit to data, then transform it.</td>
</tr>
<tr>
<td><code>get_feature_names([input_features])</code></td>
<td>Return feature names for output features.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>

<td>Transform data to polynomial features.</td>
</tr>
</tbody>
</table>

**fit** *(X, y=None)*

Compute number of output features.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)] The data.
- **y** [None] Ignored.

**Returns**

- **self** [object] Fitted transformer.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**
X_new  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_feature_names (input_features=None)
Return feature names for output features

Parameters

input_features [list of str of shape (n_features,), default=None] String names for input features if available. By default, “x0”, “x1”, … “xn_features” is used.

Returns

output_feature_names [list of str of shape (n_output_features,)]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>_<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Transform data to polynomial features

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The data to transform, row by row.

Prefer CSR over CSC for sparse input (for speed), but CSC is required if the degree is 4 or higher. If the degree is less than 4 and the input format is CSC, it will be converted to CSR, have its polynomial features generated, then converted back to CSC.

If the degree is 2 or 3, the method described in “Leveraging Sparsity to Speed Up Polynomial Feature Expansions of CSR Matrices Using K-Simplex Numbers” by Andrew Nystrom and John Hughes is used, which is much faster than the method used on CSC input. For this reason, a CSC input will be converted to CSR, and the output will be converted back to CSC prior to being returned, hence the preference of CSR.

Returns

XP [(ndarray, sparse matrix) of shape (n_samples, NP)] The matrix of features, where NP is the number of polynomial features generated from the combination of inputs. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.
Examples using `sklearn.preprocessing.PolynomialFeatures`

- Polynomial interpolation
- Robust linear estimator fitting
- Poisson regression and non-normal loss
- Underfitting vs. Overfitting

### 7.33.14 sklearn.preprocessing.PowerTransformer

**class** `sklearn.preprocessing.PowerTransformer(**kwargs)`

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, PowerTransformer supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

See more in the *User Guide*.

New in version 0.20.

**Parameters**

- `method` ([`'yeo-johnson'`, `'box-cox'`], default=`'yeo-johnson'`) The power transform method. Available methods are:
  - `'yeo-johnson'` [1], works with positive and negative values
  - `'box-cox'` [2], only works with strictly positive values

- `standardize` [bool, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

- `copy` [bool, default=True] Set to False to perform inplace computation during transformation.

**Attributes**

- `lambdas_` [ndarray of float of shape (n_features,)] The parameters of the power transformation for the selected features.

See also:

- `power_transform` Equivalent function without the estimator API.
- `QuantileTransformer` Maps data to a standard normal distribution with the parameter `output_distribution='normal'`. 
Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

`fit (X, y=None)`

Estimate the optimal parameter lambda for each feature.

The optimal lambda parameter for minimizing skewness is estimated on each feature independently using maximum likelihood.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data used to estimate the optimal transformation parameters.
- **y** [None] Ignored.

**Returns**

- **self** [object] Fitted transformer.
**fit_transform** *(X, y=None)*

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters **fit_params** and returns a transformed version of *X*.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**inverse_transform** *(X)*

Apply the inverse power transformation using the fitted lambdas.

The inverse of the Box-Cox transformation is given by:

```python
if lambda_ == 0:
    X = exp (X_trans)
else:
    X = (X_trans * lambda_ + 1) ** (1 / lambda_)
```

The inverse of the Yeo-Johnson transformation is given by:

```python
if X >= 0 and lambda_ == 0:
    X = exp (X_trans) - 1
elif X >= 0 and lambda_ != 0:
    X = (X_trans * lambda_ + 1) ** (1 / lambda_) - 1
elif X < 0 and lambda_ != 2:
    X = 1 - (- (2 - lambda_) * X_trans + 1) ** (1 / (2 - lambda_))
else:
    X = 1 - exp (-X_trans)
```

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The transformed data.

**Returns**

- **X** [ndarray of shape (n_samples, n_features)] The original data.

**set_params**(**params**)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** *(X)*  
Apply the power transform to each feature using the fitted lambdas.

**Parameters**

X [array-like of shape (n_samples, n_features)] The data to be transformed using a power transformation.

**Returns**

X_trans [ndarray of shape (n_samples, n_features)] The transformed data.

**Examples using sklearn.preprocessing.PowerTransformer**

- Map data to a normal distribution
- Compare the effect of different scalers on data with outliers

**7.33.15 sklearn.preprocessing.QuantileTransformer**

**class** sklearn.preprocessing.QuantileTransformer(**kwargs**)

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the User Guide.

New in version 0.19.

**Parameters**

n_quantiles [int, default=1000 or n_samples] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n_quantiles is larger than the number of samples, n_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.

output_distribution [{'uniform', 'normal'}, default='uniform'] Marginal distribution for the transformed data. The choices are ‘uniform’ (default) or ‘normal’.
ignore_implicit_zeros [bool, default=False] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

subsample [int, default=1e5] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

random_state [int, RandomState instance or None, default=None] Determines random number generation for subsampling and smoothing noise. Please see subsample for more details. Pass an int for reproducible results across multiple function calls. See Glossary

copy [bool, default=True] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

Attributes

n_quantiles_ [int] The actual number of quantiles used to discretize the cumulative distribution function.

quantiles_ [ndarray of shape (n_quantiles, n_features)] The values corresponding the quantiles of reference.

references_ [ndarray of shape (n_quantiles, )] Quantiles of references.

See also:

quantile_transform Equivalent function without the estimator API.

PowerTransformer Perform mapping to a normal distribution using a power transform.

StandardScaler Perform standardization that is faster, but less robust to outliers.

RobustScaler Perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import QuantileTransformer
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> qt = QuantileTransformer(n_quantiles=10, random_state=0)
>>> qt.fit_transform(X)
array([...])
```

**fit (X, y=None)**

Compute the quantiles used for transforming.

Parameters

- **X**  
  [array-like, sparse matrix] of shape (n_samples, n_features]  
  The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse csc_matrix. Additionally, the sparse matrix needs to be nonnegative if ignore_implicit_zeros is False.

- **y**  [None] Ignored.

Returns

- **self**  [object] Fitted transformer.

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X**  [array-like of shape (n_samples, n_features)] Input samples.

- **y**  [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

- **fit_params**  [dict] Additional fit parameters.

Returns

- **X_new**  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params (deep=True)**

Get parameters for this estimator.

Parameters

- **deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params**  [dict] Parameter names mapped to their values.

**inverse_transform (X)**

Back-projection to the original space.

Parameters

- **X**  [array-like, sparse matrix] of shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into
a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is False.

**Returns**

- `Xt` ([ndarray, sparse matrix] of (n_samples, n_features)) The projected data.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

**transform** (X)
Feature-wise transformation of the data.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is False.

**Returns**

- `Xt` ([ndarray, sparse matrix] of shape (n_samples, n_features)) The projected data.

### Examples using `sklearn.preprocessing.QuantileTransformer`

- Partial Dependence and Individual Conditional Expectation Plots
- Effect of transforming the targets in regression model
- Map data to a normal distribution
- Compare the effect of different scalers on data with outliers

### 7.33.16 `sklearn.preprocessing.RobustScaler`

**class** `sklearn.preprocessing.RobustScaler(**kwargs)`
Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the `transform` method.

Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.
Parameters

**with_centering** [bool, default=True] If True, center the data before scaling. This will cause `transform` to raise an exception when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

**with_scaling** [bool, default=True] If True, scale the data to interquartile range.

**quantile_range** (tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0, default=(25.0, 75.0), == (1st quantile, 3rd quantile), == IQR) Quantile range used to calculate `scale_`. New in version 0.18.

**copy** [bool, default=True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

**unit_variance** [bool, default=False] If True, scale data so that normally distributed features have a variance of 1. In general, if the difference between the x-values of `q_max` and `q_min` for a standard normal distribution is greater than 1, the dataset will be scaled down. If less than 1, the dataset will be scaled up. New in version 0.24.

Attributes

**center_** [array of floats] The median value for each feature in the training set.

**scale_** [array of floats] The (scaled) interquartile range for each feature in the training set.

New in version 0.17: `scale_` attribute.

See also:

**robust_scale** Equivalent function without the estimator API.

**PCA** Further removes the linear correlation across features with `‘whiten=True’`.

Notes

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

Examples

```python
>>> from sklearn.preprocessing import RobustScaler
>>> X = [[ 1., -2., 2.],
     ... [-2., 1., 3.],
     ... [ 4., 1., -2.]]
>>> transformer = RobustScaler().fit(X)
>>> transformer
RobustScaler()
>>> transformer.transform(X)
(continues on next page)
```
Methods

**fit**(*X*, *y*)
Compute the median and quantiles to be used for scaling.

**fit_transform**(*X*, *y*)
Fit to data, then transform it.

**get_params**([*deep*])
Get parameters for this estimator.

**inverse_transform**(*X*)
Scale back the data to the original representation

**set_params**(**params**)
Set the parameters of this estimator.

**transform**(*X*)
Center and scale the data.

**fit**(*X*, *y=None*)
Compute the median and quantiles to be used for scaling.

**Parameters**

* X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to compute the median and quantiles used for later scaling along the features axis.

* y [None] Ignored.

**Returns**

**fit_transform**(*X*, *y=None*, **fit_params**)
Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit_params* and returns a transformed version of *X*.

**Parameters**

* X [array-like of shape (n_samples, n_features)] Input samples.

* y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

* X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(*deep=True*)
Get parameters for this estimator.

**Parameters**

* deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

* params [dict] Parameter names mapped to their values.
inverse_transform(X)
Scale back the data to the original representation

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The rescaled data to be transformed back.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Center and scale the data.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to scale along the specified axis.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

Examples using sklearn.preprocessing.RobustScaler

• Compare the effect of different scalers on data with outliers

7.33.17 sklearn.preprocessing.StandardScaler

class sklearn.preprocessing.StandardScaler(**kwargs)

Standardize features by removing the mean and scaling to unit variance

The standard score of a sample \( x \) is calculated as:

\[
 z = (x - u) / s
\]

where \( u \) is the mean of the training samples or zero if with_mean=False, and \( s \) is the standard deviation of the training samples or one if with_std=False.

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Mean and standard deviation are then stored to be used on later data using transform.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave badly if the individual features do not more or less look like standard normally distributed data (e.g. Gaussian with 0 mean and unit variance).
For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger than others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing `with_mean=False` to avoid breaking the sparsity structure of the data.

Read more in the *User Guide*.

**Parameters**

- **copy** [bool, default=True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

- **with_mean** [bool, default=True] If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

- **with_std** [bool, default=True] If True, scale the data to unit variance (or equivalently, unit standard deviation).

**Attributes**

- **scale_** [ndarray of shape (n_features,) or None] Per feature relative scaling of the data. This is calculated using `np.sqrt(var_)`. Equal to None when `with_std=False`.

  New in version 0.17: `scale_`

- **mean_** [ndarray of shape (n_features,) or None] The mean value for each feature in the training set. Equal to None when `with_mean=False`.

- **var_** [ndarray of shape (n_features,) or None] The variance for each feature in the training set. Used to compute `scale_`. Equal to None when `with_std=False`.

- **n_samples_seen_** [int or ndarray of shape (n_features,)] The number of samples processed by the estimator for each feature. If there are not missing samples, the `n_samples_seen` will be an integer, otherwise it will be an array. Will be reset on new calls to fit, but increments across `partial_fit` calls.

**See also:**

- **scale** Equivalent function without the estimator API.

- **PCA** Further removes the linear correlation across features with ‘whiten=True’.

**Notes**

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

We use a biased estimator for the standard deviation, equivalent to `numpy.std(x, ddof=0)`. Note that the choice of `ddof` is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

</table>

**fit** *(X, y=None, sample_weight=None)*

Compute the mean and std to be used for later scaling.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* The data used to compute the mean and standard deviation used for later scaling along the features axis.
- **y** *(None)* Ignored.
- **sample_weight** *(array-like of shape (n_samples,), default=None)* Individual weights for each sample. Works only if X is dense. It will raise a `NotImplementedError` if called with sparse X.

New in version 0.24: parameter `sample_weight` support to StandardScaler.

**Returns**

- **self** *(object)* Fitted scaler.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features)) Input samples.*
**y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

**X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**inverse_transform**(X, copy=None)
Scale back the data to the original representation

Parameters

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to scale along the features axis.

**copy** [bool, default=None] Copy the input X or not.

Returns

**X_tr** [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

**partial_fit**(X, y=None, sample_weight=None)
Online computation of mean and std on X for later scaling.

All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque. “Algorithms for computing the sample variance: Analysis and recommendations.” The American Statistician 37.3 (1983): 242-247:

Parameters

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** [None] Ignored.

**sample_weight** [array-like of shape (n_samples,), default=None] Individual weights for each sample. Works only if X is dense. It will raise a **NotImplementedError** if called with sparse X

New in version 0.24: parameter sample_weight support to StandardScaler.

Returns

**self** [object] Fitted scaler.

**set_params**(**params**)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** *(X, copy=None)*

Perform standardization by centering and scaling

**Parameters**

X [[array-like, sparse matrix of shape (n_samples, n_features)]] The data used to scale along the features axis.

copy [bool, default=None] Copy the input X or not.

**Returns**

X_tr [[ndarray, sparse matrix] of shape (n_samples, n_features)] Transformed array.

```python
preprocessing.add_dummy_feature(X, value=1.0)
```

Augment dataset with an additional dummy feature.

```python
preprocessing.binarize(X, *[, threshold, copy])
```

Boolean thresholding of array-like or scipy.sparse matrix.

```python
preprocessing.label_binarize(y, *[, classes])
```

Binarize labels in a one-vs-all fashion.

```python
preprocessing.maxabs_scale(X, *[, axis, copy])
```

Scale each feature to the [-1, 1] range without breaking the sparsity.

```python
preprocessing.minmax_scale(X, *[, axis])
```

Transform features by scaling each feature to a given range.

```python
preprocessing.normalize(X, *[, norm, axis, copy])
```

Scale input vectors individually to unit norm (vector length).

```python
preprocessing.quantile_transform(X, *[, axis, copy])
```

Transform features using quantiles information.

```python
preprocessing.robust_scale(X, *[, axis])
```

Standardize a dataset along any axis.

```python
preprocessing.scale(X, *[, axis, with_mean, with_std, copy])
```

Standardize a dataset along any axis.

```python
preprocessing.power_transform(X, *[, method])
```

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like.

### 7.33.18 sklearn.preprocessing.add_dummy_feature

**sklearn.preprocessing.add_dummy_feature**(X, value=1.0)

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* Data.
- **value** *(float)* Value to use for the dummy feature.

**Returns**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features + 1)* Same data with dummy feature added as first column.
Examples

```python
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[1., 0., 1.],
       [1., 1., 0.]])
```

### 7.33.19 sklearn.preprocessing.binarize

sklearn.preprocessing.binarize

```python
sklearn.preprocessing.binarize(X, *, threshold=0.0, copy=True)
```

Boolean thresholding of array-like or scipy.sparse matrix.

Read more in the User Guide.

**Parameters**

- `X` [array-like, sparse matrix] of shape (n_samples, n_features) The data to binarize, element by element. scipy.sparse matrices should be in CSR or CSC format to avoid an un-necessary copy.
- `threshold` [float, default=0.0] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.
- `copy` [bool, default=True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR / CSC matrix and if axis is 1).

**Returns**

- `X_tr` [ndarray, sparse matrix] of shape (n_samples, n_features) The transformed data.

**See also:**

* Binarizer* Performs binarization using the Transformer API (e.g. as part of a preprocessing Pipeline).

### 7.33.20 sklearn.preprocessing.label_binarize

sklearn.preprocessing.label_binarize

```python
sklearn.preprocessing.label_binarize(y, *, classes, neg_label=0, pos_label=1, sparse_output=False)
```

Binarize labels in a one-vs-all fashion.

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

**Parameters**

- `y` [array-like] Sequence of integer labels or multilabel data to encode.
- `classes` [array-like of shape (n_classes,)] Uniquely holds the label for each class.
- `neg_label` [int, default=0] Value with which negative labels must be encoded.
- `pos_label` [int, default=1] Value with which positive labels must be encoded.
- `sparse_output` [bool, default=False.] Set to true if output binary array is desired in CSR sparse format.

**Returns**

7.33. sklearn.preprocessing: Preprocessing and Normalization 2673
Y [ndarray, sparse matrix] of shape (n_samples, n_classes)] Shape will be (n_samples, 1) for binary problems. Sparse matrix will be of CSR format.

See also:

LabelBinarizer Class used to wrap the functionality of label_binarize and allow for fitting to classes independently of the transform operation.

Examples

```python
>>> from sklearn.preprocessing import label_binarize
g  array([[1, 0, 0, 0],
         [0, 0, 0, 1]]))
```

The class ordering is preserved:

```python
>>> label_binarize([1, 6], classes=[1, 6, 4, 2])
g  array([[1, 0, 0, 0],
         [0, 1, 0, 0]])
```

Binary targets transform to a column vector

```python
>>> label_binarize(['yes', 'no', 'no', 'yes'], classes=['no', 'yes'])
g  array([[1],
         [0],
         [0],
         [1]])
```

Examples using sklearn.preprocessing.label_binarize

- Receiver Operating Characteristic (ROC)
- Precision-Recall

7.33.21 sklearn.preprocessing.maxabs_scale

sklearn.preprocessing.maxabs_scale(X, *, axis=0, copy=True)
Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The data.

axis [int, default=0] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

copy [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

Returns
X_tr  [(ndarray, sparse matrix) of shape (n_samples, n_features)] The transformed data.

**Warning:** Risk of data leak Do not use `maxabs_scale` unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using `MaxAbsScaler` within a `Pipeline` in order to prevent most risks of data leaking: `pipe = make_pipeline(MaxAbsScaler(), LogisticRegression())`.

See also:

`MaxAbsScaler` Performs scaling to the [-1, 1] range using the Transformer API (e.g. as part of a preprocessing `Pipeline`).

**Notes**

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

### 7.33.22 sklearn.preprocessing.minmax_scale

`sklearn.preprocessing.minmax_scale` *(X, feature_range=0, 1, *, axis=0, copy=True)*

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by (when `axis=0`):

\[
X_{\text{std}} = (X - X.\min(\text{axis}=0)) / (X.\max(\text{axis}=0) - X.\min(\text{axis}=0))
\]

\[
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]

where min, max = feature_range.

The transformation is calculated as (when `axis=0`):

\[
X_{\text{scaled}} = \text{scale} \times X + \text{min} - X.\min(\text{axis}=0) \times \text{scale}
\]

where \( \text{scale} = (\text{max} - \text{min}) / (X.\max(\text{axis}=0) - X.\min(\text{axis}=0)) \)

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the *User Guide*.

New in version 0.17: `minmax_scale` function interface to `MinMaxScaler`.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data.
  - **feature_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.
  - **axis** [int, default=0] Axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
copy [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

Returns

X_tr [ndarray of shape (n_samples, n_features)] The transformed data.

Warning: Risk of data leak Do not use `minmax_scale` unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using `MinMaxScaler` within a `Pipeline` in order to prevent most risks of data leaking: `pipe = make_pipeline(MinMaxScaler(), LogisticRegression())`.

See also:

`MinMaxScaler` Performs scaling to a given range using the Transformer API (e.g. as part of a preprocessing `Pipeline`).

Notes

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

Examples using `sklearn.preprocessing.minmax_scale`

- Compare the effect of different scalers on data with outliers

7.33.23 `sklearn.preprocessing.normalize`

`sklearn.preprocessing.normalize(X, norm=’l2’, *, axis=1, copy=True, return_norm=False)`

Scale input vectors individually to unit norm (vector length).

Read more in the `User Guide`.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to normalize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

norm [{‘l1’, ‘l2’, ‘max’}, default=’l2’] The norm to use to normalize each non zero sample (or each non-zero feature if axis is 0).

axis [{0, 1}, default=1] axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.

copy [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

return_norm [bool, default=False] whether to return the computed norms

Returns

X [{ndarray, sparse matrix} of shape (n_samples, n_features)] Normalized input X.
norms [ndarray of shape (n_samples,) if axis=1 else (n_features,)] An array of norms along
given axis for X. When X is sparse, a NotImplementedError will be raised for norm ‘l1’ or
‘l2’.

See also:
Normalizer Performs normalization using the Transformer API (e.g. as part of a preprocessing
Pipeline).

Notes
For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

7.33.24 sklearn.preprocessing.quantile_transform

`sklearn.preprocessing.quantile_transform(X, *, axis=0, n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy=True)`

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature,
this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers:
this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution
function of a feature is used to map the original values to a uniform distribution. The obtained values are then
mapped to the desired output distribution using the associated quantile function. Features values of new/unseen
data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that
this transform is non-linear. It may distort linear correlations between variables measured at the same scale but
renders variables measured at different scales more directly comparable.

Read more in the User Guide.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The data to transform.

axis [int, default=0] Axis used to compute the means and standard deviations along. If 0, transform
each feature, otherwise (if 1) transform each sample.

n_quantiles [int, default=1000 or n_samples] Number of quantiles to be computed. It corre-
sponds to the number of landmarks used to discretize the cumulative distribution function.
If n_quantiles is larger than the number of samples, n_quantiles is set to the number of sam-
ple as a larger number of quantiles does not give a better approximation of the cumulative
distribution function estimator.

output_distribution [{'uniform', 'normal'}, default='uniform'] Marginal distribution for the
transformed data. The choices are ‘uniform’ (default) or ‘normal’.

ignore_implicit_zeros [bool, default=False] Only applies to sparse matrices. If True, the sparse
tables of the matrix are discarded to compute the quantile statistics. If False, these entries
are treated as zeros.

subsample [int, default=1e5] Maximum number of samples used to estimate the quantiles
for computational efficiency. Note that the subsampling procedure may differ for value-
identical sparse and dense matrices.
random_state  [int, RandomState instance or None, default=None] Determines random number
generation for subsampling and smoothing noise. Please see subsample for more details.
Pass an int for reproducible results across multiple function calls. See Glossary

copy  [bool, default=True] Set to False to perform inplace transformation and avoid a copy (if
the input is already a numpy array). If True, a copy of $X$ is transformed, leaving the original
$X$ unchanged

.. versionchanged:: 0.23  The default value of copy changed from False to True in 0.23.

Returns

$X_t$  [[ndarray, sparse matrix] of shape (n_samples, n_features)] The transformed data.

See also:

QuantileTransformer  Performs quantile-based scaling using the Transformer API (e.g. as part of a pre-
processing Pipeline).

power_transform  Maps data to a normal distribution using a power transformation.

scale  Performs standardization that is faster, but less robust to outliers.

robust_scale  Performs robust standardization that removes the influence of outliers but does not put out-
liers and inliers on the same scale.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

Warning:  Risk of data leak

Do not use quantile_transform unless you know what you are doing. A common mistake is to
apply it to the entire data before splitting into training and test sets. This will bias the model evaluation
because information would have leaked from the test set to the training set. In general, we recommend
using QuantileTransformer within a Pipeline in order to prevent most risks of data leaking:

```
pipe = make_pipeline(QuantileTransformer(), LogisticRegression())
```

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=0, copy=True)
array([...])
```
Examples using `sklearn.preprocessing.quantile_transform`

- Effect of transforming the targets in regression model

### 7.33.25 `sklearn.preprocessing.robust_scale`

```python
sklearn.preprocessing.robust_scale(X, *, axis=0, with_centering=True, with_scaling=True,
quantile_range=(25.0, 75.0), copy=True, unit_variance=False)
```

Standardize a dataset along any axis

Center to the median and component wise scale according to the interquartile range.

Read more in the [User Guide](#).

**Parameters**

- **X**  

- **axis**  
  [int, default=0] axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

- **with_centering**  
  [bool, default=True] If True, center the data before scaling.

- **with_scaling**  
  [bool, default=True] If True, scale the data to unit variance (or equivalently, unit standard deviation).

- **quantile_range**  
  [tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0] default=(25.0, 75.0), == (1st quantile, 3rd quantile), == IQR Quantile range used to calculate scale_.

  New in version 0.18.

- **copy**  
  [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

- **unit_variance**  
  [bool, default=False] If True, scale data so that normally distributed features have a variance of 1. In general, if the difference between the x-values of q_max and q_min for a standard normal distribution is greater than 1, the dataset will be scaled down. If less than 1, the dataset will be scaled up.

  New in version 0.24.

**Returns**

- **X_tr**  
  [ndarray, sparse matrix] of shape (n_samples, n_features) The transformed data.

**See also:**

- `RobustScaler` Perform centering and scaling using the Transformer API (e.g. as part of a preprocessing [Pipeline]).
**Notes**

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly `with_centering=False` (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call `X.toarray()` if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

**Warning:** Risk of data leak

Do not use `robust_scale` unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using `RobustScaler` within a `Pipeline` in order to prevent most risks of data leaking: `pipe = make_pipeline(RobustScaler(), LogisticRegression())`.

### 7.33.26 sklearn.preprocessing.scale

**sklearn.preprocessing.scale**

`sklearn.preprocessing.scale(X, *, axis=0, with_mean=True, with_std=True, copy=True)`  
Standardize a dataset along any axis.

Center to the mean and component wise scale to unit variance.

Read more in the User Guide.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The data to center and scale.
- **axis** [int, default=0] axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.
- **with_mean** [bool, default=True] If True, center the data before scaling.
- **with_std** [bool, default=True] If True, scale the data to unit variance (or equivalently, unit standard deviation).
- **copy** [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

**Returns**

- **X_tr** [[ndarray, sparse matrix] of shape (n_samples, n_features)] The transformed data.

**See also:**

- **StandardScaler** Performs scaling to unit variance using the Transformer API (e.g. as part of a preprocessing `Pipeline`).
Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_mean=False (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

We use a biased estimator for the standard deviation, equivalent to numpy.std(x, ddof=0). Note that the choice of ddof is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Warning: Risk of data leak

Do not use scale unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using StandardScaler within a Pipeline in order to prevent most risks of data leaking: pipe = make_pipeline(StandardScaler(), LogisticRegression()).

Examples using sklearn.preprocessing.scale

• A demo of K-Means clustering on the handwritten digits data

7.33.27 sklearn.preprocessing.power_transform

sklearn.preprocessing.power_transform(X, method='yeo-johnson', *, standardize=True, copy=True)

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, power_transform supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the User Guide.

Parameters

X [array-like of shape (n_samples, n_features)] The data to be transformed using a power transformation.

method [{'yeo-johnson', 'box-cox'}, default='yeo-johnson'] The power transform method. Available methods are:

• ‘yeo-johnson’ [1], works with positive and negative values
• ‘box-cox’ [2], only works with strictly positive values

Changed in version 0.23: The default value of the method parameter changed from ‘box-cox’ to ‘yeo-johnson’ in 0.23.

standardize [bool, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

copy [bool, default=True] Set to False to perform in-place computation during transformation.

Returns

X_trans [ndarray of shape (n_samples, n_features)] The transformed data.

See also:

PowerTransformer Equivalent transformation with the Transformer API (e.g. as part of a preprocessing Pipeline).

quantile_transform Maps data to a standard normal distribution with the parameter output_distribution='normal'.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

References

[1], [2]

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import power_transform
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(power_transform(data, method='box-cox'))
[[-1.332... -0.707...]
 [ 0.256... -0.707...]
 [ 1.076... 1.414...]]
```

Warning: Risk of data leak. Do not use power_transform unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using PowerTransformer within a Pipeline in order to prevent most risks of data leaking, e.g.: pipe = make_pipeline(PowerTransformer(), LogisticRegression()).
7.34 sklearn.random_projection: Random projection

Random Projection transformers.

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the Johnson-Lindenstrauss lemma (quoting Wikipedia):

> In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

User guide: See the Random Projection section for further details.

7.34.1 sklearn.random_projection.GaussianRandomProjection

class sklearn.random_projection.GaussianRandomProjection(**kwargs)

Reduce dimensionality through Gaussian random projection.

The components of the random matrix are drawn from N(0, 1 / n_components).

Read more in the User Guide.

New in version 0.13.

Parameters

- **n_components** [int or ‘auto’, default=’auto’] Dimensionality of the target projection space.
  
n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the **eps** parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

- **eps** [float, default=0.1] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’. The value should be strictly positive.

  Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

- **random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generator used to generate the projection matrix at fit time. Pass an int for reproducible output across multiple function calls. See Glossary.
Attributes

- `n_components_` [int] Concrete number of components computed when `n_components="auto"`.
- `components_` [ndarray of shape (n_components, n_features)] Random matrix used for the projection.

See also:

`SparseRandomProjection`

Examples

```python
>>> import numpy as np
>>> from sklearn.random_projection import GaussianRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = GaussianRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
```

Methods

- `fit(X, y=None)` Generate a sparse random projection matrix.
- `fit_transform(X, y=None, **fit_params)` Fit to data, then transform it.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Project the data by using matrix product with the random matrix

```python
fit(X, y=None)
Generate a sparse random projection matrix.

Parameters

- **X** [ndarray, sparse matrix] of shape (n_samples, n_features) Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.
- **y** Ignored

Returns

self

fit_transform(X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
**fit_params** [dict] Additional fit parameters.

Returns

- **X_new**: [ndarray array of shape (n_samples, n_features_new)] Transformed array.

---

**get_params** (*deep=True*)

Get parameters for this estimator.

Parameters

- **deep**: [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params**: [dict] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params**: [dict] Estimator parameters.

Returns

- **self**: [estimator instance] Estimator instance.

**transform** (*X*)

Project the data by using matrix product with the random matrix

Parameters

- **X**: [[ndarray, sparse matrix] of shape (n_samples, n_features)] The input data to project into a smaller dimensional space.

Returns

- **X_new**: [[ndarray, sparse matrix] of shape (n_samples, n_components)] Projected array.

---

### 7.34.2 sklearn.random_projection.SparseRandomProjection

**class** sklearn.random_projection.SparseRandomProjection(**kwargs**)

Reduce dimensionality through sparse random projection.

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note \( s = \frac{1}{\text{density}} \) the components of the random matrix are drawn from:

- \(-\sqrt{s} / \sqrt{n\_components}\) with probability \(1 / 2s\)
- 0 with probability \(1 - 1 / s\)
- \(+\sqrt{s} / \sqrt{n\_components}\) with probability \(1 / 2s\)

Read more in the [User Guide](#).

New in version 0.13.

Parameters
**n_components** [int or ‘auto’, default=’auto’] Dimensionality of the target projection space.

- n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the **eps** parameter.
- It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

**density** [float or ‘auto’, default=’auto’] Ratio in the range (0, 1] of non-zero component in the random projection matrix.

- If density = ‘auto’, the value is set to the minimum density as recommended by Ping Li et al.: 1 / sqrt(n_features).
- Use density = 1 / 3.0 if you want to reproduce the results from Achlioptas, 2001.

**eps** [float, default=0.1] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’. This value should be strictly positive.

- Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

**dense_output** [bool, default=False] If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse.

- In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.
- If False, the projected data uses a sparse representation if the input is sparse.

**random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generator used to generate the projection matrix at fit time. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Attributes

- **n_components_** [int] Concrete number of components computed when n_components=”auto”.
- **components_** [sparse matrix of shape (n_components, n_features)] Random matrix used for the projection. Sparse matrix will be of CSR format.
- **density_** [float in range 0.0 - 1.0] Concrete density computed from when density = “auto”.

**fit(X, y=None)**

Generate a sparse random projection matrix.

**Parameters**

- `X` ([ndarray, sparse matrix] of shape (n_samples, n_features)) Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.
- `y` Ignored

**Returns**

- `self`

**fit_transform(X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

****fit_params [dict] Additional fit parameters.

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=False)

Get parameters for this estimator.
Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it's possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Project the data by using matrix product with the random matrix

Parameters

X [ndarray, sparse matrix] of shape (n_samples, n_features) The input data to project into
a smaller dimensional space.

Returns

X_new [ndarray, sparse matrix] of shape (n_samples, n_components) Projected array.

Examples using sklearn.random_projection.SparseRandomProjection

• Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
• The Johnson-Lindenstrauss bound for embedding with random projections

sklearn.random_projection.johnson_lindenstrauss_min_dim(n_samples, *, eps=0.1)
Find a ‘safe’ number of components to randomly project to.

The distortion introduced by a random projection \( p \) only changes the distance between two points by a factor \((1 + \varepsilon)\) in an euclidean space with good probability. The projection \( p \) is an \( \varepsilon \)-embedding as defined by:

\[(1 - \varepsilon) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \varepsilon) \|u - v\|^2\]

Where \( u \) and \( v \) are any rows taken from a dataset of shape (n_samples, n_features), \( \varepsilon \) is in \([0, 1]\) and \( p \) is a projection by a random Gaussian \( N(0, 1) \) matrix of shape (n_components, n_features) (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the \( \varepsilon \)-embedding is given by:

\[n_{\text{components}} \geq 4 \log(n_{\text{samples}}) / (\varepsilon^2 / 2 - \varepsilon^3 / 3)\]
Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an eps-embedding.

Read more in the User Guide.

Parameters

- **n_samples** [int or array-like of int] Number of samples that should be a integer greater than 0. If an array is given, it will compute a safe number of components array-wise.
- **eps** [float or ndarray of shape (n_components,), dtype=float, default=0.1] Maximum distortion rate in the range (0, 1) as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

Returns

- **n_components** [int or ndarray of int] The minimal number of components to guarantee with good probability an eps-embedding with n_samples.

- The Johnson-Lindenstrauss bound for embedding with random projections

7.35 sklearn.semi_supervised: Semi-Supervised Learning

The sklearn.semi_supervised module implements semi-supervised learning algorithms. These algorithms utilized small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

User guide: See the Semi-Supervised section for further details.

```python
semi_supervised.LabelPropagation(**kwargs)
```

Label Propagation classifier

```python
semi_supervised.LabelSpreading(**kwargs)
```

LabelSpreading model for semi-supervised learning

7.35. sklearn.semi_supervised: Semi-Supervised Learning 2689
7.35.1 sklearn.semi_supervised.LabelPropagation

class sklearn.semi_supervised.LabelPropagation(**kwargs)
Label Propagation classifier

Parameters

- **kernel** : ['knn', 'rbf'] or callable, default='rbf'
  String identifier for kernel function to use or
  the kernel function itself. Only ‘rbf’ and ‘knn’ strings are valid inputs. The function passed
  should take two inputs, each of shape (n_samples, n_features), and return a (n_samples,
  n_samples) shaped weight matrix.

- **gamma** : float, default=20
  Parameter for rbf kernel.

- **n_neighbors** : int, default=7
  Parameter for knn kernel which need to be strictly positive.

- **max_iter** : int, default=1000
  Change maximum number of iterations allowed.

- **tol** : float, 1e-3
  Convergence tolerance: threshold to consider the system at steady state.

- **n_jobs** : int, default=None
  The number of parallel jobs to run.
  None means 1 unless in a
  joblib.parallel_backend context. -1 means using all processors. See
  Glossary for more details.

Attributes

- **X_** : ndarray of shape (n_samples, n_features)
  Input array.

- **classes_** : ndarray of shape (n_classes,)
  The distinct labels used in classifying instances.

- **label_distributions_** : ndarray of shape (n_samples, n_classes)
  Categorical distribution for
  each item.

- **transduction_** : ndarray of shape (n_samples)
  Label assigned to each item via the transduction.

- **n_iter_** : int
  Number of iterations run.

See also:

- LabelSpreading
  Alternate label propagation strategy more robust to noise.

### fit (*X, y*)

Fit a semi-supervised label propagation model based

All the input data is provided matrix *X* (labeled and unlabeled) and corresponding label matrix *y* with a
dedicated marker value for unlabeled samples.

#### Parameters

- **X** [array-like of shape (n_samples, n_features)] A matrix of shape (n_samples, n_samples) will be created from this.
- **y** [array-like of shape (n_samples,)] n_labeled_samples (unlabeled points are marked as -1) All unlabeled samples will be transductively assigned labels.

#### Returns

self [object]

### get_params (*deep=True*)

Get parameters for this estimator.

#### Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

#### Returns

params [dict] Parameter names mapped to their values.

### predict (*X*)

Performs inductive inference across the model.

#### Parameters

- **X** [array-like of shape (n_samples, n_features)] The data matrix.

#### Returns

y [ndarray of shape (n_samples,)] Predictions for input data.

### predict_proba (*X*)

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in *X* and each possible outcome seen during
training (categorical distribution).
Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

probabilities [ndarray of shape (n_samples, n_classes)] Normalized probability distributions across class labels.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.35.2 sklearn.semi_supervised.LabelSpreading

class sklearn.semi_supervised.LabelSpreading(**kwargs)
LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.

Read more in the User Guide.

Parameters

kernel [[‘knn’, ‘rbf’] or callable, default=’rbf’] String identifier for kernel function to use or the kernel function itself. Only ‘rbf’ and ‘knn’ strings are valid inputs. The function passed should take two inputs, each of shape (n_samples, n_features), and return a (n_samples, n_samples) shaped weight matrix.

gamma [float, default=20] Parameter for rbf kernel.

n_neighbors [int, default=7] Parameter for knn kernel which is a strictly positive integer.
alpha [float, default=0.2] Clamping factor. A value in (0, 1) that specifies the relative amount that an instance should adopt the information from its neighbors as opposed to its initial label. alpha=0 means keeping the initial label information; alpha=1 means replacing all initial information.

max_iter [int, default=30] Maximum number of iterations allowed.

tol [float, default=1e-3] Convergence tolerance: threshold to consider the system at steady state.

n_jobs [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

X_ [ndarray of shape (n_samples, n_features)] Input array.

classes_ [ndarray of shape (n_classes,)] The distinct labels used in classifying instances.

label_distributions_ [ndarray of shape (n_samples, n_classes)] Categorical distribution for each item.

transduction_ [ndarray of shape (n_samples,)] Label assigned to each item via the transduction.

n_iter_ [int] Number of iterations run.

#### sklearn.svm.LinearSVC

```python
class sklearn.svm.LinearSVC(**kwargs)
    Linear Support Vector Classification.
```

Similar to SVC with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

**Parameters**

- **penalty**: [‘l1’, ‘l2’], default=’l2’ Specifies the norm used in the penalization. The ‘l2’ penalty is the standard used in SVC. The ‘l1’ leads to \( \text{coef}_v \) vectors that are sparse.

- **loss**: [‘hinge’, ‘squared_hinge’], default=’squared_hinge’ Specifies the loss function. ‘hinge’ is the standard SVM loss (used e.g. by the SVC class) while ‘squared_hinge’ is the square of the hinge loss. The combination of `penalty='l1'` and `loss='hinge'` is not supported.

- **dual**: [bool, default=True] Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

- **tol**: [float, default=1e-4] Tolerance for stopping criteria.

- **C**: [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.

- **multi_class**: [‘ovr’, ‘crammer_singer’], default=’ovr’ Determines the multi-class strategy if y contains more than two classes. “ovr” trains n_classes one-vs-rest classifiers, while “crammer_singer” optimizes a joint objective over all classes. While crammer_singer is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If “crammer_singer” is chosen, the options loss, penalty and dual will be ignored.

- **fit_intercept**: [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

- **intercept_scaling**: [float, default=1] When self.fit_intercept is True, instance vector x becomes \([x, self.intercept_scaling]\), i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to 11/2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.
**class_weight** [dict or ‘balanced’, default=None] Set the parameter C of class i to "class_weight[i]"*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

**verbose** [int, default=0] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

**random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data for the dual coordinate descent (if `dual=True`). When `dual=False` the underlying implementation of LinearSVC is not random and `random_state` has no effect on the results. Pass an int for reproducible output across multiple function calls. See Glossary.

**max_iter** [int, default=1000] The maximum number of iterations to be run.

**Attributes**

**coef_** [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

**intercept_** [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

**classes_** [ndarray of shape (n_classes,)] The unique classes labels.

**n_iter_** [int] Maximum number of iterations run across all classes.

See also:

SVC Implementation of Support Vector Machine classifier using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does. Furthermore SVC multi-class mode is implemented using one vs one scheme while LinearSVC uses one vs the rest. It is possible to implement one vs the rest with SVC by using the OneVsRestClassifier wrapper. Finally SVC can fit dense data without memory copy if the input is C-contiguous. Sparse data will still incur memory copy though.

sklearn.linear_model.SGDClassifier SGDClassifier can optimize the same cost function as LinearSVC by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

The underlying implementation, liblinear, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

LIBLINEAR: A Library for Large Linear Classification

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_features=4, random_state=0)
>>> clf = make_pipeline(StandardScaler(),
                      LinearSVC(random_state=0, tol=1e-5))
>>> clf.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('linearsvc', LinearSVC(random_state=0, tol=1e-05))])

>>> print(clf.named_steps['linearsvc'].coef_)
[[0.141... 0.526... 0.679... 0.493...]]

>>> print(clf.named_steps['linearsvc'].intercept_)
[0.1693...]
>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

`decision_function(X)`

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

- `X [array-like or sparse matrix, shape (n_samples, n_features)]` Samples.

Returns

- `array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)` Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

`densify()`

Convert coefficient matrix to dense array format.
Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- `self` Fitted estimator.

**`fit`** *(X, y, sample_weight=None)*

Fit the model according to the given training data.

**Parameters**

- `X` [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- `y` [array-like of shape (n_samples,)] Target vector relative to X.
- `sample_weight` [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.18.

**Returns**

**`get_params`**(deep=True)

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**`predict`**(X)

Predict class labels for samples in X.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- `C` [array, shape [n_samples]] Predicted class label per sample.

**`score`**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Test samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `score` [float] Mean accuracy of `self.predict(X)` wrt. y.
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**sparsify** ()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

**Returns**

self Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call `densify`.

**Examples using sklearn.svm.LinearSVC**

- Scalable learning with polynomial kernel approximation
- Release Highlights for scikit-learn 0.22
- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Pipeline Anova SVM
- Univariate Feature Selection
- Explicit feature map approximation for RBF kernels
- Detection error tradeoff (DET) curve
- Balance model complexity and cross-validated score
- Precision-Recall
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Column Transformer with Heterogeneous Data Sources
- Feature discretization
• Plot the support vectors in LinearSVC
• Plot different SVM classifiers in the iris dataset
• Scaling the regularization parameter for SVCs
• Classification of text documents using sparse features

**sklearn.svm.LinearSVR**

```python
class sklearn.svm.LinearSVR(**kwargs)
```

Linear Support Vector Regression.

Similar to SVR with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input.

Read more in the User Guide.

New in version 0.16.

Parameters

- **epsilon** [float, default=0.0] Epsilon parameter in the epsilon-insensitive loss function. Note that the value of this parameter depends on the scale of the target variable y. If unsure, set epsilon=0.
- **tol** [float, default=1e-4] Tolerance for stopping criteria.
- **C** [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.
- **loss** [{'epsilon_insensitive', 'squared_epsilon_insensitive'}, default='epsilon_insensitive'] Specifies the loss function. The epsilon-insensitive loss (standard SVR) is the L1 loss, while the squared epsilon-insensitive loss (‘squared_epsilon_insensitive’) is the L2 loss.
- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).
- **intercept_scaling** [float, default=1.] When self.fit_intercept is True, instance vector x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.
- **dual** [bool, default=True] Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.
- **verbose** [int, default=0] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.
- **random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data. Pass an int for reproducible output across multiple function calls. See Glossary.
- **max_iter** [int, default=1000] The maximum number of iterations to be run.

Attributes
coef_ [ndarray of shape (n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coef_ is a readonly property derived from raw_coef_ that follows the internal memory layout of liblinear.

intercept_ [ndarray of shape (1) if n_classes == 2 else (n_classes)] Constants in decision function.

n_iter_ [int] Maximum number of iterations run across all classes.

See also:

**LinearSVC** Implementation of Support Vector Machine classifier using the same library as this class (liblinear).

**SVR** Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.

**sklearn.linear_model.SGDRegressor** SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

### Examples

```python
>>> from sklearn.svm import LinearSVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, random_state=0)

>>> regr = make_pipeline(StandardScaler(),
...                       LinearSVR(random_state=0, tol=1e-5))

>>> regr.fit(X, y)

Pipeline(steps=[('standardscaler', StandardScaler()),
                ('linearsvr', LinearSVR(random_state=0, tol=1e-5))])

>>> print(regr.named_steps['linearsvr'].coef_)
[18.582... 27.023... 44.357... 64.522...]

>>> print(regr.named_steps['linearsvr'].intercept_)
[-4...]

>>> print(regr.predict([[0, 0, 0, 0]]))
[-2.384...]
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X, y[, sample_weight])</code></td>
<td>Fit the model according to the given training data.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>predict(X)</code></td>
<td>Predict using the linear model.</td>
</tr>
<tr>
<td><code>score(X, y[, sample_weight])</code></td>
<td>Return the coefficient of determination $R^2$ of the prediction.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

```python
fit (X, y, sample_weight=None)
```
Fit the model according to the given training data.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target vector relative to X
- **sample_weight** [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**Returns**

- **self** [object] An instance of the estimator.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict**(X)

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $(y_{true} - y_{pred})** 2).sum()$ and $v$ is the total sum of squares $(y_{true} - y_{true}.mean())** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

`sklearn.svm.NuSVC`

class sklearn.svm.NuSVC (**kwargs)
Nu-Support Vector Classification.

Similar to SVC but uses a parameter to control the number of support vectors.

The implementation is based on libsvm.

Read more in the User Guide.

Parameters

nu [float, default=0.5] An upper bound on the fraction of margin errors (see User Guide) and a lower bound of the fraction of support vectors. Should be in the interval (0, 1).

kernel [{'linear', 'poly', 'rbf', 'sigmoid', 'precomputed'}, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma [{'scale', 'auto'}) or float, default='scale'] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

• if `gamma='scale'` (default) is passed then it uses $1 / (n_features * X.var())$ as value of gamma,

• if ‘auto’, uses $1 / n_features$.

Changed in version 0.22: The default value of `gamma` changed from ‘auto’ to ‘scale’.

coeff [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.
probability [bool, default=False] Whether to enable probability estimates. This must be enabled prior to calling fit, will slow down that method as it internally uses 5-fold cross-validation, and predict_proba may be inconsistent with predict. Read more in the User Guide.

tol [float, default=1e-3] Tolerance for stopping criterion.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

class_weight [{dict, ‘balanced’}, default=None] Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies as n_samples / (n_classes * np.bincount(y))

verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape [{‘ovo’, ‘ovr’}, default=’ovr’] Whether to return a one-vs-rest (‘ovr’) decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2). However, one-vs-one (‘ovo’) is always used as multi-class strategy. The parameter is ignored for binary classification.

Changed in version 0.19: decision_function_shape is ‘ovr’ by default.

New in version 0.17: decision_function_shape=’ovr’ is recommended.

Changed in version 0.17: Deprecated decision_function_shape=’ovo’ and None.

break_ties [bool, default=False] If true, decision_function_shape=’ovr’, and number of classes > 2, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

random_state [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when probability is False. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

class_weight_ [ndarray of shape (n_classes,)] Multipliers of parameter C of each class. Computed based on the class_weight parameter.

classes_ [ndarray of shape (n_classes,)] The unique classes labels.

coeef_ [ndarray of shape (n_classes * (n_classes - 1) / 2, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coeff_ is readonly property derived from dual_coef_ and support_vectors_.

dual_coef_ [ndarray of shape (n_classes - 1, n_SV)] Dual coefficients of the support vector in the decision function (see Mathematical formulation), multiplied by their targets. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the multi-class section of the User Guide for details.

fit_status_ [int] 0 if correctly fitted, 1 if the algorithm did not converge.
intercept_ [ndarray of shape (n_classes * (n_classes - 1) / 2,)] Constants in decision function.

support_ [ndarray of shape (n_SV,)] Indices of support vectors.

support_vectors_ [ndarray of shape (n_SV, n_features)] Support vectors.

n_support_ [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

fit_status_ [int] 0 if correctly fitted, 1 if the algorithm did not converge.

probA_ [ndarray of shape (n_classes * (n_classes - 1) / 2,)]

probB_ [ndarray of shape (n_classes * (n_classes - 1) / 2,)] If probability=True, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If probability=False, it’s an empty array. Platt scaling uses the logistic function 1 / (1 + exp(decision_value * probA_ + probB_)) where probA_ and probB_ are learned from the dataset [2]. For more information on the multiclass case and training procedure see section 8 of [1].

shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

</tr>
</tbody>
</table>

**decision_function** (X)

Evaluates the decision function for the samples in X.

**Parameters**

X [array-like of shape (n_samples, n_features)]

**Returns**

X [ndarray of shape (n_samples, n_classes * (n_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes).

**Notes**

If decision_function_shape='ovo', the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (coef_). See also this question for further details. If decision_function_shape='ovr', the decision function is a monotonic transformation of ovo decision function.

**fit** (X, y, sample_weight=None)

Fit the SVM model according to the given training data.

**Parameters**

X [{array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

ey [array-like of shape (n_samples,)] Target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

self [object]

**Notes**

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
**predict** *(X)*  
Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **y_pred** [ndarray of shape (n_samples,)] Class labels for samples in X.

**property predict_log_proba**  
Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

- **X** [array-like of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **T** [ndarray of shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**property predict_proba**  
Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **T** [ndarray of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.
Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

score (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.svm.NuSVC

• Non-linear SVM

sklearn.svm.NuSVR

class sklearn.svm.NuSVR(**kwargs)

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter nu to control the number of support vectors. However, unlike NuSVC, where nu replaces C, here nu replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the User Guide.

Parameters

nu [float, default=0.5] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

C [float, default=1.0] Penalty parameter C of the error term.
kernel ([‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’], default=’rbf’) Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma ([‘scale’, ‘auto’] or float, default=’scale’) Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
- if gamma=’scale’ (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
- if ‘auto’, uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

coeff0 [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

tol [float, default=1e-3] Tolerance for stopping criterion.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

Attributes

class_weight_ [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

coeff_ [ndarray of shape (1, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coeff_ is readonly property derived from dual_coef_ and support_vectors_.

dual_coef_ [ndarray of shape (1, n_SV)] Coefficients of the support vector in the decision function.

fit_status_ [int] 0 if correctly fitted, 1 otherwise (will raise warning)

intercept_ [ndarray of shape (1,)] Constants in decision function.

n_support_ [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

support_ [ndarray of shape (n_SV,)] Indices of support vectors.

support_vectors_ [ndarray of shape (n_SV, n_features)] Support vectors.

### fit(X, y, sample_weight=None)

Fit the SVM model according to the given training data.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples, n_samples)]
  Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- **y** [array-like of shape (n_samples,)]
  Target values (class labels in classification, real numbers in regression).
- **sample_weight** [array-like of shape (n_samples,), default=None]
  Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self** [object]
Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (deep=True)
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

predict (X)
Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

Parameters

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns

- **y_pred** [ndarray of shape (n_samples,)]

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict (X) wrt. y.
Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.svm.NuSVR

• Model Complexity Influence

sklearn.svm.OneClassSVM

class sklearn.svm.OneClassSVM(**kwargs)

Unsupervised Outlier Detection.

Estimate the support of a high-dimensional distribution.

The implementation is based on libsvm.

Read more in the User Guide.

Parameters

kernel [{'linear', 'poly', 'rbf', 'sigmoid', 'precomputed'}, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma [{'scale', 'auto'} or float, default='scale'] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

• if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,

• if ‘auto’, uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

coeff0 [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

tol [float, default=1e-3] Tolerance for stopping criterion.
nu [float, default=0.5] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

Attributes

class_weight_ [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

coef_ [ndarray of shape (1, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coef_ is readonly property derived from dual_coef_ and support_vectors_.

dual_coef_ [ndarray of shape (1, n_SV)] Coefficients of the support vectors in the decision function.

fit_status_ [int] 0 if correctly fitted, 1 otherwise (will raise warning)

intercept_ [ndarray of shape (1,)] Constant in the decision function.

n_support_ [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

offset_ [float] Offset used to define the decision function from the raw scores. We have the relation: decision_function = score_samples - offset_. The offset is the opposite of intercept_ and is provided for consistency with other outlier detection algorithms. New in version 0.20.

shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

support_ [ndarray of shape (n_SV,)] Indices of support vectors.

support_vectors_ [ndarray of shape (n_SV, n_features)] Support vectors.

Examples

```python
>>> from sklearn.svm import OneClassSVM
>>> X = [[0], [0.44], [0.45], [0.46], [1]]
>>> clf = OneClassSVM(gamma='auto').fit(X)
>>> clf.predict(X)
array([-1,  1,  1,  1, -1])
>>> clf.score_samples(X)
array([1.7798..., 2.0547..., 2.0556..., 2.0561..., 1.7332...])
```

**decision_function***(X)*

Signed distance to the separating hyperplane.

Signed distance is positive for an inlier and negative for an outlier.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data matrix.

**Returns**

- **dec** [ndarray of shape (n_samples,)] Returns the decision function of the samples.

**fit** *(X, y=None, sample_weight=None, **params)*

Detects the soft boundary of the set of samples X.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Set of samples, where n_samples is the number of samples and n_features is the number of features.
- **sample_weight** [array-like of shape (n_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.
- **y** [Ignored] not used, present for API consistency by convention.

**Returns**

- **self** [object]

**Notes**

If X is not a C-ordered contiguous array it is copied.

**fit_predict** *(X, y=None)*

Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

**Parameters**

- **X** [{array-like, sparse matrix, dataframe} of shape (n_samples, n_features)]
- **y** [Ignored] Not used, present for API consistency by convention.

**Returns**

- **y** [ndarray of shape (n_samples,)] 1 for inliers, -1 for outliers.

**get_params** *(deep=True)*

Get parameters for this estimator.
Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on samples in X.

For a one-class model, +1 or -1 is returned.

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples_test, n_samples_train) For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns

y_pred [ndarray of shape (n_samples,)] Class labels for samples in X.

score_samples (X)
Raw scoring function of the samples.

Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

score_samples [ndarray of shape (n_samples,)] Returns the (unshifted) scoring function of the samples.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.svm.OneClassSVM

- Libsvm GUI
sklearn.svm.SVC

class sklearn.svm.SVC(**kwargs)

C-Support Vector Classification.

The implementation is based on libsvm. The fit time scales at least quadratically with the number of samples and may be impractical beyond tens of thousands of samples. For large datasets consider using LinearSVC or SGDClassifier instead, possibly after a Nystroem transformer.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how gamma, coef0 and degree affect each other, see the corresponding section in the narrative documentation: Kernel functions.

Read more in the User Guide.

Parameters

C [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.

kernel [{'linear', 'poly', 'rbf', 'sigmoid', 'precomputed'}, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape (n_samples, n_samples).

degree [int, default=3] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma [{'scale', 'auto'} or float, default='scale'] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

• if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,

• if 'auto', uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from 'auto' to 'scale'.

coef0 [float, default=0.0] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

probability [bool, default=False] Whether to enable probability estimates. This must be enabled prior to calling fit, will slow down that method as it internally uses 5-fold cross-validation, and predict_proba may be inconsistent with predict. Read more in the User Guide.

tol [float, default=1e-3] Tolerance for stopping criterion.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

class_weight [dict or ‘balanced’, default=None] Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multi-threaded context.
**max_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

**decision_function_shape** ['ovo', 'ovr', default='ovr'] Whether to return a one-vs-rest ('ovr') decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2). However, one-vs-one ('ovo') is always used as multi-class strategy. The parameter is ignored for binary classification.

Changed in version 0.19: decision_function_shape is 'ovr' by default.

New in version 0.17: decision_function_shape='ovr' is recommended.

Changed in version 0.17: Deprecated decision_function_shape='ovo' and None.

**break_ties** [bool, default=False] If true, decision_function_shape='ovr', and number of classes > 2, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

**random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when probability is False. Pass an int for reproducible output across multiple function calls. See Glossary.

**Attributes**

- **class_weight_** [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

- **classes_** [ndarray of shape (n_classes,)] The classes labels.

- **coef_** [ndarray of shape (n_classes * (n_classes - 1) / 2, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

  - **coef_** is a readonly property derived from dual_coef_ and support_vectors_.

- **dual_coef_** [ndarray of shape (n_classes -1, n_SV)] Dual coefficients of the support vector in the decision function (see Mathematical formulation), multiplied by their targets. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the multi-class section of the User Guide for details.

- **fit_status_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

- **intercept_** [ndarray of shape (n_classes * (n_classes - 1) / 2,)] Constants in decision function.

- **support_** [ndarray of shape (n_SV)] Indices of support vectors.

- **support_vectors_** [ndarray of shape (n_SV, n_features)] Support vectors.

- **n_support_** [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

- **probA_** [ndarray of shape (n_classes * (n_classes - 1) / 2)]

- **probB_** [ndarray of shape (n_classes * (n_classes - 1) / 2)] If probability=True, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If probability=False, it's an empty array. Platt scaling uses the logistic function \( \frac{1}{1 + \exp(decision_value \times probA_ + probB_)} \) where probA_ and probB_ are learned from the dataset [2]. For more information on the multiclass case and training procedure see section 8 of [1].
shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

References

[1], [2]

Examples

```python
>>> import numpy as np
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler

>>> X = np.array([[[-1, -1], [-2, -1], [1, 1], [2, 1]]
>>> y = np.array([1, 2, 2, 2])
>>> from sklearn.svm import SVC

>>> clf = make_pipeline(StandardScaler(), SVC(gamma='auto'))
>>> clf.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()), ('svc', SVC(gamma='auto'))])

>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(X) Evaluates the decision function for the samples in X.

fit(X, y[, sample_weight]) Fit the SVM model according to the given training data.

get_params([deep]) Get parameters for this estimator.

predict(X) Perform classification on samples in X.

score(X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.

set_params(**params) Set the parameters of this estimator.

decision_function(X)

Evaluates the decision function for the samples in X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

X [ndarray of shape (n_samples, n_classes * (n_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes).
Notes

If decision_function_shape='ovo', the function values are proportional to the distance of the samples $X$ to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector ($\text{coef}_E$). See also this question for further details. If decision_function_shape='ovr', the decision function is a monotonic transformation of ovo decision function.

`fit`(X, y, sample_weight=None)

Fit the SVM model according to the given training data.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples)
  Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- **y** [array-like of shape (n_samples,)] Target values (class labels in classification, real numbers in regression).
- **sample_weight** [array-like of shape (n_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns

- **self** [object]

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

`get_params`(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

`predict`(X)

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns

- **y_pred** [ndarray of shape (n_samples,)] Class labels for samples in X.
property predict_log_proba

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters

X [array-like of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns

T [ndarray of shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

property predict_proba

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters

X [array-like of shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns

T [ndarray of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

score (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.
**params (params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>_<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using sklearn.svm.SVC

- Libsvm GUI

sklearn.svm.SVR

class sklearn.svm.SVR(**kwargs)

Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to datasets with more than a couple of 10000 samples. For large datasets consider using LinearSVR or SGDRegressor instead, possibly after a Nystroem transformer.

Read more in the User Guide.

**Parameters**

kernel [{'linear', 'poly', 'rbf', 'sigmoid', 'precomputed'}, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma [{'scale', 'auto'} or float, default='scale'] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

- if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
- if ‘auto’, uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

coeff0 [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

tol [float, default=1e-3] Tolerance for stopping criterion.

C [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.
epsilon [float, default=0.1] Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

Attributes

class_weight_ [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

coeff_ [ndarray of shape (1, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coeff_ is readonly property derived from dual_coef_ and support_vectors_.

dual_coef_ [ndarray of shape (1, n_SV)] Coefficients of the support vector in the decision function.

fit_status_ [int] 0 if correctly fitted, 1 otherwise (will raise warning)

intercept_ [ndarray of shape (1,)] Constants in decision function.

n_support_ [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

support_ [ndarray of shape (n_SV,)] Indices of support vectors.

support_vectors_ [ndarray of shape (n_SV, n_features)] Support vectors.

Examples

```python
>>> from sklearn.svm import SVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
```
>>> regr = make_pipeline(StandardScaler(), SVR(C=1.0, epsilon=0.2))
>>> regr.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('svr', SVR(epsilon=0.2))])

</tbody>
</table>

**fit**(X, y, sample_weight=None)

Fit the SVM model according to the given training data.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples))
  - Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

- **y** (array-like of shape (n_samples,))
  - Target values (class labels in classification, real numbers in regression).

- **sample_weight** ([array-like of shape (n_samples,]), default=None]
  - Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self** [object]

**Notes**

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True]
  - If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.
**predict** *(X)*  
Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **y_pred** [ndarray of shape (n_samples,)]

**score** *(X, y, sample_weight=None)*
Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares ((y_true - y_pred) ** 2).sum() and \( v \) is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] \( R^2 \) of self.predict(X) wrt. y.

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.
Examples using `sklearn.svm.SVR`

- Prediction Latency
- Comparison of kernel ridge regression and SVR
- Support Vector Regression (SVR) using linear and non-linear kernels

```python
svm.l1_min_c(X, y, *, loss='squared_hinge', fit_intercept=True, intercept_scaling=1.0)
```

Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty. This applies to l1 penalized classifiers, such as LinearSVC with penalty='l1' and linear_model.LogisticRegression with penalty='l1'.

This value is valid if class_weight parameter in fit() is not set.

**Parameters**

- `X` [array-like, sparse matrix] of shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like of shape (n_samples,)] Target vector relative to X.
- `loss` ['squared_hinge', 'log'], default='squared_hinge'] Specifies the loss function. With 'squared_hinge' it is the squared hinge loss (a.k.a. L2 loss). With 'log' it is the loss of logistic regression models.
- `fit_intercept` [bool, default=True] Specifies if the intercept should be fitted by the model. It must match the fit() method parameter.
- `intercept_scaling` [float, default=1.0] when fit_intercept is True, instance vector x becomes [x, intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. It must match the fit() method parameter.

**Returns**

- `l1_min_c` [float] minimum value for C

Examples using `sklearn.svm.l1_min_c`

- Regularization path of L1- Logistic Regression
# 7.37 sklearn.tree: Decision Trees

The `sklearn.tree` module includes decision tree-based models for classification and regression.

**User guide:** See the `Decision Trees` section for further details.

## 7.37.1 sklearn.tree.DecisionTreeClassifier

### class sklearn.tree.DecisionTreeClassifier(**kwargs)

A decision tree classifier.

Read more in the [User Guide](#).

**Parameters**

- **criterion** ([“gini”, “entropy”], default=”gini”) The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.
- **splitter** ([“best”, “random”], default=”best”) The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.
- **max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.
- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:
  - If int, then consider min_samples_split as the minimum number.
  - If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

  Changed in version 0.18: Added float values for fractions.

- **min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
  - If int, then consider min_samples_leaf as the minimum number.
  - If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

  Changed in version 0.18: Added float values for fractions.

- **min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

- **max_features** [int, float or (“auto”, “sqrt”, “log2”), default=None] The number of features to consider when looking for the best split:
• If int, then consider \texttt{max_features} features at each split.
• If float, then \texttt{max_features} is a fraction and \texttt{int(max_features * n_features)} features are considered at each split.
• If “auto”, then \texttt{max_features=\sqrt{n_features}}.
• If “sqrt”, then \texttt{max_features=\sqrt{n_features}}.
• If “log2”, then \texttt{max_features=log2(n_features)}.
• If None, then \texttt{max_features=n_features}.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than \texttt{max_features} features.

\texttt{random_state} [int, RandomState instance or None, default=None] Controls the randomness of the estimator. The features are always randomly permuted at each split, even if \texttt{splitter} is set to "best". When \texttt{max_features < n_features}, the algorithm will select \texttt{max_features} at random at each split before finding the best split among them. But the best found split may vary across different runs, even if \texttt{max_features=n_features}. That is the case, if the improvement of the criterion is identical for several splits and one split has to be selected at random. To obtain a deterministic behaviour during fitting, \texttt{random_state} has to be fixed to an integer. See Glossary for details.

\texttt{max_leaf_nodes} [int, default=None] Grow a tree with \texttt{max_leaf_nodes} in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

\texttt{min_impurity_decrease} [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right impurity} \\
- \frac{N_{t,L}}{N_t} \times \text{left impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,R}\) and \(N_{t,L}\) all refer to the weighted sum, if \texttt{sample_weight} is passed.

New in version 0.19.

\texttt{min_impurity_split} [float, default=0] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: \texttt{min_impurity_split} has been deprecated in favor of \texttt{min_impurity_decrease} in 0.19. The default value of \texttt{min_impurity_split} has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use \texttt{min_impurity_decrease} instead.

\texttt{class_weight} [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form \{\texttt{class_label}: \texttt{weight}\}. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of \(y\).

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be \([\{0: 1, 1: 1\}, \{0: 1, 1: 5\}, \{0: 1, 1: 1\}, \{0: 1, 1: 1\}]\) instead of \([\{1:1\}, \{2:5\}, \{3:1\}, \{4:1\}]\).
The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as \( \frac{n_{\text{samples}}}{(n_{\text{classes}} \times \text{np.bincount}(y))} \)

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See *Minimal Cost-Complexity Pruning* for details.

New in version 0.22.

**Attributes**

- **classes_** [ndarray of shape (n_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.
- **max_features_** [int] The inferred value of max_features.
- **n_classes_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **tree_** [Tree instance] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

**See also:**

- **DecisionTreeRegressor** A decision tree regressor.

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The predict method operates using the numpy.argmax function on the outputs of predict_proba. This means that in case the highest predicted probabilities are tied, the classifier will predict the tied class with the lowest index in classes_.

**apply** *(X, check_input=True)*

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **X_leaves** [array-like of shape (n_samples,)] For each datapoint x in X, return the index of
the leaf \( x \) ends up in. Leaves are numbered within \([0; \textit{self.tree_.node_count})\), possibly with gaps in the numbering.

**cost_complexity_pruning_path** \((X, y, \text{sample_weight}=\text{None})\)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See [Minimal Cost-Complexity Pruning](#) for details on the pruning process.

**Parameters**

- **X** \([\text{array-like, sparse matrix}] \text{ of shape (n_samples, n_features)}\) The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.
- **y** \([\text{array-like of shape (n_samples,)} or \text{ (n_samples, n_outputs)}]\) The target values (class labels) as integers or strings.
- **sample_weight** \([\text{array-like of shape (n_samples,)}, \text{default=}\text{None}]\) Sample weights. If `None`, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- **ccp_path** \([\text{Bunch}]\) Dictionary-like object, with the following attributes.
  - **ccp_alphas** \([\text{ndarray}]\) Effective alphas of subtree during pruning.
  - **impurities** \([\text{ndarray}]\) Sum of the impurities of the subtree leaves for the corresponding alpha value in `ccp_alphas`.

**decision_path** \((X, \text{check_input}=\text{True})\)

Return the decision path in the tree.

New in version 0.18.

**Parameters**

- **X** \([\text{array-like, sparse matrix}] \text{ of shape (n_samples, n_features)}\) The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.
- **check_input** [bool, default=\text{True}] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **indicator** \([\text{sparse matrix of shape (n_samples, n_nodes)}]\) Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature_importances_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See [sklearn.inspection.permutation_importance](#) as an alternative.

**Returns**

- **feature_importances_** \([\text{ndarray of shape (n_features,)})\] Normalized total reduction of criteria by feature (Gini importance).
`fit(X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')`

Build a decision tree classifier from the training set \((X, y)\).

**Parameters**

- **X** [[array-like, sparse matrix] of shape \((n\_samples, n\_features)\)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

- **y** [array-like of shape \((n\_samples,)\) or \((n\_samples, n\_outputs)\)] The target values (class labels) as integers or strings.

- **sample_weight** [array-like of shape \((n\_samples,)\), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

- **X_idx_sorted** [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in v0.26.

**Returns**

- **self** [DecisionTreeClassifier] Fitted estimator.

`get_depth()`

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**Returns**

- **self.tree_.max_depth** [int] The maximum depth of the tree.

`get_n_leaves()`

Return the number of leaves of the decision tree.

**Returns**

- **self.tree_.n_leaves** [int] Number of leaves.

`get_params(deep=True)`

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

`predict(X, check_input=True)`

Predict class or regression value for \(X\).

For a classification model, the predicted class for each sample in \(X\) is returned. For a regression model, the predicted value based on \(X\) is returned.

**Parameters**
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

predict_log_proba (X)
Predict class log-probabilities of the input samples X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba (X, check_input=True)
Predict class probabilities of the input samples X.
The predicted class probability is the fraction of samples of the same class in a leaf.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using `sklearn.tree.DecisionTreeClassifier`

- Classifier comparison

### 7.37.2 `sklearn.tree.DecisionTreeRegressor`

**class** `sklearn.tree.DecisionTreeRegressor(**kwargs)`  
A decision tree regressor.

Read more in the User Guide.

**Parameters**

**criterion** [{“mse”, “friedman_mse”, “mae”}, default=”mse”] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion and minimizes the L2 loss using the mean of each terminal node, “friedman_mse”, which uses mean squared error with Friedman’s improvement score for potential splits, and “mae” for the mean absolute error, which minimizes the L1 loss using the median of each terminal node.

New in version 0.18: Mean Absolute Error (MAE) criterion.

**splitter** [{“best”, “random”}, default=”best”] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

**max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.
**min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider *min_samples_split* as the minimum number.
- If float, then *min_samples_split* is a fraction and \( \text{ceil}(\text{min_samples_split} \times n\_samples) \) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least *min_samples_leaf* training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression:

- If int, then consider *min_samples_leaf* as the minimum number.
- If float, then *min_samples_leaf* is a fraction and \( \text{ceil}(\text{min_samples_leaf} \times n\_samples) \) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when *sample_weight* is not provided.

**max_features** [int, float or {“auto”, “sqrt”, “log2”}, default=None] The number of features to consider when looking for the best split:

- If int, then consider *max_features* features at each split.
- If float, then *max_features* is a fraction and \( \text{int}(\text{max_features} \times n\_features) \) features are considered at each split.
- If “auto”, then *max_features*=*n_features*.
- If “sqrt”, then *max_features*=\( \sqrt{n\_features} \).
- If “log2”, then *max_features*=\( \log_2(n\_features) \).
- If None, then *max_features*=*n_features*.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than *max_features* features.

**random_state** [int, RandomState instance or None, default=None] Controls the randomness of the estimator. The features are always randomly permuted at each split, even if *splitter* is set to "best". When *max_features* < *n_features*, the algorithm will select *max_features* at random at each split before finding the best split among them. But the best found split may vary across different runs, even if *max_features* = *n_features*. That is the case, if the improvement of the criterion is identical for several splits and one split has to be selected at random. To obtain a deterministic behaviour during fitting, *random_state* has to be fixed to an integer. See *Glossary* for details.

**max_leaf_nodes** [int, default=None] Grow a tree with *max_leaf_nodes* in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:
\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t\_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t\_L}}{N_t} \times \text{left\_impurity})
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t\_L} \) is the number of samples in the left child, and \( N_{t\_R} \) is the number of samples in the right child.

\( N, N_t, N_{t\_R} \) and \( N_{t\_L} \) all refer to the weighted sum, if \text{sample\_weight} is passed.

New in version 0.19.

\textbf{min\_impurity\_split} [float, default=0] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: \text{min\_impurity\_split} has been deprecated in favor of \text{min\_impurity\_decrease} in 0.19. The default value of \text{min\_impurity\_split} has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use \text{min\_impurity\_decrease} instead.

\textbf{ccp\_alpha} [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than \text{ccp\_alpha} will be chosen. By default, no pruning is performed. See \text{Minimal Cost-Complexity Pruning} for details.

New in version 0.22.

\textbf{Attributes}

\textit{feature\_importances\_} [ndarray of shape (n\_features,)] Return the feature importances.

\textit{max\_features\_} [int] The inferred value of \text{max\_features}.

\textit{n\_features\_} [int] The number of features when \text{fit} is performed.

\textit{n\_outputs\_} [int] The number of outputs when \text{fit} is performed.

\textit{tree\_} [Tree instance] The underlying Tree object. Please refer to \text{help(sklearn.tree.\_tree.Tree)} for attributes of Tree object and \text{Understanding the decision tree structure} for basic usage of these attributes.

See also:

\textit{DecisionTreeClassifier} A decision tree classifier.

\textbf{Notes}

The default values for the parameters controlling the size of the trees (e.g. \text{max\_depth}, \text{min\_samples\_leaf}, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

### `apply (X, check_input=True)`

Return the index of the leaf that each sample is predicted as.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **X_leaves** [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within $[0; \text{self.tree_.node_count})$, possibly with gaps in the numbering.
cost_complexity_pruning_path \((X, y, \text{sample_weight}=\text{None})\)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

**Parameters**

- **\(X\)** [array-like, sparse matrix] of shape \((n\_samples, n\_features)\) The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

- **\(y\)** [array-like of shape \((n\_samples,)\) or \((n\_samples, n\_outputs)\)] The target values (class labels) as integers or strings.

- **\(\text{sample_weight}\)** [array-like of shape \((n\_samples,)\), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- **\(\text{ccp\_path}\)** [Bunch] Dictionary-like object, with the following attributes.
  - **\(\text{ccp\_alphas}\)** [ndarray] Effective alphas of subtree during pruning.
  - **\(\text{impurities}\)** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in `ccp_alphas`.

decision_path \((X, \text{check\_input}=\text{True})\)

Return the decision path in the tree.

New in version 0.18.

**Parameters**

- **\(X\)** [array-like, sparse matrix] of shape \((n\_samples, n\_features)\) The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

- **\(\text{check\_input}\)** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **\(\text{indicator}\)** [sparse matrix of shape \((n\_samples, n\_nodes)\)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

**Returns**

- **\(\text{feature\_importances}\)** [ndarray of shape \((n\_features,)\)] Normalized total reduction of criterion by feature (Gini importance).

fit \((X, y, \text{sample\_weight}=\text{None}, \text{check\_input}=\text{True}, X\_idx\_sorted='\text{deprecated}')\)

Build a decision tree regressor from the training set \((X, y)\).

**Parameters**
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (real numbers). Use dtype=np.float64 and order='C' for maximum efficiency.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted  [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in v0.26.

Deprecated since version 0.24.

Returns

self  [DecisionTreeRegressor] Fitted estimator.

get_depth ()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

self.tree_.max_depth  [int] The maximum depth of the tree.

get_n_leaves ()

Return the number of leaves of the decision tree.

Returns

self.tree_.n_leaves  [int] Number of leaves.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

predict (X, check_input=True)

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y\_true - y\_pred)**2)$ and $v$ is the total sum of squares $\sum((y\_true - y\_true.mean())**2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.tree.DecisionTreeRegressor

- Release Highlights for scikit-learn 0.22
- Decision Tree Regression
- Multi-output Decision Tree Regression
- Decision Tree Regression with AdaBoost
- Single estimator versus bagging: bias-variance decomposition
- Advanced Plotting With Partial Dependence
• Imputing missing values with variants of IterativeImputer
• Using KBinsDiscretizer to discretize continuous features

7.37.3 sklearn.tree.ExtraTreeClassifier

class sklearn.tree.ExtraTreeClassifier(**kwargs)
An extremely randomized tree classifier.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate
the samples of a node into two groups, random splits are drawn for each of the max_features randomly
selected features and the best split among those is chosen. When max_features is set 1, this amounts to
building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.
Read more in the User Guide.

Parameters

criterion [“gini”, “entropy”], default=”gini” The function to measure the quality of a split.
Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.
splitter [“random”, “best”], default=”random” The strategy used to choose the split at each
node. Supported strategies are “best” to choose the best split and “random” to choose the
best random split.
max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are ex-
panded until all leaves are pure or until all leaves contain less than min_samples_split sam-
pies.
min_samples_split [int or float, default=2] The minimum number of samples required to split
an internal node:
  • If int, then consider min_samples_split as the minimum number.
  • If float, then min_samples_split is a fraction and ceil(min_samples_split
      * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.
min_samples_leaf [int or float, default=1] The minimum number of samples required to be
at a leaf node. A split point at any depth will only be considered if it leaves at least
min_samples_leaf training samples in each of the left and right branches. This may
have the effect of smoothing the model, especially in regression.
  • If int, then consider min_samples_leaf as the minimum number.
  • If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf
      * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.
min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total
of weights (of all the input samples) required to be at a leaf node. Samples have equal weight
when sample_weight is not provided.
max_features [int, float, {“auto”, “sqrt”, “log2”} or None, default=”auto”] The number of
features to consider when looking for the best split:
  • If int, then consider max_features features at each split.
• If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
• If “auto”, then `max_features=sqrt(n_features)`.
• If “sqrt”, then `max_features=sqrt(n_features)`.
• If “log2”, then `max_features=log2(n_features)`.
• If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

`random_state` [int, RandomState instance or None, default=None] Used to pick randomly the `max_features` used at each split. See Glossary for details.

`max_leaf_nodes` [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

`min_impurity_decrease` [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity} \right)
$$

where $N$ is the total number of samples, $N_t$ is the number of samples at the current node, $N_{t,L}$ is the number of samples in the left child, and $N_{t,R}$ is the number of samples in the right child.

$N, N_t, N_{t,R}$ and $N_{t,L}$ all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

`min_impurity_split` [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

`class_weight` [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form `{class_label: weight}`. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[{1:1}, {2:5}, {3:1}, {4:1}]`.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.
**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

Attributes

- **classes_** [ndarray of shape (n_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
- **max_features_** [int] The inferred value of max_features.
- **n_classes_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).
- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **tree_** [Tree instance] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and Understanding the decision tree structure for basic usage of these attributes.

See also:

- **ExtraTreeRegressor** An extremely randomized tree regressor.
- **sklearn.ensemble.ExtraTreesClassifier** An extra-trees classifier.
- **sklearn.ensemble.ExtraTreesRegressor** An extra-trees regressor.

Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

### apply

Return the index of the leaf that each sample is predicted as.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided a sparse `csr_matrix`.
- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **X_leaves** [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

### cost_complexity_pruning_path

Compute the pruning path during Minimal Cost-Complexity Pruning.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path  [Bunch] Dictionary-like object, with the following attributes.

ccp_alphas  [ndarray] Effective alphas of subtree during pruning.

impurities  [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path  (X, check_input=True)

Return the decision path in the tree.

New in version 0.18.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator  [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns

feature_importances_  [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).

fit  (X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')

Build a decision tree classifier from the training set (X, y).

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.
**check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**X_idx_sorted** [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in v0.26.

Deprecated since version 0.24.

**Returns**

self [DecisionTreeClassifier] Fitted estimator.

**get_depth**()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**Returns**

self.tree_.max_depth [int] The maximum depth of the tree.

**get_n_leaves**()

Return the number of leaves of the decision tree.

**Returns**

self.tree_.n_leaves [int] Number of leaves.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**predict**(X, check_input=True)

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

**Parameters**

X [array-like, sparse matrix] of shape (n_samples, n_features) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

**predict_log_proba**(X)

Predict class log-probabilities of the input samples X.

**Parameters**
X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba (X, check_input=True)
Predict class probabilities of the input samples X.

The predicted class probability is the fraction of samples of the same class in a leaf.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
7.37.4 sklearn.tree.ExtraTreeRegressor

class sklearn.tree.ExtraTreeRegressor(**kwargs)
    An extremely randomized tree regressor.

    Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the max_features randomly selected features and the best split among those is chosen. When max_features is set 1, this amounts to building a totally random decision tree.

    Warning: Extra-trees should only be used within ensemble methods.

    Read more in the User Guide.

    Parameters

    criterion ['mse', 'friedman_mse', 'mae'], default='mse'] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion, and "mae" for the mean absolute error.

    New in version 0.18: Mean Absolute Error (MAE) criterion.

    splitter ['random', 'best'], default='random'] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

    max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

    min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:
    • If int, then consider min_samples_split as the minimum number.
    • If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

    Changed in version 0.18: Added float values for fractions.

    min_samples_leaf [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
    • If int, then consider min_samples_leaf as the minimum number.
    • If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

    Changed in version 0.18: Added float values for fractions.

    min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

    max_features [int, float, ['auto', 'sqrt', 'log2'] or None, default='auto'] The number of features to consider when looking for the best split:
    • If int, then consider max_features features at each split.
    • If float, then max_features is a fraction and int(max_features * n_features) features are considered at each split.
• If “auto”, then max_features=n_features.
• If “sqrt”, then max_features=sqrt(n_features).
• If “log2”, then max_features=log2(n_features).
• If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

random_state [int, RandomState instance or None, default=None] Used to pick randomly the max_features used at each split. See Glossary for details.

min_impurity_decrease [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity} \right)
\]

where N is the total number of samples, N_t is the number of samples at the current node, N_{t,L} is the number of samples in the left child, and N_{t,R} is the number of samples in the right child.

N, N_t, N_{t,R} and N_{t,L} all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

min_impurity_split [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.

max_leaf_nodes [int, default=None] Grow a tree with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

ccp_alpha [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

Attributes

max_features_ [int] The inferred value of max_features.

n_features_ [int] The number of features when fit is performed.

feature_importances_ [ndarray of shape (n_features,)] Return the feature importances.

n_outputs_ [int] The number of outputs when fit is performed.

tree_ [Tree instance] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and Understanding the decision tree structure for basic usage of these attributes.

See also:

7.37. sklearn.tree: Decision Trees
ExtraTreeClassifier An extremely randomized tree classifier.

Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

Examples

```python
>>> from sklearn.datasets import load_diabetes
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.tree import ExtraTreeRegressor

>>> X, y = load_diabetes(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(...
...     X, y, random_state=0)
>>> extra_tree = ExtraTreeRegressor(random_state=0)
>>> reg = BaggingRegressor(extra_tree, random_state=0).fit(...
...     X_train, y_train)
>>> reg.score(X_test, y_test)
0.33...
```

apply (X, check_input=True)  
Return the index of the leaf that each sample is predicted as.
New in version 0.17.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

X_leaves  [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

cost_complexity_pruning_path  (X, y, sample_weight=None)
Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path  [Bunch] Dictionary-like object, with the following attributes.

ccp_alphas  [ndarray] Effective alphas of subtree during pruning.

impurities  [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path  (X, check_input=True)
Return the decision path in the tree.

New in version 0.18.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator  [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.
property feature_importances_
  Return the feature importances.

  The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that
  feature. It is also known as the Gini importance.

  Warning: impurity-based feature importances can be misleading for high cardinality features (many unique
  values). See sklearn.inspection.permutation_importance as an alternative.

  Returns

  feature_importances_  [ndarray of shape (n_features,)] Normalized total reduction of crite-
  ria by feature (Gini importance).

fit (X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')
  Build a decision tree regressor from the training set (X, y).

  Parameters

  X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.
      Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided
      to a sparse csc_matrix.

  y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (real num-
      bers). Use dtype=np.float64 and order='C' for maximum efficiency.

  sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None,
      then samples are equally weighted. Splits that would create child nodes with net zero or
      negative weight are ignored while searching for a split in each node.

  check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this
      parameter unless you know what you do.

  X_idx_sorted  [deprecated, default="deprecated"] This parameter is deprecated and has no
      effect. It will be removed in v0.26.

      Deprecated since version 0.24.

  Returns

  self  [DecisionTreeRegressor] Fitted estimator.

get_depth ()
  Return the depth of the decision tree.

  The depth of a tree is the maximum distance between the root and any leaf.

  Returns

  self.tree_.max_depth  [int] The maximum depth of the tree.

get_n_leaves ()
  Return the number of leaves of the decision tree.

  Returns

  self.tree_.n_leaves  [int] Number of leaves.

get_params (deep=True)
  Get parameters for this estimator.

  Parameters

  deep  [bool, default=True] If True, will return the parameters for this estimator and contained
      subobjects that are estimators.
Returns

params [dict] Parameter names mapped to their values.

predict (X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{\text{true}} - y_{\text{pred}})^2).\text{sum()}$ and $v$ is the total sum of squares $((y_{\text{true}} - y_{\text{true}}.\text{mean()})^2).\text{sum()}$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

7.37. sklearn.tree: Decision Trees
**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

```
.. py:method:: tree.export_graphviz(decision_tree[, ...])
   Export a decision tree in DOT format.
```

```
.. py:method:: tree.export_text(decision_tree, *[...])
   Build a text report showing the rules of a decision tree.
```

7.37.5 sklearn.tree.export_graphviz

```
sklearn.tree.export_graphviz(decision_tree, out_file=None, *
   feature_names=None, class_names=None, label='all', filled=False,
   leaves_parallel=False, impurity=True, node_ids=False,
   proportion=False, rotate=False, rounded=False, special_characters=False,
   precision=3)
```

Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into `out_file`.

Once exported, graphical renderings can be generated using, for example:

```
$ dot -Tps tree.dot -o tree.ps (PostScript format)
$ dot -Tpng tree.dot -o tree.png (PNG format)
```

The sample counts that are shown are weighted with any sample_weights that might be present.

Read more in the User Guide.

Parameters

- **decision_tree** [decision tree classifier] The decision tree to be exported to GraphViz.
- **out_file** [object or str, default=None] Handle or name of the output file. If None, the result is returned as a string.

  Changed in version 0.20: Default of out_file changed from “tree.dot” to None.

- **max_depth** [int, default=None] The maximum depth of the representation. If None, the tree is fully generated.

- **feature_names** [list of str, default=None] Names of each of the features. If None generic names will be used (“feature_0”, “feature_1”, …).

- **class_names** [list of str or bool, default=None] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.

- **label** [‘all’, ‘root’, ‘none’], default=’all’) Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.

- **filled** [bool, default=False] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

- **leaves_parallel** [bool, default=False] When set to True, draw all leaf nodes at the bottom of the tree.

- **impurity** [bool, default=True] When set to True, show the impurity at each node.

- **node_ids** [bool, default=False] When set to True, show the ID number on each node.
**proportion** [bool, default=False] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.

**rotate** [bool, default=False] When set to True, orient tree left to right rather than top-down.

**rounded** [bool, default=False] When set to True, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

**special_characters** [bool, default=False] When set to False, ignore special characters for PostScript compatibility.

**precision** [int, default=3] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

**Returns**

**dot_data** [string] String representation of the input tree in GraphViz dot format. Only returned if out_file is None.

New in version 0.18.

**Examples**

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree

>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()

>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf)
'digraph Tree {...
```

7.37.6 sklearn.tree.export_text

**sklearn.tree.export_text**(decision_tree, *, feature_names=None, max_depth=10, spacing=3, decimals=2, show_weights=False)

Build a text report showing the rules of a decision tree.

Note that backwards compatibility may not be supported.

**Parameters**

- **decision_tree** [object] The decision tree estimator to be exported. It can be an instance of DecisionTreeClassifier or DecisionTreeRegressor.
- **feature_names** [list of str, default=None] A list of length n_features containing the feature names. If None generic names will be used (“feature_0”, “feature_1”, …).
- **max_depth** [int, default=10] Only the first max_depth levels of the tree are exported. Truncated branches will be marked with “…”.
- **spacing** [int, default=3] Number of spaces between edges. The higher it is, the wider the result.
- **decimals** [int, default=2] Number of decimal digits to display.
- **show_weights** [bool, default=False] If true the classification weights will be exported on each leaf. The classification weights are the number of samples each class.

**Returns**
**report** [string] Text summary of all the rules in the decision tree.

### Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.tree import DecisionTreeClassifier
>>> from sklearn.tree import export_text

>>> iris = load_iris()
>>> X = iris['data']
>>> y = iris['target']
>>> decision_tree = DecisionTreeClassifier(random_state=0, max_depth=2)
>>> decision_tree = decision_tree.fit(X, y)
>>> r = export_text(decision_tree, feature_names=iris['feature_names'])
>>> print(r)

|--- petal width (cm) <= 0.80
| |--- class: 0
|--- petal width (cm) > 0.80
| |--- petal width (cm) <= 1.75
| | |--- class: 1
| |--- petal width (cm) > 1.75
| | |--- class: 2
```

### 7.37.7 Plotting

**tree.plot_tree**

```
>>> tree.plot_tree(decision_tree, *[, ...])
```

Plot a decision tree.

**sklearn.tree.plot_tree**

```
sklearn.tree.plot_tree(decision_tree, *, max_depth=None, feature_names=None, class_names=None, label='all', filled=False, impurity=True, node_ids=False, proportion=False, rotate='deprecated', rounded=False, precision=3, ax=None, fontsize=None)
```

Plot a decision tree.

The sample counts that are shown are weighted with any sample_weights that might be present.

The visualization is fit automatically to the size of the axis. Use the **figsize** or **dpi** arguments of **plt.figure** to control the size of the rendering.

Read more in the **User Guide**.

New in version 0.21.

**Parameters**

- **decision_tree** [decision tree regressor or classifier] The decision tree to be plotted.
- **max_depth** [int, default=None] The maximum depth of the representation. If None, the tree is fully generated.
- **feature_names** [list of strings, default=None] Names of each of the features. If None, generic names will be used ("X[0]", "X[1]", ...).
- **class_names** [list of str or bool, default=None] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.
label \[\{'all', 'root', 'none'\}, \text{default}='all'\] Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.

filled \[\text{bool, default}=\text{False}\] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

impurity \[\text{bool, default}=\text{True}\] When set to True, show the impurity at each node.

node_ids \[\text{bool, default}=\text{False}\] When set to True, show the ID number on each node.

proportion \[\text{bool, default}=\text{False}\] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.

rotate \[\text{bool, default}=\text{False}\] This parameter has no effect on the matplotlib tree visualisation and it is kept here for backward compatibility.

Deprecated since version 0.23: rotate is deprecated in 0.23 and will be removed in 0.25.

rounded \[\text{bool, default}=\text{False}\] When set to True, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

precision \[\text{int, default}=3\] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

ax \[\text{matplotlib axis, default}=\text{None}\] Axes to plot to. If None, use current axis. Any previous content is cleared.

fontsize \[\text{int, default}=\text{None}\] Size of text font. If None, determined automatically to fit figure.

Returns

annotations \[\text{list of artists}\] List containing the artists for the annotation boxes making up the tree.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree

>>> clf = tree.DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()

>>> clf = clf.fit(iris.data, iris.target)
>>> tree.plot_tree(clf)
```

Examples using sklearn.tree.plot_tree

- Plot the decision surface of a decision tree on the iris dataset
- Understanding the decision tree structure
# 7.38 `sklearn.utils`: Utilities

The `sklearn.utils` module includes various utilities.

**Developer guide:** See the Utilities for Developers page for further details.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>utils.arrayfuncs.min_pos</code></td>
<td>Find the minimum value of an array over positive values</td>
</tr>
<tr>
<td><code>utils.as_float_array(X, *, copy, ...)</code></td>
<td>Converts an array-like to an array of floats.</td>
</tr>
<tr>
<td><code>utils.assert_all_finite(X, *, allow_nan)</code></td>
<td>Throw a ValueError if X contains NaN or infinity.</td>
</tr>
<tr>
<td><code>utils.Bunch(**kwargs)</code></td>
<td>Container object exposing keys as attributes.</td>
</tr>
<tr>
<td><code>utils.check_X_y(X, y[, accept_sparse, ...])</code></td>
<td>Input validation for standard estimators.</td>
</tr>
<tr>
<td><code>utils.check_array(array[, accept_sparse, ...])</code></td>
<td>Input validation on an array, list, sparse matrix or similar.</td>

</tr>
<tr>
<td><code>utils.extmath.randomized_range_finder(A, *, ...)</code></td>
<td>Computes an orthonormal matrix whose range approximates the range of A.</td>
</tr>
<tr>
<td><code>utils.extmath.randomized_svd(M, n_components, *)</code></td>
<td>Computes a truncated randomized SVD.</td>
</tr>
<tr>
<td><code>utils.extmath.fast_logdet(A)</code></td>
<td>Compute log(det(A)) for A symmetric.</td>
</tr>
<tr>
<td><code>utils.extmath.density(w, **kwargs)</code></td>
<td>Compute density of a sparse vector.</td>
</tr>
<tr>
<td><code>utils.extmath.weighted_mode(a, w, *, axis)</code></td>
<td>Returns an array of the weighted modal (most common) value in a.</td>
</tr>
<tr>
<td><code>utils.gen_even_slices(n, n_packs, *, [n_samples])</code></td>
<td>Generator to create n_packs slices going up to n.</td>
</tr>
<tr>
<td><code>utils.graph.single_source_shortest_path</code></td>
<td>Return the shortest path length from source to all reachable nodes.</td>
</tr>
<tr>
<td><code>utils.graph_shortest_path.graph_shortest_path</code></td>
<td>Perform a shortest-path graph search on a positive directed or undirected graph.</td>
</tr>
<tr>
<td><code>utils.indexable(*iterables)</code></td>
<td>Make arrays indexable for cross-validation.</td>
</tr>
<tr>
<td><code>utils.metaestimators.if_delegate_has_method(...)</code></td>
<td>Create a decorator for methods that are delegated to a sub-estimator.</td>
</tr>
<tr>
<td><code>utils.multiclass.type_of_target(y)</code></td>
<td>Determine the type of data indicated by the target.</td>
</tr>
<tr>
<td><code>utils.multiclass.is_multilabel(y)</code></td>
<td>Check if y is in a multilabel format.</td>
</tr>
<tr>
<td><code>utils.multiclass.unique_labels(*ys)</code></td>
<td>Extract an ordered array of unique labels.</td>
</tr>
<tr>
<td><code>utils.murmurhash3_32</code></td>
<td>Compute the 32bit murmurhash3 of key at seed.</td>
</tr>
<tr>

#### 7.38.1 sklearn.utils.arrayfuncs.min_pos

`sklearn.utils.arrayfuncs.min_pos()`  
Find the minimum value of an array over positive values  
Returns a huge value if none of the values are positive
7.38.2 sklearn.utils.as_float_array

sklearn.utils.as_float_array(X, *, copy=True, force_all_finite=True)

Converts an array-like to an array of floats.

The new dtype will be np.float32 or np.float64, depending on the original type. The function can create a copy or modify the argument depending on the argument copy.

Parameters

X [{array-like, sparse matrix}]
copy [bool, default=True] If True, a copy of X will be created. If False, a copy may still be returned if X’s dtype is not a floating point type.

force_all_finite [bool or ‘allow-nan’, default=True] Whether to raise an error on np.inf, np.nan, pd.NA in X. The possibilities are:

• True: Force all values of X to be finite.
• False: accepts np.inf, np.nan, pd.NA in X.
• ‘allow-nan’: accepts only np.nan and pd.NA values in X. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.
Changed in version 0.23: Accepts pd.NA and converts it into np.nan

Returns

XT [{ndarray, sparse matrix}] An array of type float.

7.38.3 sklearn.utils.assert_all_finite

sklearn.utils.assert_all_finite(X, *, allow_nan=False)

Throw a ValueError if X contains NaN or infinity.

Parameters

X [{ndarray, sparse matrix}]

allow_nan [bool, default=False]

7.38.4 sklearn.utils.Bunch

sklearn.utils.Bunch(**kwargs)

Container object exposing keys as attributes.

Bunch objects are sometimes used as an output for functions and methods. They extend dictionaries by enabling values to be accessed by key, bunch["value_key"], or by an attribute, bunch.value_key.
Examples

```python
>>> b = Bunch(a=1, b=2)
>>> b['b']
2
>>> b.b
2
>>> b.a = 3
>>> b['a']
3
>>> b.c = 6
>>> b['c']
6
```

Examples using `sklearn.utils.Bunch`

- Species distribution modeling

7.38.5 `sklearn.utils.check_X_y`

`sklearn.utils.check_X_y` (X, y, accept_sparse=False, *, accept_large_sparse=True, dtype='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, multi_output=False, ensure_min_samples=1, ensure_min_features=1, y_numeric=False, estimator=None)

Input validation for standard estimators.

Checks X and y for consistent length, enforces X to be 2D and y 1D. By default, X is checked to be non-empty and containing only finite values. Standard input checks are also applied to y, such as checking that y does not have np.nan or np.inf targets. For multi-label y, set multi_output=True to allow 2D and sparse y. If the dtype of X is object, attempt converting to float, raising on failure.

Parameters

X [{ndarray, list, sparse matrix}] Input data.

y [{ndarray, list, sparse matrix}] Labels.

accept_sparse [str, bool or list of str, default=False] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

accept_large_sparse [bool, default=True] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept_sparse, accept_large_sparse will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

dtype [‘numeric’, type, list of type or None, default=’numeric’] Data type of result. If None, the dtype of the input is preserved. If “numeric”, dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order [{‘F’, ‘C’}, default=None] Whether an array will be forced to be fortran or c-style.

copy [bool, default=False] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.
force_all_finite [bool or ‘allow-nan’, default=True] Whether to raise an error on np.inf, np.nan, pd.NA in X. This parameter does not influence whether y can have np.inf, np.nan, pd.NA values. The possibilities are:

- True: Force all values of X to be finite.
- False: accepts np.inf, np.nan, pd.NA in X.
- ‘allow-nan’: accepts only np.nan or pd.NA values in X. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string ‘allow-nan’.
Changed in version 0.23: Accepts pd.NA and converts it into np.nan

ensure_2d [bool, default=True] Whether to raise a value error if X is not 2D.

allow_nd [bool, default=False] Whether to allow X.ndim > 2.

multi_output [bool, default=False] Whether to allow 2D y (array or sparse matrix). If false, y will be validated as a vector. y cannot have np.nan or np.inf values if multi_output=True.

ensure_min_samples [int, default=1] Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

ensure_min_features [int, default=1] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.

y_numeric [bool, default=False] Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to float64. Should only be used for regression algorithms.

estimator [str or estimator instance, default=None] If passed, include the name of the estimator in warning messages.

Returns

X_converted [object] The converted and validated X.

y_converted [object] The converted and validated y.

7.38.6 sklearn.utils.check_array

sklearn.utils.check_array(array, accept_sparse=False, *, accept_large_sparse=True, dtype=’numeric’, order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, ensure_min_samples=1, ensure_min_features=1, estimator=None)

Input validation on an array, list, sparse matrix or similar.

By default, the input is checked to be a non-empty 2D array containing only finite values. If the dtype of the array is object, attempt converting to float, raising on failure.

Parameters

array [object] Input object to check / convert.

accept_sparse [str, bool or list/tuple of str, default=False] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.
accept_large_sparse [bool, default=True] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept_sparse, accept_large_sparse=False will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

dtype ['numeric', type, list of type or None, default='numeric'] Data type of result. If None, the dtype of the input is preserved. If “numeric”, dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order [{‘F’, ‘C’} or None, default=None] Whether an array will be forced to be fortran or c-style. When order is None (default), then if copy=False, nothing is ensured about the memory layout of the output array; otherwise (copy=True) the memory layout of the returned array is kept as close as possible to the original array.

copy [bool, default=False] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite [bool or ‘allow-nan’, default=True] Whether to raise an error on np.inf, np.nan, pd.NA in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accepts np.inf, np.nan, pd.NA in array.
- ‘allow-nan’: accepts only np.nan and pd.NA values in array. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan

ensure_2d [bool, default=True] Whether to raise a value error if array is not 2D.

allow_nd [bool, default=False] Whether to allow array.ndim > 2.

ensure_min_samples [int, default=1] Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.

ensure_min_features [int, default=1] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input data has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.

estimator [str or estimator instance, default=None] If passed, include the name of the estimator in warning messages.

Returns

array_converted [object] The converted and validated array.

7.38.7 sklearn.utils.check_scalar

sklearn.utils.check_scalar(x, name, target_type, *, min_val=None, max_val=None)
Validate scalar parameters type and value.

Parameters

x [object] The scalar parameter to validate.

name [str] The name of the parameter to be printed in error messages.

target_type [type or tuple] Acceptable data types for the parameter.
**min_val** [float or int, default=None] The minimum valid value the parameter can take. If None (default) it is implied that the parameter does not have a lower bound.

**max_val** [float or int, default=None] The maximum valid value the parameter can take. If None (default) it is implied that the parameter does not have an upper bound.

**Raises**

- **TypeError** If the parameter’s type does not match the desired type.
- **ValueError** If the parameter’s value violates the given bounds.

### 7.38.8 sklearn.utils.check_consistent_length

**sklearn.utils.check_consistent_length (*arrays)**

Check that all arrays have consistent first dimensions.

Checks whether all objects in arrays have the same shape or length.

**Parameters**

- *arrays [list or tuple of input objects.] Objects that will be checked for consistent length.

### 7.38.9 sklearn.utils.check_random_state

**sklearn.utils.check_random_state (seed)**

Turn seed into a np.random.RandomState instance

**Parameters**

- seed [None, int or instance of RandomState] If seed is None, return the RandomState singleton used by np.random. If seed is an int, return a new RandomState instance seeded with seed. If seed is already a RandomState instance, return it. Otherwise raise ValueError.

#### Examples using sklearn.utils.check_random_state

- *Empirical evaluation of the impact of k-means initialization*
- *MNIST classification using multinomial logistic + L1*
- *Manifold Learning methods on a severed sphere*
- *Isotonic Regression*
- *Face completion with a multi-output estimators*
- *Scaling the regularization parameter for SVCs*

### 7.38.10 sklearn.utils.class_weight.compute_class_weight

**sklearn.utils.class_weight.compute_class_weight (class_weight, *, classes, y)**

Estimate class weights for unbalanced datasets.

**Parameters**

- **class_weight [dict, ‘balanced’ or None] If ‘balanced’, class weights will be given by n_samples / (n_classes * np.bincount(y)). If a dictionary is given, keys are classes and values are corresponding class weights. If None is given, the class weights will be uniform.**
classes [ndarray] Array of the classes occurring in the data, as given by np.unique(y_org) with y_org the original class labels.

y [array-like of shape (n_samples,)] Array of original class labels per sample.

Returns

class_weight_vect [ndarray of shape (n_classes,)] Array with class_weight_vect[i] the weight for i-th class.

References

The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

7.38.11 sklearn.utils.class_weight.compute_sample_weight

sklearn.utils.class_weight.compute_sample_weight(class_weight, y, *, indices=None)
Estimate sample weights by class for unbalanced datasets.

Parameters

class_weight [dict, list of dicts, “balanced”, or None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data: n_samples / (n_classes * np.bincount(y)).

For multi-output, the weights of each column of y will be multiplied.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Array of original class labels per sample.

indices [array-like of shape (n_subsample,), default=None] Array of indices to be used in a subsample. Can be of length less than n_samples in the case of a subsample, or equal to n_samples in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only “balanced” is supported for class_weight if this is provided.

Returns

sample_weight_vect [ndarray of shape (n_samples,)] Array with sample weights as applied to the original y.
7.38.12 sklearn.utils.deprecated

sklearn.utils.deprecated(extra="")
Decorator to mark a function or class as deprecated.

Issue a warning when the function is called/the class is instantiated and adds a warning to the docstring.

The optional extra argument will be appended to the deprecation message and the docstring. Note: to use this
with the default value for extra, put in an empty of parentheses:

```python
>>> from sklearn.utils import deprecated
>>> deprecated()
<sklearn.utils.deprecation.deprecated object at ...>
```

```python
>>> @deprecated()
... def some_function():
...     pass
```

Parameters

extra [str, default=""] To be added to the deprecation messages.

7.38.13 sklearn.utils.estimator_checks.check_estimator

sklearn.utils.estimator_checks.check_estimator(Estimator, generate_only=False, strict_mode=True)

Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc, making sure that the estimator
complies with scikit-learn conventions as detailed in Rolling your own estimator. Additional tests for
classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the correspond-
ing mixin from sklearn.base.

Setting generate_only=True returns a generator that yields (estimator, check) tuples where the check
can be called independently from each other, i.e. check(estimator). This allows all checks to be run
independently and report the checks that are failing.

scikit-learn provides a pytest specific decorator, parametrize_with_checks, making it easier to test mul-
tiple estimators.

Parameters

Estimator [estimator object] Estimator instance to check.

Changed in version 0.24: Passing a class was deprecated in version 0.23, and support for
classes was removed in 0.24.

generate_only [bool, default=False] When False, checks are evaluated when
check_estimator is called. When True, check_estimator returns a generator
that yields (estimator, check) tuples. The check is run by calling check(estimator).

New in version 0.22.

strict_mode [bool, default=True] If True, the full check suite is run. If False, only the non-strict
part of the check suite is run.

In non-strict mode, some checks will be easier to pass: e.g., they will only make sure an
error is raised instead of also checking the full error message. Some checks are consid-
ered completely strict, in which case they are treated as if they were in the estimators’
_xfails Checks tag: they will be ignored with a warning. See Estimator Tags for
more info on the `_xfails_check` tag. The set of strict checks is in sklearn.utils.estimator_checks._FULLY_STRICT_CHECKS.

New in version 0.24.

Returns

- `checks_generator` [generator] Generator that yields (estimator, check) tuples. Returned when `generate_only=True`.

### 7.38.14 sklearn.utils.estimator_checks.parametrize_with_checks

`sklearn.utils.estimator_checks.parametrize_with_checks(estimators, strict_mode=True)`

Pytest specific decorator for parametrizing estimator checks.

The id of each check is set to be a pprint version of the estimator and the name of the check with its keyword arguments. This allows to use pytest -k to specify which tests to run:

```bash
pytest test_check_estimators.py -k check_estimators_fit_returns_self
```

Parameters

- `estimators` [list of estimators instances] Estimators to generated checks for.
  
  Changed in version 0.24: Passing a class was deprecated in version 0.23, and support for classes was removed in 0.24. Pass an instance instead.

- `strict_mode` [bool, default=True] If True, the full check suite is run. If False, only the non-strict part of the check suite is run.

  In non-strict mode, some checks will be easier to pass: e.g., they will only make sure an error is raised instead of also checking the full error message. Some checks are considered completely strict, in which case they are treated as if they were in the estimators’ `_xfails_checks` tag: they will be marked as `xfail` for pytest. See Estimator Tags for more info on the `_xfails_check` tag. The set of strict checks is in sklearn.utils.estimator_checks._FULLY_STRICT_CHECKS.

New in version 0.24.

Returns

- `decorator` [pytest.mark.parametrize]

Examples

```python
>>> from sklearn.utils.estimator_checks import parametrize_with_checks
def test_sklearn_compatible_estimator(estimator, check):
    check(estimator)

>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.tree import DecisionTreeRegressor

>>> @parametrize_with_checks([LogisticRegression(), DecisionTreeRegressor()])
... def test_sklearn_compatible_estimator(estimator, check):
...     check(estimator)
```
Examples using `sklearn.utils.estimator_checks.parametrize_with_checks`

- Release Highlights for scikit-learn 0.22

### 7.38.15 sklearn.utils.estimator_html_repr

**sklearn.utils.estimator_html_repr(estimator)**

Build a HTML representation of an estimator.

Read more in the *User Guide*.

**Parameters**

- **estimator**: estimator object
  The estimator to visualize.

**Returns**

- **html**: str
  HTML representation of estimator.

### 7.38.16 sklearn.utils.extmath.safe_sparse_dot

**sklearn.utils.extmath.safe_sparse_dot(a, b, *, dense_output=False)**

Dot product that handle the sparse matrix case correctly.

**Parameters**

- **a** ([ndarray, sparse matrix])
- **b** ([ndarray, sparse matrix])
- **dense_output** [bool, default=False] When False, a and b both being sparse will yield sparse output. When True, output will always be a dense array.

**Returns**

- **dot_product** ([ndarray, sparse matrix]) Sparse if a and b are sparse and dense_output=False.

### 7.38.17 sklearn.utils.extmath.randomized_range_finder

**sklearn.utils.extmath.randomized_range_finder(A, *, size, n_iter,**

```
    power_iteration_normalizer='auto',
    random_state=None)
```

Computes an orthonormal matrix whose range approximates the range of A.

**Parameters**

- **A** [2D array] The input data matrix.
- **size** [int] Size of the return array.
- **n_iter** [int] Number of power iterations used to stabilize the result.
- **power_iteration_normalizer** [‘auto’, ‘QR’, ‘LU’, ‘none’], default=’auto’] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), ‘none’ (the fastest but numerically unstable when n_iter is large, e.g. typically 5 or larger), or ‘LU’ factorization (numerically stable but can lose slightly in accuracy). The ‘auto’ mode applies no normalization if n_iter <= 2 and switches to LU otherwise.

New in version 0.18.
**random_state** [int, RandomState instance or None, default=None] The seed of the pseudo random number generator to use when shuffling the data, i.e. getting the random vectors to initialize the algorithm. Pass an int for reproducible results across multiple function calls. See Glossary.

**Returns**

Q [ndarray] A (size x size) projection matrix, the range of which approximates well the range of the input matrix A.

**Notes**

An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

### 7.38.18 sklearn.utils.extmath.randomized_svd

**sklearn.utils.extmath.randomized_svd** *(M, n_components, *, n_oversamples=10, n_iter='auto', power_iteration_normalizer='auto', transpose='auto', flip_sign=True, random_state=0)*

Computes a truncated randomized SVD.

**Parameters**

- **M** [{ndarray, sparse matrix}] Matrix to decompose.
- **n_components** [int] Number of singular values and vectors to extract.
- **n_oversamples** [int, default=10] Additional number of random vectors to sample the range of M so as to ensure proper conditioning. The total number of random vectors used to find the range of *M* is *n_components* + *n_oversamples*. Smaller number can improve speed but can negatively impact the quality of approximation of singular vectors and singular values.
- **n_iter** [int or ‘auto’, default='auto'] Number of power iterations. It can be used to deal with very noisy problems. When ‘auto’, it is set to 4, unless *n_components* is small (< .1 * min(X.shape)) *n_iter* in which case is set to 7. This improves precision with few components.
  
  Changed in version 0.18.
- **power_iteration_normalizer** [‘auto’, ‘QR’, ‘LU’, ‘none’], default=’auto’] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), ‘none’ (the fastest but numerically unstable when *n_iter* is large, e.g. typically 5 or larger), or ‘LU’ factorization (numerically stable but can lose slightly in accuracy). The ‘auto’ mode applies no normalization if *n_iter* <= 2 and switches to LU otherwise.
  
  New in version 0.18.
- **transpose** [bool or ‘auto’, default=’auto’] Whether the algorithm should be applied to *M.T* instead of *M*. The result should approximately be the same. The ‘auto’ mode will trigger the transposition if M.shape[1] > M.shape[0] since this implementation of randomized SVD tend to be a little faster in that case.
  
  Changed in version 0.18.
- **flip_sign** [bool, default=True] The output of a singular value decomposition is only unique up to a permutation of the signs of the singular vectors. If flip_sign is set to True, the sign
ambiguity is resolved by making the largest loadings for each component in the left singular vectors positive.

**random_state** [int, RandomState instance or None, default=0] The seed of the pseudo random number generator to use when shuffling the data, i.e. getting the random vectors to initialize the algorithm. Pass an int for reproducible results across multiple function calls. See *Glossary.*

**Notes**

This algorithm finds a (usually very good) approximate truncated singular value decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components. In order to obtain further speed up, *n_iter* can be set <=2 (at the cost of loss of precision).

**References**

- A randomized algorithm for the decomposition of matrices Per-Gunnar Martinsson, Vladimir Rokhlin and Mark Tygert
- An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

### 7.38.19 sklearn.utils.extmath.fast_logdet

**sklearn.utils.extmath.fast_logdet**(A)

Compute log(det(A)) for A symmetric.

Equivalent to : np.log(nl.det(A)) but more robust. It returns -Inf if det(A) is non positive or is not defined.

**Parameters**

### 7.38.20 sklearn.utils.extmath.density

**sklearn.utils.extmath.density**(w, **kwargs)

Compute density of a sparse vector.

**Parameters**

w [array-like] The sparse vector.

**Returns**

float The density of w, between 0 and 1.
Examples using `sklearn.utils.extmath.density`

- Classification of text documents using sparse features

### 7.38.21 sklearn.utils.extmath.weighted_mode

`sklearn.utils.extmath.weighted_mode(a, w, *, axis=0)`

Returns an array of the weighted modal (most common) value in `a`.

If there is more than one such value, only the first is returned. The bin-count for the modal bins is also returned.

This is an extension of the algorithm in `scipy.stats.mode`.

**Parameters**
- `a` [array-like] n-dimensional array of which to find mode(s).
- `w` [array-like] n-dimensional array of weights for each value.
- `axis` [int, default=0] Axis along which to operate. Default is 0, i.e. the first axis.

**Returns**
- `vals` [ndarray] Array of modal values.
- `score` [ndarray] Array of weighted counts for each mode.

**See also:**
- `scipy.stats.mode`

**Examples**

```python
>>> from sklearn.utils.extmath import weighted_mode
>>> x = [4, 1, 4, 2, 4, 2]
>>> weights = [1, 1, 1, 1, 1, 1]
>>> weighted_mode(x, weights)
(array([4.]), array([3.]))
```

The value 4 appears three times: with uniform weights, the result is simply the mode of the distribution.

```python
>>> weights = [1, 3, 0.5, 1.5, 1, 2]  # deweight the 4's
>>> weighted_mode(x, weights)
(array([2.]), array([3.5]))
```

The value 2 has the highest score: it appears twice with weights of 1.5 and 2: the sum of these is 3.5.

### 7.38.22 sklearn.utils.gen_even_slices

`sklearn.utils.gen_even_slices(n, n_packs, *, n_samples=None)`

Generator to create `n_packs` slices going up to `n`.

**Parameters**
- `n` [int]
- `n_packs` [int] Number of slices to generate.
n_samples [int, default=None] Number of samples. Pass n_samples when the slices are to be used for sparse matrix indexing; slicing off-the-end raises an exception, while it works for NumPy arrays.

Yields

slice

Examples

```python
>>> from sklearn.utils import gen_even_slices
>>> list(gen_even_slices(10, 1))
[slice(0, 10, None)]
>>> list(gen_even_slices(10, 10))
[slice(0, 1, None), slice(1, 2, None), ..., slice(9, 10, None)]
>>> list(gen_even_slices(10, 5))
[slice(0, 2, None), slice(2, 4, None), ..., slice(8, 10, None)]
>>> list(gen_even_slices(10, 3))
[slice(0, 4, None), slice(4, 7, None), slice(7, 10, None)]
```

Examples using sklearn.utils.gen_even_slices

- Poisson regression and non-normal loss

7.38.23 sklearn.utils.graph.single_source_shortest_path_length

sklearn.utils.graph.single_source_shortest_path_length(graph, source, *, cutoff=None)

Return the shortest path length from source to all reachable nodes.

Returns a dictionary of shortest path lengths keyed by target.

Parameters

- graph [{sparse matrix, ndarray} of shape (n, n)] Adjacency matrix of the graph. Sparse matrix of format LIL is preferred.
- source [int] Starting node for path.
- cutoff [int, default=None] Depth to stop the search - only paths of length <= cutoff are returned.

Examples

```python
>>> from sklearn.utils.graph import single_source_shortest_path_length
>>> import numpy as np

>>> graph = np.array([[0, 1, 0, 0],
...                    [1, 0, 1, 0],
...                    [0, 1, 0, 1],
...                    [0, 0, 1, 0]])

>>> list(sorted(single_source_shortest_path_length(graph, 0).items()))
[(0, 0), (1, 1), (2, 2), (3, 3)]

>>> graph = np.ones((6, 6))

>>> list(sorted(single_source_shortest_path_length(graph, 2).items()))
[(0, 1), (1, 1), (2, 0), (3, 1), (4, 1), (5, 1)]
```
7.38.24 sklearn.utils.graph_shortest_path.graph_shortest_path

sklearn.utils.graph_shortest_path.graph_shortest_path()
Perform a shortest-path graph search on a positive directed or undirected graph.

Parameters

- **dist_matrix** [arraylike or sparse matrix, shape = (N,N)] Array of positive distances. If vertex i is connected to vertex j, then dist_matrix[i,j] gives the distance between the vertices. If vertex i is not connected to vertex j, then dist_matrix[i,j] = 0
- **directed** [boolean] if True, then find the shortest path on a directed graph: only progress from a point to its neighbors, not the other way around. if False, then find the shortest path on an undirected graph: the algorithm can progress from a point to its neighbors and vice versa.
- **method** [string ['auto'|'FW'|'D']] method to use. Options are 'auto' : attempt to choose the best method for the current problem 'FW' : Floyd-Warshall algorithm. O[N^3] 'D' : Dijkstra’s algorithm with Fibonacci stacks. O((k+log(N))N^2)

Returns

- **G** [np.ndarray, float, shape = [N,N]] G[i,j] gives the shortest distance from point i to point j along the graph.

Notes

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if dist_matrix[i,j] and dist_matrix[j,i] are not equal and both are nonzero, method=‘D’ will not necessarily yield the correct result.

Also, these routines have not been tested for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms.

7.38.25 sklearn.utils.indexable

sklearn.utils.indexable(*iterables)
Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-interable objects to arrays.

Parameters

- **iterables** [[lists, dataframes, ndarrays, sparse matrices]] List of objects to ensure sliceability.

7.38.26 sklearn.utils.metaestimators.if_delegate_has_method

sklearn.utils.metaestimators.if_delegate_has_method(delegate)
Create a decorator for methods that are delegated to a sub-estimator

This enables ducktyping by hasattr returning True according to the sub-estimator.

Parameters

- **delegate** [string, list of strings or tuple of strings] Name of the sub-estimator that can be accessed as an attribute of the base object. If a list or a tuple of names are provided, the first sub-estimator that is an attribute of the base object will be used.
Examples using sklearn.utils.metaestimators.if_delegate_has_method

• Inductive Clustering

7.38.27 sklearn.utils.multiclass.type_of_target

sklearn.utils.multiclass.type_of_target(y)
Determine the type of data indicated by the target.
Note that this type is the most specific type that can be inferred. For example:

• binary is more specific but compatible with multiclass.
• multiclass of integers is more specific but compatible with continuous.
• multilabel-indicator is more specific but compatible with multiclass-multioutput.

Parameters
y [array-like]

Returns
target_type [str] One of:

• ‘continuous’: y is an array-like of floats that are not all integers, and is 1d or a column vector.
• ‘continuous-multioutput’: y is a 2d array of floats that are not all integers, and both dimensions are of size > 1.
• ‘binary’: y contains <= 2 discrete values and is 1d or a column vector.
• ‘multiclass’: y contains more than two discrete values, is not a sequence of sequences, and is 1d or a column vector.
• ‘multiclass-multioutput’: y is a 2d array that contains more than two discrete values, is not a sequence of sequences, and both dimensions are of size > 1.
• ‘multilabel-indicator’: y is a label indicator matrix, an array of two dimensions with at least two columns, and at most 2 unique values.
• ‘unknown’: y is array-like but none of the above, such as a 3d array, sequence of sequences, or an array of non-sequence objects.

Examples

>>> import numpy as np
>>> type_of_target([0.1, 0.6])
'continuous'
>>> type_of_target([1, -1, -1, 1])
'binary'
>>> type_of_target(['a', 'b', 'a'])
'binary'
>>> type_of_target([1.0, 2.0])
'binary'
>>> type_of_target([1, 0, 2])
'multiclass'
>>> type_of_target([1.0, 0.0, 3.0])
(continues on next page)
'multiclass'
>>> type_of_target(['a', 'b', 'c'])
'multiclass'
>>> type_of_target(np.array([[1, 2], [3, 1]]))
'multiclass-multioutput'
>>> type_of_target([[1, 2]])
'multilabel-indicator'
>>> type_of_target(np.array([[1.5, 2.0], [3.0, 1.6]]))
'continuous-multioutput'
>>> type_of_target(np.array([[0, 1], [1, 1]]))
'multilabel-indicator'

7.38.28 sklearn.utils.multiclass.is_multilabel

sklearn.utils.multiclass.is_multilabel(y)
Check if y is in a multilabel format.

Parameters
y [ndarray of shape (n_samples,)] Target values.

Returns
out [bool] Return True, if y is in a multilabel format, else `False.

Examples

>>> import numpy as np
>>> from sklearn.utils.multiclass import is_multilabel
>>> is_multilabel([0, 1, 0, 1])
False
>>> is_multilabel([[1], [0, 2], []])
False
>>> is_multilabel(np.array([[1, 0], [0, 0]]))
True
>>> is_multilabel(np.array([[1], [0], [0]]))
False
>>> is_multilabel(np.array([[1, 0, 0]]))
True

7.38.29 sklearn.utils.multiclass.unique_labels

sklearn.utils.multiclass.unique_labels(*ys)
Extract an ordered array of unique labels.

We don’t allow:

- mix of multilabel and multiclass (single label) targets
- mix of label indicator matrix and anything else, because there are no explicit labels
- mix of label indicator matrices of different sizes
- mix of string and integer labels

At the moment, we also don’t allow “multiclass-multioutput” input type.
Parameters

*ys [array-likes]

Returns

out [ndarray of shape (n_unique_labels,)] An ordered array of unique labels.

Examples

```python
>>> from sklearn.utils.multiclass import unique_labels
>>> unique_labels([3, 5, 5, 5, 7, 7])
array([3, 5, 7])
>>> unique_labels([1, 2, 3, 4], [2, 2, 3, 4])
array([1, 2, 3, 4])
>>> unique_labels([1, 2, 10], [5, 11])
array([ 1,  2,  5, 10, 11])
```

7.38.30 sklearn.utils.murmurhash3_32

sklearn.utils.murmurhash3_32()

Compute the 32bit murmurhash3 of key at seed.

The underlying implementation is MurmurHash3_x86_32 generating low latency 32bits hash suitable for implementing lookup tables, Bloom filters, count min sketch or feature hashing.

Parameters

key [np.int32, bytes, unicode or ndarray of dtype=np.int32] The physical object to hash.

seed [int, default=0] Integer seed for the hashing algorithm.

positive [bool, default=False]

   True: the results is casted to an unsigned int from 0 to 2 ** 32 - 1

   False: the results is casted to a signed int from -(2 ** 31) to 2 ** 31 - 1

7.38.31 sklearn.utils.resample

sklearn.utils.resample(*arrays, replace=True, n_samples=None, random_state=None, stratify=None)

Resample arrays or sparse matrices in a consistent way.

The default strategy implements one step of the bootstrapping procedure.

Parameters

*arrays [sequence of array-like of shape (n_samples,) or (n_samples, n_outputs)] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

replace [bool, default=True] Implements resampling with replacement. If False, this will implement (sliced) random permutations.

n_samples [int, default=None] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. If replace is False it should not be larger than the length of arrays.
**random_state** [int, RandomState instance or None, default=None] Determines random number generation for shuffling the data. Pass an int for reproducible results across multiple function calls. See Glossary.

**stratify** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] If not None, data is split in a stratified fashion, using this as the class labels.

**Returns**

resampled_arrays [sequence of array-like of shape (n_samples,) or (n_samples, n_outputs)]

Sequence of resampled copies of the collections. The original arrays are not impacted.

See also:

shuffle

**Examples**

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])
>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)
>>> from sklearn.utils import resample
>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)
>>> X
array([[1., 0.],
        [2., 1.],
        [1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
    with 4 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[1., 0.],
        [2., 1.],
        [1., 0.]])

>>> y
array([0, 1, 0])

>>> resample(y, n_samples=2, random_state=0)
array([0, 1])
```

Example using stratification:

```python
>>> y = [0, 0, 1, 1, 1, 1, 1, 1]
>>> resample(y, n_samples=5, replace=False, stratify=y,
        random_state=0)
[1, 1, 1, 0, 1]
```
7.38.32 sklearn.utils._safe_indexing

```
sklearn.utils._safe_indexing(X, indices, *, axis=0)
```

Return rows, items or columns of X using indices.

**Parameters**

- **X** [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series] Data from which to sample rows, items or columns. list are only supported when axis=0.
- **indices** [bool, int, str, slice, array-like]
  - If axis=0, boolean and integer array-like, integer slice, and scalar integer are supported.
  - If axis=1:
    - to select a single column, indices can be of int type for all X types and str only for dataframe. The selected subset will be 1D, unless X is a sparse matrix in which case it will be 2D.
    - to select multiples columns, indices can be one of the following: list, array, slice. The type used in these containers can be one of the following: int, ‘bool’ and str. However, str is only supported when X is a dataframe. The selected subset will be 2D.
- **axis** [int, default=0] The axis along which X will be subsampled. axis=0 will select rows while axis=1 will select columns.

**Returns**

- **subset** Subset of X on axis 0 or 1.

**Notes**

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.

7.38.33 sklearn.utils.safe_mask

```
sklearn.utils.safe_mask(X, mask)
```

Return a mask which is safe to use on X.

**Parameters**

- **X** [array-like, sparse matrix] Data on which to apply mask.
- **mask** [ndarray] Mask to be used on X.

**Returns**

- **mask**
7.38.34 sklearn.utils.safe_sqr

sklearn.utils.safe_sqr(X, *, copy=True)
Element wise squaring of array-likes and sparse matrices.

Parameters

X [{array-like, ndarray, sparse matrix}]
copy [bool, default=True] Whether to create a copy of X and operate on it or to perform inplace computation (default behaviour).

Returns

X ** 2 [element wise square]

7.38.35 sklearn.utils.shuffle

sklearn.utils.shuffle(*arrays, random_state=None, n_samples=None)
Shuffle arrays or sparse matrices in a consistent way.

This is a convenience alias to resample(*arrays, replace=False) to do random permutations of the collections.

Parameters

*arrays [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

random_state [int, RandomState instance or None, default=None] Determines random number generation for shuffling the data. Pass an int for reproducible results across multiple function calls. See Glossary.

n_samples [int, default=None] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. It should not be larger than the length of arrays.

Returns

shuffled_arrays [sequence of indexable data-structures] Sequence of shuffled copies of the collections. The original arrays are not impacted.

See also:

resample

Examples

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import shuffle

>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)
```
array([[0., 0.],
       [1., 0.]]))

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
   with 3 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[0., 0.],
       [2., 1.],
       [1., 0.]])

>>> y
array([2, 1, 0])

>>> shuffle(y, n_samples=2, random_state=0)
array([0, 1])

Examples using sklearn.utils.shuffle

• Approximate nearest neighbors in TSNE

7.38.36 sklearn.utils.sparsefuncs.incr_mean_variance_axis

sklearn.utils.sparsefuncs.incr_mean_variance_axis(X, axis, last_mean, last_var, last_n)

Compute incremental mean and variance along an axix on a CSR or CSC matrix.

last_mean, last_var are the statistics computed at the last step by this function. Both must be initialized to 0-arrays of the proper size, i.e. the number of features in X. last_n is the number of samples encountered until now.

Parameters

X [CSR or CSC sparse matrix, shape (n_samples, n_features)] Input data.
axis [int (either 0 or 1)] Axis along which the axis should be computed.
last_mean [float array with shape (n_features,)] Array of feature-wise means to update with the new data X.
last_var [float array with shape (n_features,)] Array of feature-wise var to update with the new data X.
last_n [int with shape (n_features,)] Number of samples seen so far, excluded X.

Returns

means [float array with shape (n_features,)] Updated feature-wise means.
variances [float array with shape (n_features,)] Updated feature-wise variances.
n [int with shape (n_features,)] Updated number of seen samples.
Notes

NaNs are ignored in the algorithm.

7.38.37 sklearn.utils.sparsefuncs.inplace_column_scale

sklearn.utils.sparsefuncs.inplace_column_scale(X, scale)

Inplace column scaling of a CSC/CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters

X [CSC or CSR matrix with shape (n_samples, n_features)] Matrix to normalize using the variance of the features.

scale [float array with shape (n_features,)] Array of precomputed feature-wise values to use for scaling.

7.38.38 sklearn.utils.sparsefuncs.inplace_row_scale

sklearn.utils.sparsefuncs.inplace_row_scale(X, scale)

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters

X [CSR or CSC sparse matrix, shape (n_samples, n_features)] Matrix to be scaled.

scale [float array with shape (n_features,)] Array of precomputed sample-wise values to use for scaling.

7.38.39 sklearn.utils.sparsefuncs.inplace_swap_row

sklearn.utils.sparsefuncs.inplace_swap_row(X, m, n)

Swaps two rows of a CSC/CSR matrix in-place.

Parameters

X [CSR or CSC sparse matrix, shape=(n_samples, n_features)] Matrix whose two rows are to be swapped.

m [int] Index of the row of X to be swapped.

n [int] Index of the row of X to be swapped.
7.38.40 sklearn.utils.sparsefuncs.inplace_swap_column

sklearn.utils.sparsefuncs.inplace_swap_column(X, m, n)
Swaps two columns of a CSC/CSR matrix in-place.

Parameters
- X [CSR or CSC sparse matrix, shape=(n_samples, n_features)] Matrix whose two columns are to be swapped.
- m [int] Index of the column of X to be swapped.
- n [int] Index of the column of X to be swapped.

7.38.41 sklearn.utils.sparsefuncs.mean_variance_axis

sklearn.utils.sparsefuncs.mean_variance_axis(X, axis)
Compute mean and variance along an axis on a CSR or CSC matrix

Parameters
- X [CSR or CSC sparse matrix, shape (n_samples, n_features)] Input data.
- axis [int (either 0 or 1)] Axis along which the axis should be computed.

Returns
- means [float array with shape (n_features,)] Feature-wise means
- variances [float array with shape (n_features,)] Feature-wise variances

7.38.42 sklearn.utils.sparsefuncs.inplace_csr_column_scale

sklearn.utils.sparsefuncs.inplace_csr_column_scale(X, scale)
Inplace column scaling of a CSR matrix.
Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters
- X [CSR matrix with shape (n_samples, n_features)] Matrix to normalize using the variance of the features.
- scale [float array with shape (n_features,)] Array of precomputed feature-wise values to use for scaling.

7.38.43 sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1

sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1()
Inplace row normalize using the l1 norm
7.38.44 sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2

```
sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2()
```

Inplace row normalize using the l2 norm

7.38.45 sklearn.utils.random.sample_without_replacement

```
sklearn.utils.random.sample_without_replacement()
```

Sample integers without replacement.

Select n_samples integers from the set [0, n_population) without replacement.

**Parameters**

- n_population [int] The size of the set to sample from.
- n_samples [int] The number of integer to sample.
- random_state [int, RandomState instance or None, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- method [{"auto", "tracking_selection", "reservoir_sampling", "pool"}, default='auto'] If method == "auto", the ratio of n_samples / n_population is used to determine which algorithm to use: If ratio is between 0 and 0.01, tracking selection is used. If ratio is between 0.01 and 0.99, numpy.random.permutation is used. If ratio is greater than 0.99, reservoir sampling is used. The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method == "tracking_selection", a set based implementation is used which is suitable for n_samples <<< n_population.

If method == "reservoir_sampling", a reservoir sampling algorithm is used which is suitable for high memory constraint or when O(n_samples) ~ O(n_population). The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method == "pool", a pool based algorithm is particularly fast, even faster than the tracking selection method. However, a vector containing the entire population has to be initialized. If n_samples ~ n_population, the reservoir sampling method is faster.

**Returns**

- out [ndarray of shape (n_samples,)] The sampled subsets of integer. The subset of selected integer might not be randomized, see the method argument.

7.38.46 sklearn.utils.validation.check_is_fitted

```
sklearn.utils.validation.check_is_fitted(estimator, attributes=None, *, msg=None, all_or_any=<built-in function all>,
```

Perform is_fitted validation for estimator.

Checks if the estimator is fitted by verifying the presence of fitted attributes (ending with a trailing underscore) and otherwise raises a NotFittedError with the given message.

This utility is meant to be used internally by estimators themselves, typically in their own predict / transform methods.
Parameters

**estimator** [estimator instance] estimator instance for which the check is performed.

**attributes** [str, list or tuple of str, default=None] Attribute name(s) given as string or a list/tuple of strings. Eg.: "coef_", "estimator_", ...", "coef_"

If None, estimator is considered fitted if there exist an attribute that ends with a underscore and does not start with double underscore.

**msg** [str, default=None] The default error message is, “This %(name)s instance is not fitted yet. Call 'fit' with appropriate arguments before using this estimator.”

For custom messages if “%(name)s” is present in the message string, it is substituted for the estimator name.

Eg.: “Estimator, %(name)s, must be fitted before sparsifying”.

**all_or_any** [callable, {all, any}, default=all] Specify whether all or any of the given attributes must exist.

Returns

None

Raises

NotFittedError If the attributes are not found.

### 7.38.47 sklearn.utils.validation.check_memory

**sklearn.utils.validation.check_memory** *(memory)*

Check that memory is joblib.Memory-like.

joblib.Memory-like means that memory can be converted into a joblib.Memory instance (typically a str denoting the location) or has the same interface (has a cache method).

Parameters

**memory** [None, str or object with the joblib.Memory interface]

Returns

memory [object with the joblib.Memory interface]

Raises

ValueError If memory is not joblib.Memory-like.

### 7.38.48 sklearn.utils.validation.check_symmetric

**sklearn.utils.validation.check_symmetric** *(array, *, tol=1e-10, raise_warning=True, raise_exception=False)*

Make sure that array is 2D, square and symmetric.

If the array is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

Parameters

**array** [[ndarray, sparse matrix]] Input object to check / convert. Must be two-dimensional and square, otherwise a ValueError will be raised.
raise_warning  [bool, default=True] If True then raise a warning if conversion is required.
raise_exception  [bool, default=False] If True then raise an exception if array is not symmetric.

Returns
array_sym  [[ndarray, sparse matrix]] Symmetrized version of the input array, i.e. the average of array and array.transpose(). If sparse, then duplicate entries are first summed and zeros are eliminated.

7.38.49 sklearn.utils.validation.column_or_1d

sklearn.utils.validation.column_or_1d(y, *, warn=False)
Ravel column or 1d numpy array, else raises an error.

Parameters
y  [array-like]
warn  [bool, default=False] To control display of warnings.

Returns
y  [ndarray]

7.38.50 sklearn.utils.validation.has_fit_parameter

sklearn.utils.validation.has_fit_parameter(estimator, parameter)
Checks whether the estimator’s fit method supports the given parameter.

Parameters
estimator  [object] An estimator to inspect.
parameter  [str] The searched parameter.

Returns
is_parameter: bool  Whether the parameter was found to be a named parameter of the estimator’s fit method.

Examples

```python
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```
7.38.51 sklearn.utils.all_estimators

sklearn.utils.all_estimators(type_filter=None)

Get a list of all estimators from sklearn.

This function crawls the module and gets all classes that inherit from BaseEstimator. Classes that are defined in test-modules are not included.

Parameters

- **type_filter** (["classifier", "regressor", "cluster", "transformer"] or list of such str, default=None) Which kind of estimators should be returned. If None, no filter is applied and all estimators are returned. Possible values are 'classifier', 'regressor', 'cluster' and 'transformer' to get estimators only of these specific types, or a list of these to get the estimators that fit at least one of the types.

Returns

- **estimators** [list of tuples] List of (name, class), where name is the class name as string and class is the actual type of the class.

Utilities from joblib:

- **utils.paralllel_backend(backend[, n_jobs, ...])** Change the default backend used by Parallel inside a with block.
- **utils.register_parallel_backend(name, factory)** Register a new Parallel backend factory.

7.38.52 sklearn.utils.parallel_backend

sklearn.utils.parallel_backend(backend, n_jobs=-1, inner_max_num_threads=None, **backend_params)

Change the default backend used by Parallel inside a with block.

If backend is a string it must match a previously registered implementation using the register_parallel_backend function.

By default the following backends are available:

- ‘loky’: single-host, process-based parallelism (used by default),
- ‘threading’: single-host, thread-based parallelism,
- ‘multiprocessing’: legacy single-host, process-based parallelism.

‘loky’ is recommended to run functions that manipulate Python objects. ‘threading’ is a low-overhead alternative that is most efficient for functions that release the Global Interpreter Lock: e.g. I/O-bound code or CPU-bound code in a few calls to native code that explicitly releases the GIL.

In addition, if the dask and distributed Python packages are installed, it is possible to use the ‘dask’ backend for better scheduling of nested parallel calls without over-subscription and potentially distribute parallel calls over a networked cluster of several hosts.

It is also possible to use the distributed ‘ray’ backend for distributing the workload to a cluster of nodes. To use the ‘ray’ joblib backend add the following lines:

```python
>> from ray.util.joblib import register_ray >> register_ray() >> with parallel_backend("ray"): ..
print(Parallel()(delayed(neg)(i + 1) for i in range(5))) [-1, -2, -3, -4, -5]
```

Alternatively the backend can be passed directly as an instance.
By default all available workers will be used (n_jobs=-1) unless the caller passes an explicit value for the n_jobs parameter.

This is an alternative to passing a backend='backend_name' argument to the Parallel class constructor. It is particularly useful when calling into library code that uses joblib internally but does not expose the backend argument in its own API.

```python
>>> from operator import neg
>>> with parallel_backend('threading'):
...     print(Parallel()(delayed(neg)(i + 1) for i in range(5)))
...  
[-1, -2, -3, -4, -5]
```

Warning: this function is experimental and subject to change in a future version of joblib.

Joblib also tries to limit the oversubscription by limiting the number of threads usable in some third-party library threadpools like OpenBLAS, MKL or OpenMP. The default limit in each worker is set to \( \max(\text{cpu_count}() \div \text{effective_n_jobs}, 1) \) but this limit can be overwritten with the inner_max_num_threads argument which will be used to set this limit in the child processes.

New in version 0.10.

### 7.38.53 sklearn.utils.register_parallel_backend

`sklearn.utils.register_parallel_backend(name, factory, make_default=False)`

Register a new Parallel backend factory.

The new backend can then be selected by passing its name as the backend argument to the Parallel class. Moreover, the default backend can be overwritten globally by setting make_default=True.

The factory can be any callable that takes no argument and return an instance of `ParallelBackendBase`.

Warning: this function is experimental and subject to change in a future version of joblib.

New in version 0.10.

#### 7.39.1 To be removed in 0.25
8.1 Contributing

This project is a community effort, and everyone is welcome to contribute.

The project is hosted on https://github.com/scikit-learn/scikit-learn

The decision making process and governance structure of scikit-learn is laid out in the governance document: Scikit-learn governance and decision-making.

Scikit-learn is somewhat selective when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See Issues for New Contributors to get started.

Our community, our values

We are a community based on openness and friendly, didactic, discussions.

We aspire to treat everybody equally, and value their contributions. We are particularly seeking people from under-represented backgrounds in Open Source Software and scikit-learn in particular to participate and contribute their expertise and experience.

Decisions are made based on technical merit and consensus.

Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.

We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: https://www.python.org/psf/codeofconduct/

In case you experience issues using this package, do not hesitate to submit a ticket to the GitHub issue tracker. You are also welcome to post feature requests or pull requests.
8.1.1 Ways to contribute

There are many ways to contribute to scikit-learn, with the most common ones being contribution of code or documentation to the project. Improving the documentation is no less important than improving the library itself. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request. Full documentation can be found under the doc/ directory.

But there are many other ways to help. In particular helping to improve, triage, and investigate issues and reviewing other developers’ pull requests are very valuable contributions that decrease the burden on the project maintainers.

Another way to contribute is to report issues you’re facing, and give a “thumbs up” on issues that others reported and that are relevant to you. It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply star to say “I use it”:

In case a contribution/issue involves changes to the API principles or changes to dependencies or supported versions, it must be backed by a Enhancement proposals (SLEPs), where a SLEP must be submitted as a pull-request to enhancement proposals using the SLEP template and follows the decision-making process outlined in Scikit-learn governance and decision-making.

Contributing to related projects

Scikit-learn thrives in an ecosystem of several related projects, which also may have relevant issues to work on, including smaller projects such as:

- scikit-learn-contrib
- joblib
- sphinx-gallery
- numpydoc
- liac-arff

and larger projects:

- numpy
- scipy
- matplotlib
- and so on.

Look for issues marked “help wanted” or similar. Helping these projects may help Scikit-learn too. See also Related Projects.

8.1.2 Submitting a bug report or a feature request

We use GitHub issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

In case you experience issues using this package, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other issues or pull requests.
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our new algorithm requirements.
If you are submitting a bug report, we strongly encourage you to follow the guidelines in *How to make a good bug report*.

### How to make a good bug report

When you submit an issue to Github, please do your best to follow these guidelines! This will make it a lot easier to provide you with good feedback:

- The ideal bug report contains a **short reproducible code snippet**, this way anyone can try to reproduce the bug easily (see this for more details). If your snippet is longer than around 50 lines, please link to a gist or a github repo.
- If not feasible to include a reproducible snippet, please be specific about what **estimators and/or functions are involved and the shape of the data**.
- If an exception is raised, please **provide the full traceback**.
- Please include your **operating system type and version number**, as well as your Python, scikit-learn, numpy, and scipy versions. This information can be found by running the following code snippet:

```python
>>> import sklearn
>>> sklearn.show_versions()
```

**Note:** This utility function is only available in scikit-learn v0.20+. For previous versions, one has to explicitly run:

```python
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

- Please ensure all **code snippets and error messages are formatted in appropriate code blocks**. See Creating and highlighting code blocks for more details.

If you want to help curate issues, read *the following*.

### 8.1.3 Contributing code

**Note:** To avoid duplicating work, it is highly advised that you search through the issue tracker and the PR list. If in doubt about duplicated work, or if you want to work on a non-trivial feature, it’s recommended to first open an issue in the issue tracker to get some feedbacks from core developers.

One easy way to find an issue to work on is by applying the “help wanted” label in your search. This lists all the issues that have been unclaimed so far. In order to claim an issue for yourself, please comment exactly **take on it** for the CI to automatically assign the issue to you.
Video resources

These videos are step-by-step introductions on how to contribute to scikit-learn, and are a great companion to the following text guidelines. Please make sure to still check our guidelines below, since they describe our latest up-to-date workflow.

- Crash Course in Contributing to Scikit-Learn & Open Source Projects: Video, Transcript
- Example of Submitting a Pull Request to scikit-learn: Video, Transcript

How to contribute

The preferred way to contribute to scikit-learn is to fork the main repository on GitHub, then submit a “pull request” (PR).

In the first few steps, we explain how to locally install scikit-learn, and how to set up your git repository:

1. Create an account on GitHub if you do not already have one.
2. Fork the project repository: click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub user account. For more details on how to fork a repository see this guide.
3. Clone your fork of the scikit-learn repo from your GitHub account to your local disk:

```bash
$ git clone git@github.com:YourLogin/scikit-learn.git
$ cd scikit-learn
```

4. Install the development dependencies:

```bash
$ pip install cython pytest pytest-cov flake8 mypy
```

5. Install scikit-learn in editable mode:

```bash
$ pip install --no-build-isolation --editable .
```

If you receive errors in building scikit-learn, see the Building from source section.

6. Add the upstream remote. This saves a reference to the main scikit-learn repository, which you can use to keep your repository synchronized with the latest changes:

```bash
$ git remote add upstream https://github.com/scikit-learn/scikit-learn.git
```

You should now have a working installation of scikit-learn, and your git repository properly configured. The next steps now describe the process of modifying code and submitting a PR:

7. Synchronize your master branch with the upstream master branch:

```bash
$ git checkout master
$ git pull upstream master
```

8. Create a feature branch to hold your development changes:

```bash
$ git checkout -b my_feature
```

and start making changes. Always use a feature branch. It’s good practice to never work on the master branch!

9. (Optional) Install pre-commit to run code style checks before each commit:
$ pip install pre-commit
$ pre-commit install

pre-commit checks can be disabled for a particular commit with `git commit -n`.

10. Develop the feature on your feature branch on your computer, using Git to do the version control. When you’re done editing, add changed files using `git add` and then `git commit`:

   $ git add modified_files
   $ git commit

to record your changes in Git, then push the changes to your GitHub account with:

   $ git push -u origin my_feature

11. Follow these instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

   **Note:** If you are modifying a Cython module, you have to re-compile after modifications and before testing them:

   ```
   pip install --no-build-isolation -e .
   ```

   Use the `--no-build-isolation` flag to avoid compiling the whole project each time, only the files you have modified.

   It is often helpful to keep your local feature branch synchronized with the latest changes of the main scikit-learn repository:

   ```
   $ git fetch upstream
   $ git merge upstream/master
   ```

   Subsequently, you might need to solve the conflicts. You can refer to the Git documentation related to resolving merge conflict using the command line.

   **Learning git:**

   The [Git documentation](https://git-scm.com/docs) and [http://try.github.io](http://try.github.io) are excellent resources to get started with git, and understanding all of the commands shown here.

**Pull request checklist**

Before a PR can be merged, it needs to be approved by two core developers. Please prefix the title of your pull request with `[MRG]` if the contribution is complete and should be subjected to a detailed review. An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed `[WIP]` (to indicate a work in progress) and changed to `[MRG]` when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a task list in the PR description.

In order to ease the reviewing process, we recommend that your contribution complies with the following rules before marking a PR as `[MRG]`. The **bolded** ones are especially important:

1. **Give your pull request a helpful title** that summarises what your contribution does. This title will often become the commit message once merged so it should summarise your contribution for posterity. In some cases “Fix `<ISSUE TITLE>`” is enough. “Fix `#<ISSUE NUMBER>`” is never a good title.
2. **Make sure your code passes the tests.** The whole test suite can be run with `pytest`, but it is usually not recommended since it takes a long time. It is often enough to only run the test related to your changes: for example, if you changed something in `sklearn/linear_model/logistic.py`, running the following commands will usually be enough:

- `pytest sklearn/linear_model/logistic.py` to make sure the doctest examples are correct
- `pytest sklearn/linear_model/tests/test_logistic.py` to run the tests specific to the file
- `pytest sklearn/linear_model` to test the whole `linear_model` module
- `pytest doc/modules/linear_model.rst` to make sure the user guide examples are correct.
- `pytest sklearn/tests/test_common.py -k LogisticRegression` to run all our estimator checks (specifically for LogisticRegression, if that’s the estimator you changed).

There may be other failing tests, but they will be caught by the CI so you don’t need to run the whole test suite locally. For guidelines on how to use `pytest` efficiently, see the `Useful pytest aliases and flags`.

3. **Make sure your code is properly commented and documented,** and make sure the documentation renders properly. To build the documentation, please refer to our `Documentation` guidelines. The CI will also build the docs: please refer to `Generated documentation on CircleCI`.

4. **Tests are necessary for enhancements to be accepted.** Bug-fixes or new features should be provided with non-regression tests. These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. In the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.

5. **Make sure that your PR does not add PEP8 violations.** To check the code that you changed, you can run the following command (see `above` to set up the upstream remote):

   ```bash
   git diff upstream/master -u -- "*.py" | flake8 --diff
   ```
   
or make `flake8-diff` which should work on unix-like system.

6. Follow the `Coding guidelines`.

7. When applicable, use the validation tools and scripts in the `sklearn.utils` submodule. A list of utility routines available for developers can be found in the `Utilities for Developers` page.

8. Often pull requests resolve one or more other issues (or pull requests). If merging your pull request means that some other issues/PRs should be closed, you should use keywords to create link to them (e.g., `Fixes #1234`; multiple issues/PRs are allowed as long as each one is preceded by a keyword). Upon merging, those issues/PRs will automatically be closed by GitHub. If your pull request is simply related to some other issues/PRs, create a link to them without using the keywords (e.g., `See also #1234`).

9. PRs should often substantiate the change, through benchmarks of performance and efficiency (see `Monitoring performance`) or through examples of usage. Examples also illustrate the features and intricacies of the library to users. Have a look at other examples in the `examples/` directory for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.

10. New features often need to be illustrated with narrative documentation in the user guide, with small code snippets. If relevant, please also add references in the literature, with PDF links when possible.

11. The user guide should also include expected time and space complexity of the algorithm and scalability, e.g., “this algorithm can scale to a large number of samples > 100000, but does not scale in dimensionality: n_features is expected to be lower than 100”.

You can also check our Code Review Guidelines to get an idea of what reviewers will expect.

You can check for common programming errors with the following tools:

• Code with a good unittest coverage (at least 80%, better 100%), check with:

```
$ pip install pytest pytest-cov
$ pytest --cov sklearn path/to/tests_for_package
```

see also Testing and improving test coverage

• A moderate use of type annotations is encouraged but is not mandatory. See mypy quickstart for an introduction, as well as pandas contributing documentation for style guidelines. Whether you add type annotation or not:

```python
mypy sklearn
```

must not produce new errors in your pull request. Using `# type: ignore` annotation can be a workaround for a few cases that are not supported by mypy, in particular,

– when importing C or Cython modules
– on properties with decorators

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (see Monitoring performance).

Also check out the How to optimize for speed guide for more details on profiling and Cython optimizations.

**Note:** The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

**Note:** For two very well documented and more detailed guides on development workflow, please pay a visit to the Scipy Development Workflow - and the Astropy Workflow for Developers sections.

**Continuous Integration (CI)**

• Azure pipelines are used for testing scikit-learn on Linux, Mac and Windows, with different dependencies and settings.

• CircleCI is used to build the docs for viewing, for linting with flake8, and for testing with PyPy on Linux

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

<table>
<thead>
<tr>
<th>Commit Marker</th>
<th>Message</th>
<th>Action Taken by CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ci skip]</td>
<td>CI is skipped completely</td>
<td></td>

</table>
Stalled pull requests

As contributing a feature can be a lengthy process, some pull requests appear inactive but unfinished. In such a case, taking them over is a great service for the project.

A good etiquette to take over is:

• **Determine if a PR is stalled**

  – A pull request may have the label “stalled” or “help wanted” if we have already identified it as a candidate for other contributors.

  – To decide whether an inactive PR is stalled, ask the contributor if she/he plans to continue working on the PR in the near future. Failure to respond within 2 weeks with an activity that moves the PR forward suggests that the PR is stalled and will result in tagging that PR with “help wanted”.

    Note that if a PR has received earlier comments on the contribution that have had no reply in a month, it is safe to assume that the PR is stalled and to shorten the wait time to one day.

  After a sprint, follow-up for un-merged PRs opened during sprint will be communicated to participants at the sprint, and those PRs will be tagged “sprint”. PRs tagged with “sprint” can be reassigned or declared stalled by sprint leaders.

• **Taking over a stalled PR**: To take over a PR, it is important to comment on the stalled PR that you are taking over and to link from the new PR to the old one. The new PR should be created by pulling from the old one.

Stalled and Unclaimed Issues

Generally speaking, issues which are up for grabs will have a “help wanted” tag. However, not all issues which need contributors will have this tag, as the “help wanted” tag is not always up-to-date with the state of the issue. Contributors can find issues which are still up for grabs using the following guidelines:

• First, to **determine if an issue is claimed**:

  – Check for linked pull requests

  – Check the conversation to see if anyone has said that they’re working on creating a pull request

• If a contributor comments on an issue to say they are working on it, a pull request is expected within 2 weeks (new contributor) or 4 weeks (contributor or core dev), unless an larger time frame is explicitly given. Beyond that time, another contributor can take the issue and make a pull request for it. We encourage contributors to comment directly on the stalled or unclaimed issue to let community members know that they will be working on it.

• If the issue is linked to a stalled pull request, we recommend that contributors follow the procedure described in the *Stalled pull requests* section rather than working directly on the issue.

Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle “easy” issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!
good first issue tag

A great way to start contributing to scikit-learn is to pick an item from the list of good first issues in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. If you have already contributed to scikit-learn, you should look at Easy issues instead.

Easy tag

If you have already contributed to scikit-learn, another great way to contribute to scikit-learn is to pick an item from the list of Easy issues in the issue tracker. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

help wanted tag

We often use the help wanted tag to mark issues regardless of difficulty. Additionally, we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the help wanted tag can be found here.

Note that not all issues which need contributors will have this tag.

8.1.4 Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one), tutorials, etc. reStructuredText documents live in the source code repository under the doc/ directory.

You can edit the documentation using any text editor, and then generate the HTML output by typing make from the doc/ directory. Alternatively, make html may be used to generate the documentation with the example gallery (which takes quite some time). The resulting HTML files will be placed in _build/html/stable and are viewable in a web browser.

Building the documentation

First, make sure you have properly installed the development version.

Building the documentation requires installing some additional packages:

```bash
pip install sphinx sphinx-gallery numpydoc matplotlib Pillow pandas
scikit-image packaging seaborn
```

To build the documentation, you need to be in the doc folder:

```bash
cd doc
```

In the vast majority of cases, you only need to generate the full web site, without the example gallery:

```bash
make
```

The documentation will be generated in the _build/html/stable directory. To also generate the example gallery you can use:
This will run all the examples, which takes a while. If you only want to generate a few examples, you can use:

```
EXAMPLES_PATTERN=your_regex_goes_here make html
```

This is particularly useful if you are modifying a few examples.

Set the environment variable `NO_MATHJAX=1` if you intend to view the documentation in an offline setting.

To build the PDF manual, run:

```
make latexpdf
```

---

Warning: Sphinx version

While we do our best to have the documentation build under as many versions of Sphinx as possible, the different versions tend to behave slightly differently. To get the best results, you should use the same version as the one we used on CircleCI. Look at this [github search](https://github.com) to know the exact version.

---

Guidelines for writing documentation

It is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the reader on what the algorithm does.

Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including “big O” ($O(g(n))$) complexities of the algorithm, as opposed to just rules of thumb, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works “under the hood”.

Finally, follow the formatting rules below to make it consistently good:

- Add “See Also” in docstrings for related classes/functions.
- “See Also” in docstrings should be one line per reference, with a colon and an explanation, for example:

  ```
  See Also
  --------
  SelectKBest : Select features based on the k highest scores.
  SelectFpr : Select features based on a false positive rate test.
  ```

- When documenting the parameters and attributes, here is a list of some well-formatted examples:

  ```
  n_clusters : int, default=3
  The number of clusters detected by the algorithm.
  some_param : {'hello', 'goodbye'}, bool or int, default=True
  ```
The parameter description goes here, which can be either a string literal (either 'hello' or 'goodbye'), a bool, or an int. The default value is True.

array_parameter : {array-like, sparse matrix} of shape (n_samples, n_features) or
→(n_samples,)
This parameter accepts data in either of the mentioned forms, with one of the mentioned shapes. The default value is 'np.ones(shape=(n_samples,))'.

list_param : list of int

typed_ndarray : ndarray of shape (n_samples,), dtype=np.int32

sample_weight : array-like of shape (n_samples,), default=None

In general have the following in mind:

1. Use Python basic types. (bool instead of boolean)

2. Use parenthesis for defining shapes: array-like of shape (n_samples,) or array-like of shape (n_samples, n_features)

3. For strings with multiple options, use brackets: input: {'log', 'squared', 'multinomial'}

4. 1D or 2D data can be a subset of {array-like, ndarray, sparse matrix, dataframe}. Note that array-like can also be a list, while ndarray is explicitly only a numpy.ndarray.

5. Specify dataframe when “frame-like” features are being used, such as the column names.

6. When specifying the data type of a list, use of as a delimiter: list of int.

7. When specifying the dtype of an ndarray, use e.g. dtype=np.int32 after defining the shape: ndarray of shape (n_samples,), dtype=np.int32.

8. When the default is None, None only needs to be specified at the end with default=None. Be sure to include in the docstring, what it means for the parameter or attribute to be None.

- For unwritten formatting rules, try to follow existing good works:
  - For “References” in docstrings, see the Silhouette Coefficient (sklearn.metrics.silhouette_score).

- When editing reStructuredText (.rst) files, try to keep line length under 80 characters when possible (exceptions include links and tables).

- Do not modify sphinx labels as this would break existing cross references and external links pointing to specific sections in the scikit-learn documentation.

- Before submitting your pull request check if your modifications have introduced new sphinx warnings and try to fix them.
Generated documentation on CircleCI

When you change the documentation in a pull request, CircleCI automatically builds it. To view the documentation generated by CircleCI, simply go at the bottom of your PR page and look for the “ci/circleci: doc artifact” link.

8.1.5 Testing and improving test coverage

High-quality unit testing is a corner-stone of the scikit-learn development process. For this purpose, we use the pytest package. The tests are functions appropriately named, located in tests subdirectories, that check the validity of the algorithms and the different options of the code.

Running pytest in a folder will run all the tests of the corresponding subpackages. For a more detailed pytest workflow, please refer to the Pull request checklist.

We expect code coverage of new features to be at least around 90%.

Writing matplotlib related tests

Test fixtures ensure that a set of tests will be executing with the appropriate initialization and cleanup. The scikit-learn test suite implements a fixture which can be used with matplotlib.

pyplot The pyplot fixture should be used when a test function is dealing with matplotlib. matplotlib is a soft dependency and is not required. This fixture is in charge of skipping the tests if matplotlib is not installed. In addition, figures created during the tests will be automatically closed once the test function has been executed.

To use this fixture in a test function, one needs to pass it as an argument:

```python
def test_requiring_mpl_fixture(pyplot):
    # you can now safely use matplotlib
```

Workflow to improve test coverage

To test code coverage, you need to install the coverage package in addition to pytest.

1. Run ‘make test-coverage’. The output lists for each file the line numbers that are not tested.
2. Find a low hanging fruit, looking at which lines are not tested, write or adapt a test specifically for these lines.
3. Loop.

8.1.6 Monitoring performance

This section is heavily inspired from the pandas documentation.

When proposing changes to the existing code base, it’s important to make sure that they don’t introduce performance regressions. Scikit-learn uses asv benchmarks to monitor the performance of a selection of common estimators and functions. The benchmark suite can be found in the scikit-learn/asv_benchmarks directory.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

First of all you need to install the development version of asv:
pip install git+https://github.com/airspeed-velocity/asv

and change your directory to `asv_benchmarks/`:

cd asv_benchmarks/

The benchmark suite is configured to run against your local clone of scikit-learn. Make sure it is up to date:

git fetch upstream

In the benchmark suite, the benchmarks are organized following the same structure as scikit-learn. For example, you can compare the performance of a specific estimator between upstream/master and the branch you are working on:

`asv continuous -b LogisticRegression upstream/master HEAD`

The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, use the `-E` flag:

`asv continuous -E virtualenv -b LogisticRegression upstream/master HEAD`

You can also specify a whole module to benchmark:

`asv continuous -b linear_model upstream/master HEAD`

You can replace `HEAD` by any local branch. By default it will only report the benchmarks that have change by at least 10%. You can control this ratio with the `-f` flag.

To run the full benchmark suite, simply remove the `-b` flag

`asv continuous upstream/master HEAD`

However this can take up to two hours. The `-b` flag also accepts a regular expression for a more complex subset of benchmarks to run.

To run the benchmarks without comparing to another branch, use the `run` command:

`asv run -b linear_model HEAD^!`

You can also run the benchmark suite using the version of scikit-learn already installed in your current Python environment:

`asv run --python=same`

It’s particularly useful when you installed scikit-learn in editable mode to avoid creating a new environment each time you run the benchmarks. By default the results are not saved when using an existing installation. To save the results you must specify a commit hash:

`asv run --python=same --set-commit-hash=<commit hash>`

Benchmarks are saved and organized by machine, environment and commit. To see the list of all saved benchmarks:

`asv show`

and to see the report of a specific run:

`asv show <commit hash>`
When running benchmarks for a pull request you’re working on please report the results on github.

The benchmark suite supports additional configurable options which can be set in the `benchmarks/config.json` configuration file. For example, the benchmarks can run for a provided list of values for the `n_jobs` parameter.

More information on how to write a benchmark and how to use asv can be found in the asv documentation.

### 8.1.7 Issue Tracker Tags

All issues and pull requests on the GitHub issue tracker should have (at least) one of the following tags:

- **Bug / Crash**: Something is happening that clearly shouldn’t happen. Wrong results as well as unexpected errors from estimators go here.
- **Cleanup / Enhancement**: Improving performance, usability, consistency.
- **Documentation**: Missing, incorrect or sub-standard documentations and examples.
- **New Feature**: Feature requests and pull requests implementing a new feature.

There are four other tags to help new contributors:

- **good first issue**: This issue is ideal for a first contribution to scikit-learn. Ask for help if the formulation is unclear. If you have already contributed to scikit-learn, look at Easy issues instead.
- **Easy**: This issue can be tackled without much prior experience.
- **Moderate**: Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.
- **help wanted**: This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

### 8.1.8 Maintaining backwards compatibility

**Deprecation**

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function `zero_one` is renamed to `zero_one_loss`, we add the decorator `deprecated` (from `sklearn.utils`) to `zero_one` and call `zero_one_loss` from that function:

```python
from ..utils import deprecated

def zero_one_loss(y_true, y_pred, normalize=True):
    # actual implementation
    pass

@deprecated("Function 'zero_one' was renamed to 'zero_one_loss' in version 0.13 and will be removed in release 0.15. "
            "Default behavior is changed from 'normalize=False' to "
            "'normalize=True'")
def zero_one(y_true, y_pred, normalize=False):
    return zero_one_loss(y_true, y_pred, normalize)
```

If an attribute is to be deprecated, use the decorator `deprecated` on a property. Please note that the property decorator should be placed before the `deprecated` decorator for the docstrings to be rendered properly. E.g., renaming an attribute `labels_` to `classes_` can be done as:
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
"will be removed in 0.15. Use 'classes_' instead")
@property
def labels_(self):
    return self.classes_

If a parameter has to be deprecated, a `FutureWarning` warning must be raised too. In the following example, k is deprecated and renamed to n_clusters:

```python
import warnings
def example_function(n_clusters=8, k='deprecated '):
    if k != 'deprecated ':
        warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
        "will be removed in 0.15. ",
        FutureWarning)
    n_clusters = k
```

When the change is in a class, we validate and raise warning in `fit`:

```python
import warnings
class ExampleEstimator(BaseEstimator):
    def __init__(self, n_clusters=8, k='deprecated '):
        self.n_clusters = n_clusters
        self.k = k

    def fit(self, X, y):
        if self.k != 'deprecated ':
            warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
            "will be removed in 0.15. ",
            FutureWarning)
            self._n_clusters = self.k
        else:
            self._n_clusters = self.n_clusters
```

As in these examples, the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed. If the deprecation happened in version 0.x-dev, the message should say deprecation occurred in version 0.x and the removal will be in 0.(x+2), so that users will have enough time to adapt their code to the new behaviour. For example, if the deprecation happened in version 0.18-dev, the message should say it happened in version 0.18 and the old behavior will be removed in version 0.20.

In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation warning as explained above. Use the `.. deprecated::` directive:

```rst
.. deprecated:: 0.13
    'k' was renamed to 'n_clusters' in version 0.13 and will be removed
    in 0.15.
```

What’s more, a deprecation requires a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.
Change the default value of a parameter

If the default value of a parameter needs to be changed, please replace the default value with a specific value (e.g., warn) and raise FutureWarning when users are using the default value. In the following example, we change the default value of n_clusters from 5 to 10 (current version is 0.20):

```python
import warnings

def example_function(n_clusters='warn'):
    if n_clusters == 'warn':
        warnings.warn("The default value of n_clusters will change from "
                     "5 to 10 in 0.22.", FutureWarning)
    n_clusters = 5
```

When the change is in a class, we validate and raise warning in fit:

```python
import warnings

class ExampleEstimator:
    def __init__(self, n_clusters='warn'):
        self.n_clusters = n_clusters

    def fit(self, X, y):
        if self.n_clusters == 'warn':
            warnings.warn("The default value of n_clusters will change from "
                           "5 to 10 in 0.22.", FutureWarning)
        self._n_clusters = 5
```

Similar to deprecations, the warning message should always give both the version in which the change happened and the version in which the old behavior will be removed. The docstring needs to be updated accordingly. We need a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

8.1.9 Code Review Guidelines

Reviewing code contributed to the project as PRs is a crucial component of scikit-learn development. We encourage anyone to start reviewing code of other developers. The code review process is often highly educational for everybody involved. This is particularly appropriate if it is a feature you would like to use, and so can respond critically about whether the PR meets your needs. While each pull request needs to be signed off by two core developers, you can speed up this process by providing your feedback.

Here are a few important aspects that need to be covered in any code review, from high-level questions to a more detailed check-list.

- Do we want this in the library? Is it likely to be used? Do you, as a scikit-learn user, like the change and intend to use it? Is it in the scope of scikit-learn? Will the cost of maintaining a new feature be worth its benefits?
- Is the code consistent with the API of scikit-learn? Are public functions/classes/parameters well named and intuitively designed?
- Are all public functions/classes and their parameters, return types, and stored attributes named according to scikit-learn conventions and documented clearly?
- Is any new functionality described in the user-guide and illustrated with examples?
- Is every public function/class tested? Are a reasonable set of parameters, their values, value types, and combinations tested? Do the tests validate that the code is correct, i.e. doing what the documentation says it does? If the change is a bug-fix, is a non-regression test included? Look at this to get started with testing in Python.
• Do the tests pass in the continuous integration build? If appropriate, help the contributor understand why tests failed.

• Do the tests cover every line of code (see the coverage report in the build log)? If not, are the lines missing coverage good exceptions?

• Is the code easy to read and low on redundancy? Should variable names be improved for clarity or consistency? Should comments be added? Should comments be removed as unhelpful or extraneous?

• Could the code easily be rewritten to run much more efficiently for relevant settings?

• Is the code backwards compatible with previous versions? (or is a deprecation cycle necessary?)

• Will the new code add any dependencies on other libraries? (this is unlikely to be accepted)

• Does the documentation render properly (see the Documentation section for more details), and are the plots instructive?

Standard replies for reviewing includes some frequent comments that reviewers may make.

8.1.10 Reading the existing code base

Reading and digesting an existing code base is always a difficult exercise that takes time and experience to master. Even though we try to write simple code in general, understanding the code can seem overwhelming at first, given the sheer size of the project. Here is a list of tips that may help make this task easier and faster (in no particular order).

• Get acquainted with the APIs of scikit-learn objects: understand what fit, predict, transform, etc. are used for.

• Before diving into reading the code of a function / class, go through the docstrings first and try to get an idea of what each parameter / attribute is doing. It may also help to stop a minute and think how would I do this myself if I had to?

• The trickiest thing is often to identify which portions of the code are relevant, and which are not. In scikit-learn a lot of input checking is performed, especially at the beginning of the fit methods. Sometimes, only a very small portion of the code is doing the actual job. For example looking at the fit() method of LinearRegression, what you’re looking for might just be the call the scipy.linalg.lstsq, but it is buried into multiple lines of input checking and the handling of different kinds of parameters.

• Due to the use of Inheritance, some methods may be implemented in parent classes. All estimators inherit at least from BaseEstimator, and from a Mixin class (e.g. ClassifierMixin) that enables default behaviour depending on the nature of the estimator (classifier, regressor, transformer, etc.).

• Sometimes, reading the tests for a given function will give you an idea of what its intended purpose is. You can use git grep (see below) to find all the tests written for a function. Most tests for a specific function/class are placed under the tests/ folder of the module

• You’ll often see code looking like this: out = Parallel(...) (delayed(some_function)(param) for param in some_iterable). This runs some_function in parallel using Joblib. out is then an iterable containing the values returned by some_function for each call.

• We use Cython to write fast code. Cython code is located in .pyx and .pxd files. Cython code has a more C-like flavor: we use pointers, perform manual memory allocation, etc. Having some minimal experience in C / C++ is pretty much mandatory here.

• Master your tools.

  – With such a big project, being efficient with your favorite editor or IDE goes a long way towards digesting the code base. Being able to quickly jump (or peek) to a function/class/attribute definition helps a lot. So does being able to quickly see where a given name is used in a file.
– *git* also has some built-in killer features. It is often useful to understand how a file changed over time, using e.g. *git blame* (manual). This can also be done directly on GitHub. *git grep* (examples) is also extremely useful to see every occurrence of a pattern (e.g. a function call or a variable) in the code base.

# 8.2 Developing scikit-learn estimators

Whether you are proposing an estimator for inclusion in scikit-learn, developing a separate package compatible with scikit-learn, or implementing custom components for your own projects, this chapter details how to develop objects that safely interact with scikit-learn Pipelines and model selection tools.

## 8.2.1 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.

Elements of the scikit-learn API are described more definitively in the *Glossary of Common Terms and API Elements*.

### Different objects

The main objects in scikit-learn are (one class can implement multiple interfaces):

**Estimator** The base object, implements a *fit* method to learn from data, either:

```python
estimator = estimator.fit(data, targets)
```

or:

```python
estimator = estimator.fit(data)
```

**Predictor** For supervised learning, or some unsupervised problems, implements:

```python
prediction = predictor.predict(data)
```

Classification algorithms usually also offer a way to quantify certainty of a prediction, either using `decision_function` or `predict_proba`:

```python
probability = predictor.predict_proba(data)
```

**Transformer** For filtering or modifying the data, in a supervised or unsupervised way, implements:

```python
new_data = transformer.transform(data)
```

When fitting and transforming can be performed much more efficiently together than separately, implements:

```python
new_data = transformer.fit_transform(data)
```

**Model** A model that can give a goodness of fit measure or a likelihood of unseen data, implements (higher is better):

```python
```
Estimators

The API has one predominant object: the estimator. An estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the fit method:

```python
estimator.fit(X, y)
```

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`.

Instantiation

This concerns the creation of an object. The object’s `__init__` method might accept constants as arguments that determine the estimator’s behavior (like the C constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:

```python
clf2 = SVC(C=2.3)
clf3 = SVC([[1, 2], [2, 3]], [-1, 1]) # WRONG!
```

The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the “Attributes” section, but rather under the “Parameters” section for that estimator.

In addition, every keyword argument accepted by `__init__` should correspond to an attribute on the instance. Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```python
def __init__(self, param1=1, param2=2):
    self.param1 = param1
    self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:

```python
def __init__(self, param1=1, param2=2, param3=3):
    # WRONG: parameters should not be modified
    if param1 > 1:
        param2 += 1
    self.param1 = param1
    # WRONG: the object's attributes should have exactly the name of
    # the argument in the constructor
    self.param3 = param2
```

The reason for postponing the validation is that the same validation would have to be performed in `set_params`, which is used in algorithms like `GridSearchCV`. 

8.2. Developing scikit-learn estimators 2807
Fitting

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the `fit()` method.

The `fit()` method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using $X$ and $y$, but the object holds no reference to $X$ and $y$. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the predict method.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$X$</td>
<td>array-like of shape (n_samples, n_features)</td>
</tr>
<tr>
<td>$y$</td>
<td>array-like of shape (n_samples,)</td>
</tr>
<tr>
<td>kwargs</td>
<td>optional data-dependent parameters</td>
</tr>
</tbody>
</table>

$X$.shape[0] should be the same as $y$.shape[0]. If this requisite is not met, an exception of type `ValueError` should be raised.

$y$ might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a `y=None` keyword argument in the second position that is just ignored by the estimator. For the same reason, `fit_predict`, `fit_transform`, `score` and `partial_fit` methods need to accept a `y` argument in the second place if they are implemented.

The method should return the object (self). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, `fit` can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an `__init__` keyword argument. **Fit parameters should be restricted to directly data dependent variables.** For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix $X$ are data dependent. A tolerance stopping criterion `tol` is not directly data dependent (although the optimal value according to some scoring function probably is).

When `fit` is called, any previous call to `fit` should be ignored. In general, calling `estimator.fit(X1)` and then `estimator.fit(X2)` should be the same as only calling `estimator.fit(X2)`. However, this may not be true in practice when `fit` depends on some random process, see `random_state`. Another exception to this rule is when the hyper-parameter `warm_start` is set to `True` for estimators that support it. `warm_start=True` means that the previous state of the trainable parameters of the estimator are reused instead of using the default initialization strategy.

**Estimated Attributes**

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a `coef_` attribute after `fit` has been called. The estimated attributes are expected to be overridden when you call `fit` a second time.
Optional Arguments

In iterative algorithms, the number of iterations should be specified by an integer called `n_iter`.

Pairwise Attributes

An estimator that accepts \(X\) of shape \((n_{\text{samples}}, n_{\text{samples}})\) and defines a `pairwise` property equal to `True` allows for cross-validation of the dataset, e.g. when \(X\) is a precomputed kernel matrix. Specifically, the `pairwise` property is used by `utils.metaestimators._safe_split` to slice rows and columns.

Deprecation: Since version 0.24: The `pairwise` attribute is deprecated in 0.24. From 0.26 onward, the `pairwise` estimator tag should be used instead.

Universal attributes

Estimators that expect tabular input should set a `n_features_in_` attribute at `fit` time to indicate the number of features that the estimator expects for subsequent calls to `predict` or `transform`. See SLEP010 for details.

8.2.2 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running `check_estimator` on an instance. The `parametrize_with_checks` pytest decorator can also be used (see its docstring for details and possible interactions with pytest):

```python
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC
>>> check_estimator(LinearSVC())  # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as `model_selection.GridSearchCV` and `pipeline.Pipeline`.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.

**Project template:**

We provide a [project template](#) which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of `check_estimator`
- directory structures and scripts to compile documentation and example galleries
- scripts to manage continuous integration (testing on Linux and Windows)
- instructions from getting started to publishing on [PyPi](#)
**BaseEstimator and mixins:**

We tend to use "duck typing", so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from `BaseEstimator` and optionally the mixin classes in `sklearn.base`. For example, below is a custom classifier, with more examples included in the scikit-learn-contrib project template.

```python
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances

>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...     def __init__(self, demo_param='demo'):
...         self.demo_param = demo_param
...     def fit(self, X, y):
...         # Check that X and y have correct shape
...         X, y = check_X_y(X, y)
...         # Store the classes seen during fit
...         self.classes_ = unique_labels(y)
...         self.X_ = X
...         self.y_ = y
...         return self
...     def predict(self, X):
...         # Check is fit had been called
...         check_is_fitted(self)
...         # Input validation
...         X = check_array(X)
...         closest = np.argmin(euclidean_distances(X, self.X_), axis=1)
...         return self.y_[closest]
```

**get_params and set_params**

All scikit-learn estimators have `get_params` and `set_params` functions. The `get_params` function takes no arguments and returns a dict of the `__init__` parameters of the estimator, together with their values.

It must take one keyword argument, `deep`, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for `deep` should be `True`. For instance considering the following estimator:

```python
>>> from sklearn.base import BaseEstimator
>>> from sklearn.linear_model import LogisticRegression
>>> class MyEstimator(BaseEstimator):
...     def __init__(self, subestimator=None, my_extra_param="random"):
... (continues on next page)
```
The parameter deep will control whether or not the parameters of the subestimator should be reported. Thus when deep=True, the output will be:

```python
>>> my_estimator = MyEstimator(subestimator=LogisticRegression())
>>> for param, value in my_estimator.get_params(deep=True).items():
...    print(f'{param} -> {value}"
my_extra_param -> random
subestimator__C -> 1.0
subestimator__class_weight -> None
subestimator__dual -> False
subestimator__fit_intercept -> True
subestimator__intercept_scaling -> 1
subestimator__l1_ratio -> None
subestimator__max_iter -> 100
subestimator__multi_class -> auto
subestimator__n_jobs -> None
subestimator__penalty -> l2
subestimator__random_state -> None
subestimator__solver -> lbfgs
subestimator__tol -> 0.0001
subestimator__verbose -> 0
subestimator__warm_start -> False
subestimator -> LogisticRegression()
```

Often, the subestimator has a name (as e.g. named steps in a Pipeline object), in which case the key should become <name>__C, <name>__class_weight, etc.

While when deep=False, the output will be:

```python
>>> for param, value in my_estimator.get_params(deep=False).items():
...    print(f'{param} -> {value}"
my_extra_param -> random
subestimator -> LogisticRegression()
```

The set_params on the other hand takes as input a dict of the form 'parameter': value and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the get_params mechanism is not essential (see Cloning below), the set_params function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible __repr__ method, is to inherit from sklearn.base.BaseEstimator. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```python
def get_params(self, deep=True):
    # suppose this estimator has parameters "alpha" and "recursive"
    return {"alpha": self.alpha, "recursive": self.recursive}

def set_params(self, **parameters):
    for parameter, value in parameters.items():
        setattr(self, parameter, value)
    return self
```

8.2. Developing scikit-learn estimators
Parameters and init

As `model_selection.GridSearchCV` uses `set_params` to apply parameter setting to estimators, it is essential that calling `set_params` has the same effect as setting parameters using the `__init__` method. The easiest and recommended way to accomplish this is to **not do any parameter validation in `__init__`**. All logic behind estimator parameters, like translating string arguments into functions, should be done in `fit`

Also it is expected that parameters with trailing `_` are **not to be set inside the `__init__` method**. All and only the public attributes set by `fit` have a trailing `_`. As a result the existence of parameters with trailing `_` is used to check if the estimator has been fitted.

Cloning

For use with the `model_selection` module, an estimator must support the `base.clone` function to replicate an estimator. This can be done by providing a `get_params` method. If `get_params` is present, then `clone(estimator)` will be an instance of `type(estimator)` on which `set_params` has been called with clones of the result of `estimator.get_params()`.

Objects that do not provide this method will be deep-copied (using the Python standard function `copy.deepcopy`) if `safe=False` is passed to `clone`.

Pipeline compatibility

For an estimator to be usable together with `pipeline.Pipeline` in any but the last step, it needs to provide a `fit` or `fit_transform` function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a `transform` function. There are no special requirements for the last step in a pipeline, except that it has a `fit` function. All `fit` and `fit_transform` functions must take arguments `X`, `y`, even if `y` is not used. Similarly, for `score` to be usable, the last step of the pipeline needs to have a `score` function that accepts an optional `y`.

Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in `model_selection.GridSearchCV` and `model_selection.cross_val_score` defaults to being stratified when used on a classifier, but not otherwise. Similarly, score for average precision that take a continuous prediction need to call `decision_function` for classifiers, but `predict` for regressors. This distinction between classifiers and regressors is implemented using the `_estimator_type` attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from `ClassifierMixin`, `RegressorMixin` or `ClusterMixin` will set the attribute automatically. When a meta-estimator needs to distinguish among estimator types, instead of checking `_estimator_type` directly, helpers like `base.is_classifier` should be used.

Specific models

Classifiers should accept `y` (target) arguments to `fit` that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of classes in a `classes_` attribute or property. The order of class labels in this attribute should match the order in which `predict_proba`, `predict_log_proba` and `decision_function` return their values. The easiest way to achieve this is to put:

```python
self.classes_, y = np.unique(y, return_inverse=True)
```
in `fit`. This returns a new `y` that contains class indexes, rather than labels, in the range `[0, n_classes)`.

A classifier's `predict` method should return arrays containing class labels from `classes_`. In a classifier that implements `decision_function`, this can be achieved with:

```python
def predict(self, X):
    D = self.decision_function(X)
    return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called `coef_`, and the independent term is stored in `intercept_`. `sklearn.linear_model._base` contains a few base classes and mixins that implement common linear model patterns.

The `sklearn.utils.multiclass` module contains useful functions for working with multiclass and multilabel problems.

**Estimator Tags**

_Warning:_ The estimator tags are experimental and the API is subject to change.

Scikit-learn introduced estimator tags in version 0.21. These are annotations of estimators that allow programmatic inspection of their capabilities, such as sparse matrix support, supported output types and supported methods. The estimator tags are a dictionary returned by the method `_get_tags()`. These tags are used by the common tests and the `sklearn.utils.estimator_checks.check_estimator` function to decide what tests to run and what input data is appropriate. Tags can depend on estimator parameters or even system architecture and can in general only be determined at runtime. The default values for the estimator tags are defined in the `BaseEstimator` class.

The current set of estimator tags are:

- **allow_nan** (default=False) whether the estimator supports data with missing values encoded as `np.NaN`
- **binary_only** (default=False) whether estimator supports binary classification but lacks multi-class classification support.
- **multilabel** (default=False) whether the estimator supports multilabel output
- **multioutput** (default=False) whether a regressor supports multi-target outputs or a classifier supports multi-class multi-output.
- **multioutput_only** (default=False) whether estimator supports only multi-output classification or regression.
- **no_validation** (default=False) whether the estimator skips input-validation. This is only meant for stateless and dummy transformers!
- **non_deterministic** (default=False) whether the estimator is not deterministic given a fixed `random_state`
- **pairwise** (default=False) This boolean attribute indicates whether the data (X) `fit` and similar methods consists of pairwise measures over samples rather than a feature representation for each sample. It is usually `True` where an estimator has a `metric` or `affinity` or `kernel` parameter with value `precomputed`. Its primary purpose is that when a `meta-estimator` extracts a sub-sample of data intended for a pairwise estimator, the data needs to be indexed on both axes, while other data is indexed only on the first axis.
- **preserves_dtype** (default=`[np.float64]`) applies only on transformers. It corresponds to the data types which will be preserved such that `X_trans.dtype` is the same as `X.dtype` after calling `transformer.transform(X)`. If this list is empty, then the transformer is not expected to preserve the data type. The first value in the list is considered as the default data type, corresponding to the data type of the output when the input data type is not going to be preserved.

8.2. Developing scikit-learn estimators
poor_score (default=False) whether the estimator fails to provide a “reasonable” test-set score, which currently for regression is an R2 of 0.5 on a subset of the boston housing dataset, and for classification an accuracy of 0.83 on make_blobs(n_samples=300, random_state=0). These datasets and values are based on current estimators in sklearn and might be replaced by something more systematic.

requires_fit (default=True) whether the estimator requires to be fitted before calling one of transform, predict, predict_proba, or decision_function.

requires_positive_X (default=False) whether the estimator requires positive X.

requires_y (default=False) whether the estimator requires y to be passed to fit, fit_predict or fit_transform methods. The tag is True for estimators inheriting from ~sklearn.base.RegressorMixim and ~sklearn.base.ClassifierMixim.

requires_positive_y (default=False) whether the estimator requires a positive y (only applicable for regression).

_skip_test (default=False) whether to skip common tests entirely. Don’t use this unless you have a very good reason.

_xfail_checks (default=False) dictionary {check_name: reason} of common checks that will be marked as XFAIL for pytest, when using parametrize_with_checks. These checks will be simply ignored and not run by check_estimator, but a SkipTestWarning will be raised. Don’t use this unless there is a very good reason for your estimator not to pass the check. Also note that the usage of this tag is highly subject to change because we are trying to make it more flexible: be prepared for breaking changes in the future.

stateless (default=False) whether the estimator needs access to data for fitting. Even though an estimator is stateless, it might still need a call to fit for initialization.

X_types (default=['2darray']) Supported input types for X as list of strings. Tests are currently only run if ‘2darray’ is contained in the list, signifying that the estimator takes continuous 2d numpy arrays as input. The default value is [’2darray’]. Other possible types are 'string', 'sparse', 'categorical', dict, '1dlabels' and '2dlabels'. The goal is that in the future the supported input type will determine the data used during testing, in particular for 'string', 'sparse' and 'categorical' data. For now, the test for sparse data do not make use of the 'sparse' tag.

To override the tags of a child class, one must define the _more_tags() method and return a dict with the desired tags, e.g:

```python
class MyMultiOutputEstimator(BaseEstimator):
    def _more_tags(self):
        return {'multioutput_only': True,
                'non_deterministic': True}
```

In addition to the tags, estimators also need to declare any non-optional parameters to __init__ in the _required_parameters class attribute, which is a list or tuple. If _required_parameters is only ['estimator'] or ['base_estimator'], then the estimator will be instantiated with an instance of LinearDiscriminantAnalysis (or RidgeRegression if the estimator is a regressor) in the tests. The choice of these two models is somewhat idiosyncratic but both should provide robust closed-form solutions.
8.2.3 Coding guidelines

The following are some guidelines on how new code should be written for inclusion in scikit-learn, and which may be appropriate to adopt in external projects. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.

Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in PEP8 that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: `n_samples` rather than `nsamples`.
- Avoid multiple statements on one line. Prefer a line return after a control flow statement (`if/for`).
- Use relative imports for references inside scikit-learn.
- Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if `sklearn.foo` exports a class or function that is implemented in `sklearn.foo.bar.baz`, the test should import it from `sklearn.foo`.
- Please don’t use `import *` in any case. It is considered harmful by the official Python recommendations. It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like `pyflakes` to automatically find bugs in scikit-learn.
- Use the numpy docstring standard in all your docstrings.

A good example of code that we like can be found here.

Input validation

The module `sklearn.utils` contains various functions for doing input validation and conversion. Sometimes, `np.asarray` suffices for validation; do not use `np.asanyarray` or `np.atleast_2d`, since those let NumPy’s `np.matrix` through, which has a different API (e.g., `*` means dot product on `np.matrix`, but Hadamard product on `np.ndarray`).

In other cases, be sure to call `check_array` on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which `scipy.sparse` matrices must be accepted.

For more information, refer to the Utilities for Developers page.

Random Numbers

If your code depends on a random number generator, do not use `numpy.random.random()` or similar routines. To ensure repeatability in error checking, the routine should accept a keyword `random_state` and use this to construct a `numpy.random.RandomState` object. See `sklearn.utils.check_random_state` in Utilities for Developers.

Here’s a simple example of code using some of the above guidelines:

```
from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
    """Choose a random point from X."

    Parameters
```
X : array-like of shape (n_samples, n_features)
   An array representing the data.
random_state : int or RandomState instance, default=0
   The seed of the pseudo random number generator that selects a
   random sample. Pass an int for reproducible output across multiple
   function calls.
   See :term:`Glossary <random_state>`.

Returns
-------
x : ndarray of shape (n_features,)
   A random point selected from X.

X = check_array(X)
random_state = check_random_state(random_state)
i = random_state.randint(X.shape[0])
return X[i]

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.

First off, the estimator should take a random_state argument to its __init__ with a default value of None. It should store that argument’s value, unmodified, in an attribute random_state. fit can call check_random_state on that attribute to get an actual random number generator. If, for some reason, randomness is needed after fit, the RNG should be stored in an attribute random_state_. The following example should make this clear:

class GaussianNoise(BaseEstimator, TransformerMixin):
   """This estimator ignores its input and returns random Gaussian noise.
   It also does not adhere to all scikit-learn conventions, but showcases how to handle randomness."
   ""
   def __init__(self, n_components=100, random_state=None):
      self.random_state = random_state
      self.n_components = n_components

   # the arguments are ignored anyway, so we make them optional
   def fit(self, X=None, y=None):
      self.random_state_ = check_random_state(self.random_state)

   def transform(self, X):
      n_samples = X.shape[0]
      return self.random_state_.randn(n_samples, self.n_components)

The reason for this setup is reproducibility: when an estimator is fit twice to the same data, it should produce an identical model both times, hence the validation in fit, not __init__.
8.3 Developers’ Tips and Tricks

8.3.1 Productivity and sanity-preserving tips

In this section we gather some useful advice and tools that may increase your quality-of-life when reviewing pull requests, running unit tests, and so forth. Some of these tricks consist of userscripts that require a browser extension such as TamperMonkey or GreaseMonkey; to set up userscripts you must have one of these extensions installed, enabled and running. We provide userscripts as GitHub gists; to install them, click on the “Raw” button on the gist page.

Folding and unfolding outdated diffs on pull requests

GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while. This userscript provides a shortcut (Control-Alt-P at the time of writing but look at the code to be sure) to unfold all such hidden discussions at once, so you can catch up.

Checking out pull requests as remote-tracking branches

In your local fork, add to your .git/config, under the [remote "upstream"] heading, the line:

```bash
fetch = +refs/pull/*/head:refs/remotes/upstream/pr/*
```

You may then use `git checkout pr/PR_NUMBER` to navigate to the code of the pull-request with the given number. (Read more in this gist.)

Display code coverage in pull requests

To overlay the code coverage reports generated by the CodeCov continuous integration, consider this browser extension. The coverage of each line will be displayed as a color background behind the line number.

Useful pytest aliases and flags

The full test suite takes fairly long to run. For faster iterations, it is possibly to select a subset of tests using pytest selectors. In particular, one can run a single test based on its node ID:

```bash
pytest -v sklearn/linear_model/tests/test_logistic.py::test_sparsify
```

or use the `-k pytest` parameter to select tests based on their name. For instance,: 

```bash
pytest sklearn/tests/test_common.py -v -k LogisticRegression
```

will run all `common tests` for the `LogisticRegression` estimator.

When a unit test fails, the following tricks can make debugging easier:

1. The command line argument `pytest -l` instructs pytest to print the local variables when a failure occurs.
2. The argument `pytest --pdb` drops into the Python debugger on failure. To instead drop into the rich IPython debugger `ipdb`, you may set up a shell alias to:

```bash
pytest --pdbcls=IPython.terminal.debugger:TerminalPdb --capture no
```
Other pytest options that may become useful include:

- `-x` which exits on the first failed test
- `--lf` to rerun the tests that failed on the previous run
- `--ff` to rerun all previous tests, running the ones that failed first
- `-s` so that pytest does not capture the output of `print()` statements
- `--tb=short` or `--tb=line` to control the length of the logs
- `--runxfail` also run tests marked as a known failure (XFAIL) and report errors.

Since our continuous integration tests will error if `FutureWarning` isn’t properly caught, it is also recommended to run pytest along with the `--Werror::FutureWarning` flag.

**Standard replies for reviewing**

It may be helpful to store some of these in GitHub’s saved replies for reviewing:

**Issue: Usage questions**

You are asking a usage question. The issue tracker is for bugs and new features. For usage questions, it is recommended to try [Stack Overflow](https://stackoverflow.com/questions/tagged/scikit-learn) or [the Mailing List](https://mail.python.org/mailman/listinfo/scikit-learn).

Unfortunately, we need to close this issue as this issue tracker is a communication tool used for the development of scikit-learn. The additional activity created by usage questions crowds it too much and impedes this development. The conversation can continue here, however there is no guarantee that is will receive attention from core developers.

**Issue: You’re welcome to update the docs**

Please feel free to offer a pull request updating the documentation if you feel it could be improved.

**Issue: Self-contained example for bug**

Please provide [self-contained example code](https://stackoverflow.com/help/mcve), including imports and data (if possible), so that other contributors can just run it and reproduce your issue. Ideally your example code should be minimal.

**Issue: Software versions**

To help diagnose your issue, please paste the output of:

```
```
import sklearn; sklearn.show_versions()
```

Thanks.

**Issue: Code blocks**

Readability can be greatly improved if you [format](https://help.github.com/articles/creating-and-highlighting-code-blocks/) your code snippets and complete error messages appropriately. For example:
```
```
8.3.2 Debugging memory errors in Cython with valgrind

While python/numpy’s built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn is written in cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is valgrind.

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install valgrind on your system.
2. Download the python valgrind suppression file: valgrind-python.supp.
3. Follow the directions in the README.valgrind file to customize your python suppressions. If you don’t, you will have spurious output coming related to the python interpreter instead of your own code.

4. Run valgrind as follows:

   `valgrind --suppressions=valgrind-python.supp python my_test_script.py`

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the valgrind web site.

### 8.3.3 Building and testing for the ARM64 platform on a x86_64 machine

ARM-based machines are a popular target for mobile, edge or other low-energy deployments (including in the cloud, for instance on Scaleway or AWS Graviton).

Here are instructions to setup a local dev environment to reproduce ARM-specific bugs or test failures on a x86_64 host laptop or workstation. This is based on QEMU user mode emulation using docker for convenience (see https://github.com/multiarch/qemu-user-static).

**Note:** The following instructions are illustrated for ARM64 but they also apply to ppc64le, after changing the Docker image and Miniforge paths appropriately.

Prepare a folder on the host filesystem and download the necessary tools and source code:

```bash
mkdir arm64
pushd arm64
wget https://github.com/conda-forge/miniforge/releases/latest/download/Miniforge3-Linux-aarch64.sh
git clone https://github.com/scikit-learn/scikit-learn.git
```

Use docker to install QEMU user mode and run an ARM64v8 container with access to your shared folder under the /io mount point:

```bash
docker run --rm --privileged multiarch/qemu-user-static --reset -p yes
docker run -v`pwd`:/io --rm -it arm64v8/ubuntu /bin/bash
```

In the container, install miniforge3 for the ARM64 (a.k.a. aarch64) architecture:

```bash
bash Miniforge3-Linux-aarch64.sh
# Choose to install miniforge3 under: `/io/miniforge3`
```

Whenever you restart a new container, you will need to reinit the conda env previously installed under /io/miniforge3:

```bash
/io/miniforge3/bin/conda init
source /root/.bashrc
```

as the /root home folder is part of the ephemeral docker container. Every file or directory stored under /io is persistent on the other hand.

### 8.3. Developers’ Tips and Tricks
You can then build scikit-learn as usual (you will need to install compiler tools and dependencies using apt or conda as usual). Building scikit-learn takes a lot of time because of the emulation layer, however it needs to be done only once if you put the scikit-learn folder under the /io mount point.

Then use pytest to run only the tests of the module you are interested in debugging.

8.4 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in sklearn.utils, and include tools in a number of categories. All the following functions and classes are in the module sklearn.utils.

**Warning:** These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.

8.4.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- **assert_all_finite**: Throw an error if array contains NaNs or Infs.
- **as_float_array**: convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- **check_array**: check that input is a 2D array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1D or N-dimensional arrays. Calls assert_all_finite by default.
- **check_X_y**: check that X and y have consistent length, calls check_array on X, and column_or_1d on y. For multilabel classification or multitarget regression, specify multi_output=True, in which case check_array will be called on y.
- **indexable**: check that all input arrays have consistent length and can be sliced or indexed using safe_index. This is used to validate input for cross-validation.
- **validation.check_memory** checks that input is joblib.Memory-like, which means that it can be converted into a sklearn.utils.Memory instance (typically a str denoting the cachedir) or has the same interface.

If your code relies on a random number generator, it should never use functions like numpy.random.random or numpy.random.normal. This approach can lead to repeatability issues in unit tests. Instead, a numpy.random.RandomState object should be used, which is built from a random_state argument passed to the class or function. The function check_random_state, below, can then be used to create a random number generator object.

- **check_random_state**: create a np.random.RandomState object from a parameter random_state.
  - If random_state is None or np.random, then a randomly-initialized RandomState object is returned.
  - If random_state is an integer, then it is used to seed a new RandomState object.
  - If random_state is a RandomState object, then it is passed through.

For example:
When developing your own scikit-learn compatible estimator, the following helpers are available:

- `validation.check_is_fitted`: check that the estimator has been fitted before calling `transform`, `predict`, or similar methods. This helper allows to raise a standardized error message across estimator.
- `validation.has_fit_parameter`: check that a given parameter is supported in the `fit` method of a given estimator.

### 8.4.2 Efficient Linear Algebra & Array Operations

- `extmath.randomized_range_finder`: construct an orthonormal matrix whose range approximates the range of the input. This is used in `extmath.randomized_svd`, below.
- `extmath.randomized_svd`: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.
- `arrayfuncs.cholesky_delete`: (used in `lars_path`) Remove an item from a cholesky factorization.
- `arrayfuncs.min_pos`: (used in `sklearn.linear_model.least_angle`) Find the minimum of the positive values within an array.
- `extmath.fast_logdet`: efficiently compute the log of the determinant of a matrix.
- `extmath.density`: efficiently compute the density of a sparse vector
- `extmath.safe_sparse_dot`: dot product which will correctly handle `scipy.sparse` inputs. If the inputs are dense, it is equivalent to `numpy.dot`.
- `extmath.weighted_mode`: an extension of `scipy.stats.mode` which allows each item to have a real-valued weight.
- `resample`: Resample arrays or sparse matrices in a consistent way. used in `shuffle`, below.
- `shuffle`: Shuffle arrays or sparse matrices in a consistent way. Used in `k_means`.

### 8.4.3 Efficient Random Sampling

- `random.sample_without_replacement`: implements efficient algorithms for sampling `n_samples` integers from a population of size `n_population` without replacement.

### 8.4.4 Efficient Routines for Sparse Matrices

The `sklearn.utils.sparsefuncs` cython module hosts compiled extensions to efficiently process `scipy.sparse` data.

- `sparsefuncs.mean_variance_axis`: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in `KMeans`.
- `sparsefuncs_fast.inplace_csr_row_normalize_l1` and `sparsefuncs_fast.inplace_csr_row_normalize_l2`: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in `Normalizer`.

---

### 8.4. Utilities for Developers 2823
• `sparsefuncs.inplace_csr_column_scale`: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in `StandardScaler`.

8.4.5 Graph Routines

• `graph.single_source_shortest_path_length`: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from `networkx`. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra’s algorithm from `graph_shortest_path`.

• `graph_shortest_path.graph_shortest_path`: (used in Isomap) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra’s algorithm are available. The algorithm is most efficient when the connectivity matrix is a `scipy.sparse.csr_matrix`.

8.4.6 Testing Functions

• `all_estimators`: returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

8.4.7 Multiclass and multilabel utility function

• `multiclass.is_multilabel`: Helper function to check if the task is a multi-label classification one.

• `multiclass.unique_labels`: Helper function to extract an ordered array of unique labels from different formats of target.

8.4.8 Helper Functions

• `gen_even_slices`: generator to create \(n\)-packs of slices going up to \(n\). Used in `dict_learning` and `k_means`.

• `safe_mask`: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).

• `safe_sqr`: Helper function for unified squaring (\(\ast \ast 2\)) of array-likes, matrices and sparse matrices.

8.4.9 Hash Functions

• `murmurhash3_32` provides a python wrapper for the MurmurHash3_x86_32 C++ non-cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```python
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True

>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```
The `sklearn.utils.murmurhash` module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.

### 8.4.10 Warnings and Exceptions

- **deprecated**: Decorator to mark a function or class as deprecated.
- **ConvergenceWarning**: Custom warning to catch convergence problems. Used in `sklearn.covariance.graphical_lasso`.

### 8.5 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

**Note:** While it is always useful to profile your code so as to check performance assumptions, it is also highly recommended to review the literature to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple algorithmic tricks, or by using another algorithm altogether that is better suited to the problem.

The section *A simple algorithmic trick: warm restarts* gives an example of such a trick.

### 8.5.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the readability of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to start implementing it in Python using Numpy and Scipy by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to replace any nested for loops by calls to equivalent Numpy array methods. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It’s generally a good idea to consider NumPy and SciPy performance tips: https://scipy.github.io/old-wiki/pages/PerformanceTips

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. **Profile** the Python implementation to find the main bottleneck and isolate it in a dedicated module level function. This function will be reimplemented as a compiled extension module.

2. If there exists a well maintained BSD or MIT C/C++ implementation of the same algorithm that is not too big, you can write a Cython wrapper for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes `svm.LinearSVC`, `svm.SVC` and `linear_model.LogisticRegression` (wrappers for liblinear and libsvm).

3. Otherwise, write an optimized version of your Python function using Cython directly. This strategy is used for the `linear_model.ElasticNet` and `linear_model.SGDClassifier` classes for instance.

4. **Move the Python version of the function in the tests** and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.
5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have **coarse grained parallelism** that is amenable to **multi-processing** by using the joblib.Parallel class. When using Cython, use either

```
$ python setup.py build_ext -i $ python setup.py install
```

to generate C files. You are responsible for adding .c/.cpp extensions along with build parameters in each submodule setup.py.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, Scipy and C/C++ compiler.

### 8.5.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of scikit-learn. Let us setup a new IPython session and load the digits dataset and as in the Recognizing hand-written digits example:

```python
In [1]: from sklearn.decomposition import NMF
In [2]: from sklearn.datasets import load_digits
In [3]: X, _ = load_digits(return_X_y=True)
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```python
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the %prun magic command:

```python
In [5]: %prun -l nmf.py NMF(n_components=16, tol=1e-2).fit(X)
```

```
14496 function calls in 1.682 CPU seconds
Ordered by: internal time
List reduced from 90 to 9 due to restriction '<nmf.py'>
```

```
ncalls  tottime  percall  cumtime  percall filename:lineno(function)
36     0.609    0.017    1.499    0.042 nmf.py:151(_nls_subproblem)
1263   0.157    0.000    0.157    0.000 nmf.py:18(_pos)
     1    0.053    0.053    1.681    1.681 nmf.py:352(fit_transform)
     1    0.006    0.006    0.047    0.047 nmf.py:42(_initialize_nmf)
     1    0.000    0.000    0.010    0.010 nmf.py:36(_sparseness)
     1    0.000    0.000    0.000    0.000 nmf.py:23(_neg)
     1    0.000    0.000    0.000    0.000 nmf.py:337(__init__)  
     1    0.000    0.000    1.681    1.681 nmf.py:461(fit)
```

The *tottime* column is the most interesting: it gives to total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the *cumtime* column.

Note the use of the -l nmf.py that restricts the output to lines that contains the “nmf.py” string. This is useful to have a quick look at the hotspot of the nmf Python module it-self ignoring anything else.
Here is the beginning of the output of the same command without the -l nmf.py filter:

```
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)
    16159 function calls in 1.840 CPU seconds

Ordered by: internal time

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
       2833  0.653    0.000  0.653    0.000 {numpy.core._dotblas.dot}
           46  0.651  0.014   1.636  0.036 nmf.py:151(_nls_subproblem)
          1397  0.171    0.000  0.171    0.000 nmf.py:18(_pos)
          2780  0.167    0.000  0.167    0.000 {method 'sum' of 'numpy.ndarray'←}
   1 objects
1  0.064  0.064  1.840  1.840 nmf.py:352(fit_transform)
  1542  0.043    0.000  0.043    0.000 {method 'flatten' of 'numpy.ndarray'←}
   337  0.019    0.000  0.019    0.000 {method 'all' of 'numpy.ndarray'←}
   2734  0.011    0.000  0.181  0.000 fromnumeric.py:1185(sum)
    2  0.010  0.005  0.010  0.005 {numpy.linalg.lapack_lite.dgesdd}
    748  0.009    0.000  0.065  0.000 nmf.py:28(norm)
...
```

The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably no huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by algorithmic improvements in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing them rather than trying to optimize their implementation).

It is however still interesting to check what’s happening inside the _nls_subproblem function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install line_profiler and wire it to IPython:

```
$ pip install line_profiler

• Under IPython 0.13+, first create a configuration profile:
  $ ipython profile create

Then register the line_profiler extension in ~/.ipython/profile_default/ipython_config.py:

```python
c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')
```

This will register the %lprun magic command in the IPython terminal application and the other frontends such as qtconsole and notebook.

Now restart IPython and let us use this new toy:

```
In [1]: from sklearn.datasets import load_digits
In [2]: from sklearn.decomposition import NMF
   ... : from sklearn.decomposition._nmf import _nls_subproblem
```

(continues on next page)
In [3]: X, _ = load_digits(return_X_y=True)

In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)

Timer unit: 1e-06 s

File: sklearn/decomposition/nmf.py
Function: _nls_subproblem at line 137
Total time: 1.73153 s

Line #   Hits  Time  Per Hit  % Time  Line Contents
---------------------------------------------------------------
137     def _nls_subproblem(V, W, H_init, tol, max_iter):
       138     """Non-negative least square solver
       139     
       140     # values justified in the paper
       141     alpha = 1
       142     beta = 0.1
       143     for n_iter in range(1, max_iter):
       144     grad = np.dot(WtW, H) - WtV
       145     # Hn = np.where(Hn > 0, Hn, 0)
       146     Hn = _pos(Hn)
       147     d = Hn - H
       148     gradd = np.sum(grad * d)
       149     dQd = np.sum(np.dot(WtW, d) * d)

By looking at the top values of the % Time column it is really easy to pin-point the most expensive expressions that would deserve additional care.
8.5.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of `memory_profiler`. First, install the latest version:

```
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to `line_profiler`.

- **Under IPython 0.11+**, first create a configuration profile:

  ````
  $ ipython profile create
  Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:
  ````
  ```
  c.TerminallIPythonApp.extensions.append('memory_profiler')
  c.InteractiveShellApp.extensions.append('memory_profiler')
  ```

  This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as qtconsole and notebook.

  `%mprun` is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to `%lprun`, discussed in the previous section. For example, from the `memory_profiler` examples directory:

  ````
  In [1]: from example import my_func
  In [2]: %mprun -f my_func my_func()
  Filename: example.py
  Line #  Mem usage  Increment  Line Contents
  -----------------------------------------------
  3       @profile
  4       5.97 MB  0.00 MB def my_func():
  5       13.61 MB 7.64 MB a = [1] * (10 ** 6)
  6       166.20 MB 152.59 MB b = [2] * (2 * 10 ** 7)
  7       13.61 MB -152.59 MB del b
  8       13.61 MB 0.00 MB return a
  ```

  Another useful magic that `memory_profiler` defines is `%memit`, which is analogous to `%timeit`. It can be used as follows:

  ````
  In [1]: import numpy as np
  In [2]: %memit np.zeros(1e7)
  maximum of 3: 76.402344 MB per loop
  ```

  For more details, see the docstrings of the magics, using `%memit?` and `%mprun?`. 
8.5.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation (e.g. for loops over vector components, nested evaluation of conditional expression, scalar arithmetic…), it is probably adequate to extract the hotspot portion of the code as a standalone function in a .pyx file, add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module.

The official documentation available at http://docs.cython.org/ contains a tutorial and reference guide for developing such a module. In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls…

- https://www.youtube.com/watch?v=gMvkiQ-gOW8

Using OpenMP

Since scikit-learn can be built without OpenMP, it’s necessary to protect each direct call to OpenMP. This can be done using the following syntax:

```python
# importing OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
    cimport openmp

# calling OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
    max_threads = openmp.omp_get_max_threads()
ELSE:
    max_threads = 1
```

Note: Protecting the parallel loop, prange, is already done by cython.

8.5.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default Python profiler is useless: we need a dedicated tool to introspect what’s happening inside the compiled extension itself.

Using yep and gperftools

Easy profiling without special compilation options use yep:

- https://pypi.org/project/yep/
- http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions
Using gprof

In order to profile compiled Python extensions one could use gprof after having recompiled the project with gcc -pg and using the python-db variant of the interpreter on debian / ubuntu: however this approach requires to also have numpy and scipy recompiled with -pg which is rather complicated to get working.

Fortunately there exist two alternative profilers that don’t require you to recompile everything.

Using valgrind / callgrind / kcachegrind

kcachegrind

yep can be used to create a profiling report. kcachegrind provides a graphical environment to visualize this report:

```bash
# Run yep to profile some python script
python -m yep -c my_file.py

# open my_file.py.callgrind with kcachegrind
kcachegrind my_file.py.prof
```

Note: yep can be executed with the argument --lines or -l to compile a profiling report ‘line by line’.

8.5.6 Multi-core parallelism using joblib.Parallel

See joblib documentation

8.5.7 A simple algorithmic trick: warm restarts

See the glossary entry for warm_start

8.6 Installing the development version of scikit-learn

This section introduces how to install the master branch of scikit-learn. This can be done by either installing a nightly build or building from source.

8.6.1 Installing nightly builds

The continuous integration servers of the scikit-learn project build, test and upload wheel packages for the most recent Python version on a nightly basis.

Installing a nightly build is the quickest way to:

- try a new feature that will be shipped in the next release (that is, a feature from a pull-request that was recently merged to the master branch);
- check whether a bug you encountered has been fixed since the last release.

```bash
pip install --pre --extra-index https://pypi.anaconda.org/scipy-wheels-nightly/simple --scikit-learn
```
8.6.2 Building from source

Building from source is required to work on a contribution (bug fix, new feature, code or documentation improvement).

1. Use Git to check out the latest source from the scikit-learn repository on Github:

```bash
git clone git://github.com/scikit-learn/scikit-learn.git  # add --depth 1 if your connection is slow
cd scikit-learn
```

If you plan on submitting a pull-request, you should clone from your fork instead.

2. Install a compiler with OpenMP support for your platform. See instructions for Windows, macOS, Linux and FreeBSD.

3. Optional (but recommended): create and activate a dedicated virtualenv or conda environment.

4. Install Cython and build the project with pip in Editable mode:

```bash
pip install cython
pip install --verbose --no-build-isolation --editable .
```

5. Check that the installed scikit-learn has a version number ending with .dev0:

```bash
python -c "import sklearn; sklearn.show_versions()"
```

6. Please refer to the Developer’s Guide and Useful pytest aliases and flags to run the tests on the module of your choice.

Note: You will have to run the `pip install --no-build-isolation --editable .` command every time the source code of a Cython file is updated (ending in .pyx or .pxd). Use the `--no-build-isolation` flag to avoid compiling the whole project each time, only the files you have modified.

Dependencies

Runtime dependencies

Scikit-learn requires the following dependencies both at build time and at runtime:

- Python (>= 3.6),
- NumPy (>= 1.13.3),
- SciPy (>= 0.19.1),
- Joblib (>= 0.11),
- threadpoolctl (>= 2.0.0).

Those dependencies are automatically installed by pip if they were missing when building scikit-learn from source.

Note: For running on PyPy, PyPy3-v5.10+, Numpy 1.14.0+, and scipy 1.1.0+ are required. For PyPy, only installation instructions with pip apply.
Build dependencies

Building Scikit-learn also requires:

- Cython >= 0.28.5
- A C/C++ compiler and a matching OpenMP runtime library. See the platform system specific instructions for more details.

Note: If OpenMP is not supported by the compiler, the build will be done with OpenMP functionalities disabled. This is not recommended since it will force some estimators to run in sequential mode instead of leveraging thread-based parallelism. Setting the SKLEARN_FAIL_NO_OPENMP environment variable (before cythonization) will force the build to fail if OpenMP is not supported.

Since version 0.21, scikit-learn automatically detects and use the linear algebra library used by SciPy at runtime. Scikit-learn has therefore no build dependency on BLAS/LAPACK implementations such as OpenBlas, Atlas, Blis or MKL.

Test dependencies

Running tests requires:

- pytest >= 5.0.1

Some tests also require pandas.

Building a specific version from a tag

If you want to build a stable version, you can git checkout <VERSION> to get the code for that particular version, or download an zip archive of the version from github.

Editable mode

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. Therefore it is recommended that you install in with the pip install --no-build-isolation --editable . command, which allows you to edit the code in-place. This builds the extension in place and creates a link to the development directory (see the pip docs).

This is fundamentally similar to using the command python setup.py develop (see the setupdoc docs). It is however preferred to use pip.

On Unix-like systems, you can equivalently type make in from the top-level folder. Have a look at the Makefile for additional utilities.
8.6.3 Platform-specific instructions

Here are instructions to install a working C/C++ compiler with OpenMP support to build scikit-learn Cython extensions for each supported platform.

Windows

Secondly, find out if you are running 64-bit or 32-bit Python. The building command depends on the architecture of the Python interpreter. You can check the architecture by running the following in cmd or powershell console:

```
python -c "import struct; print(struct.calcsize('P') * 8)"
```

For 64-bit Python, configure the build environment with:

```
SET DISTUTILS_USE_SDK=1
"C:\Program Files (x86)\Microsoft Visual Studio\2019\BuildTools\VC\Auxiliary\Build\vcvarsall.bat" x64
```

Replace x64 by x86 to build for 32-bit Python.

Please be aware that the path above might be different from user to user. The aim is to point to the “vcvarsall.bat” file that will set the necessary environment variables in the current command prompt.

Finally, build scikit-learn from this command prompt:

```
pip install --verbose --no-build-isolation --editable .
```

macOS

The default C compiler on macOS, Apple clang (confusingly aliased as /usr/bin/gcc), does not directly support OpenMP. We present two alternatives to enable OpenMP support:

- either install conda-forge::compilers with conda;
- or install libomp with Homebrew to extend the default Apple clang compiler.

macOS compilers from conda-forge

If you use the conda package manager (version >= 4.7), you can install the compilers meta-package from the conda-forge channel, which provides OpenMP-enabled C/C++ compilers based on the llvm toolchain.

First install the macOS command line tools:

```
xcode-select --install
```

It is recommended to use a dedicated conda environment to build scikit-learn from source:
conda create -n sklearn-dev python numpy scipy cython joblib pytest 
conda activate sklearn-dev
make clean
pip install --verbose --no-build-isolation --editable .

**Note:** If you get any conflicting dependency error message, try commenting out any custom conda configuration in the `$HOME/.condarc` file. In particular the `channel_priority: strict` directive is known to cause problems for this setup.

You can check that the custom compilers are properly installed from conda forge using the following command:

```bash
conda list
```

which should include `compilers` and `llvm-openmp`.

The compilers meta-package will automatically set custom environment variables:

```bash
echo $CC
echo $CXX
echo $CFLAGS
echo $CXXFLAGS
echo $LDFLAGS
```

They point to files and folders from your `sklearn-dev` conda environment (in particular in the `bin/`, `include/` and `lib/` subfolders). For instance `–L/path/to/conda/envs/sklearn-dev/lib` should appear in `LDFLAGS`.

In the log, you should see the compiled extension being built with the clang and clang++ compilers installed by conda with the `-fopenmp` command line flag.

### macOS compilers from Homebrew

Another solution is to enable OpenMP support for the clang compiler shipped by default on macOS.

First install the macOS command line tools:

```bash
xcode-select --install
```

Install the Homebrew package manager for macOS.

Install the LLVM OpenMP library:

```bash
brew install libomp
```

Set the following environment variables:

```bash
export CC=/usr/bin/clang
export CXX=/usr/bin/clang++
export CPPFLAGS="-I/usr/local/opt/libomp/include"
export CFLAGS="-I/usr/local/opt/libomp/include"
export CXXFLAGS="-I/usr/local/opt/libomp/include"
```

Finally, build scikit-learn in verbose mode (to check for the presence of the `-fopenmp` flag in the compiler commands):

```bash
pip install --verbose --no-build-isolation --editable .
```
Linux

Linux compilers from the system

Installing scikit-learn from source without using conda requires you to have installed the scikit-learn Python development headers and a working C/C++ compiler with OpenMP support (typically the GCC toolchain).

Install build dependencies for Debian-based operating systems, e.g. Ubuntu:

```
sudo apt-get install build-essential python3-dev python3-pip
```

then proceed as usual:

```
pip3 install cython
pip3 install --verbose --editable .
```

Cython and the pre-compiled wheels for the runtime dependencies (numpy, scipy and joblib) should automatically be installed in `$HOME/.local/lib/pythonX.Y/site-packages`. Alternatively you can run the above commands from a virtualenv or a conda environment to get full isolation from the Python packages installed via the system package. When using an isolated environment, `pip3` should be replaced by `pip` in the above commands.

When precompiled wheels of the runtime dependencies are not available for your architecture (e.g. ARM), you can install the system versions:

```
sudo apt-get install cython3 python3-numpy python3-scipy
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```
sudo yum -y install gcc gcc-c++ python3-devel numpy scipy
```

Linux compilers from conda-forge

Alternatively, install a recent version of the GNU C Compiler toolchain (GCC) in the user folder using conda:

```
conda create -n sklearn-dev numpy scipy joblib cython conda-forge::compilers
conda activate sklearn-dev
pip install --verbose --no-build-isolation --editable .
```

FreeBSD

The clang compiler included in FreeBSD 12.0 and 11.2 base systems does not include OpenMP support. You need to install the openmp library from packages (or ports):

```
sudo pkg install openmp
```

This will install header files in `/usr/local/include` and libs in `/usr/local/lib`. Since these directories are not searched by default, you can set the environment variables to these locations:
Finally, build the package using the standard command:

```
pip install --verbose --no-build-isolation --editable .
```

For the upcoming FreeBSD 12.1 and 11.3 versions, OpenMP will be included in the base system and these steps will not be necessary.

### 8.6.4 Alternative compilers

The command:

```
pip install --verbose --editable .
```

will build scikit-learn using your default C/C++ compiler. If you want to build scikit-learn with another compiler handled by distutils or by numpy.distutils, use the following command:

```
python setup.py build_ext --compiler=<compiler> -i build_clib --compiler=<compiler>
```

To see the list of available compilers run:

```
python setup.py build_ext --help-compiler
```

If your compiler is not listed here, you can specify it via the `CC` and `LDSHARED` environment variables (does not work on windows):

```
CC=<compiler> LDSHARED="<compiler> -shared" python setup.py build_ext -i
```

### Building with Intel C Compiler (ICC) using oneAPI on Linux

Intel provides access to all of its oneAPI toolkits and packages through a public APT repository. First you need to get and install the public key of this repository:

```
sudo apt-key add GPG-PUB-KEY-INTEL-SW-PRODUCTS-2023.PUB
rm GPG-PUB-KEY-INTEL-SW-PRODUCTS-2023.PUB
```

Then, add the oneAPI repository to your APT repositories:

```
sudo add-apt-repository "deb https://apt.repos.intel.com/oneapi all main"
sudo apt-get update
```

Install ICC, packaged under the name `intel-oneapi-icc`:

```
sudo apt-get install intel-oneapi-icc
```

Before using ICC, you need to set up environment variables:

```
source /opt/intel/inteloneapi/setvars.sh
```

Finally, you can build scikit-learn. For example on Linux x86_64:
8.7 Bug triaging and issue curation

The issue tracker is important to the communication in the project: it helps developers identify major projects to work on, as well as to discuss priorities. For this reason, it is important to curate it, adding labels to issues and closing issues that are not necessary.

8.7.1 Working on issues to improve them

Improving issues increases their chances of being successfully resolved. Guidelines on submitting good issues can be found here. A third party can give useful feedback or even add comments on the issue. The following actions are typically useful:

- documenting issues that are missing elements to reproduce the problem such as code samples
- suggesting better use of code formatting
- suggesting to reformulate the title and description to make them more explicit about the problem to be solved
- linking to related issues or discussions while briefly describing how they are related, for instance “See also #xyz for a similar attempt at this” or “See also #xyz where the same thing happened in SomeEstimator” provides context and helps the discussion.

Fruitful discussions

Online discussions may be harder than it seems at first glance, in particular given that a person new to open-source may have a very different understanding of the process than a seasonned maintainer.

Overall, it is useful to stay positive and assume good will. The following article explores how to lead online discussions in the context of open source.

8.7.2 Working on PRs to help review

Reviewing code is also encouraged. Contributors and users are welcome to participate to the review process following our review guidelines.

8.7.3 Triaging operations for members of the core and triage teams

In addition to the above, members of the core team and the triage team can do the following important tasks:

- Update labels for issues and PRs: see the list of the available github labels.
- Determine if a PR must be relabeled as stalled or needs help (this is typically very important in the context of sprints, where the risk is to create many unfinished PRs)
- Triage issues:
  - close usage questions and politely point the reporter to use Stack Overflow instead.
  - close duplicate issues, after checking that they are indeed duplicate. Ideally, the original submitter moves the discussion to the older, duplicate issue
– close issues that cannot be replicated, after leaving time (at least a week) to add extra information

**Saved replies** are useful to gain time and yet be welcoming and polite when triaging.

See the github description for roles in the organization.

---

### Closing issues: a tough call

When uncertain on whether an issue should be closed or not, it is best to strive for consensus with the original poster, and possibly to seek relevant expertise. However, when the issue is a usage question, or when it has been considered as unclear for many years it should be closed.

---

### 8.7.4 A typical workflow for triaging issues

The following workflow\(^1\) is a good way to approach issue triaging:

1. Thank the reporter for opening an issue
   
   The issue tracker is many people’s first interaction with the scikit-learn project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.
   
2. Is this a usage question? If so close it with a polite message ([here is an example](#)).
3. Is the necessary information provided?
   
   If crucial information (like the version of scikit-learn used), is missing feel free to ask for that and label the issue with “Needs info”.
   
4. Is this a duplicate issue?
   
   We have many open issues. If a new issue seems to be a duplicate, point to the original issue. If it is a clear duplicate, or consensus is that it is redundant, close it. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.
   
   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.
   
5. Make sure that the title accurately reflects the issue. If you have the necessary permissions edit it yourself if it's not clear.
6. Is the issue minimal and reproducible?
   
   For bug reports, we ask that the reporter provide a minimal reproducible example. See [this useful post](#) by Matthew Rocklin for a good explanation. If the example is not reproducible, or if it’s clearly not minimal, feel free to ask the reporter if they can provide and example or simplify the provided one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself.
   
   If a reproducible example is provided, but you see a simplification, add your simpler reproducible example.
   
7. Add the relevant labels, such as “Documentation” when the issue is about documentation, “Bug” if it is clearly a bug, “Enhancement” if it is an enhancement request, . . .
   
   If the issue is clearly defined and the fix seems relatively straightforward, label the issue as “Good first issue”.
   
   An additional useful step can be to tag the corresponding module e.g. `sklearn.linear_models` when relevant.

8.7. Bug triaging and issue curation 2839
8.8 Maintainer / core-developer information

8.8.1 Releasing

This section is about preparing a major release, incrementing the minor version, or a bug fix release incrementing the patch version. Our convention is that we release one or more release candidates (0.RRrcN) before releasing the final distributions. We follow the PEP101 to indicate release candidates, post, and minor releases.

Before a release

1. Update authors table:

   ```
   $ cd build_tools; make authors; cd ..
   ```

   and commit. This is only needed if the authors have changed since the last release. This step is sometimes done independent of the release. This updates the maintainer list and is not the contributor list for the release.

2. Confirm any blockers tagged for the milestone are resolved, and that other issues tagged for the milestone can be postponed.

3. Ensure the change log and commits correspond (within reason!), and that the change log is reasonably well curated. Some tools for these tasks include:

   • Maint `maint_tools/sort_whats_new.py` can put what’s new entries into sections. It’s not perfect, and requires manual checking of the changes. If the what’s new list is well curated, it may not be necessary.

   • The `maint_tools/whats_missing.sh` script may be used to identify pull requests that were merged but likely missing from What’s New.

4. Make sure the deprecations, FIXME and TODOs tagged for the release have been taken care of.

Permissions

The release manager requires a set of permissions on top of the usual permissions given to maintainers, which includes:

- `maintainer` role on scikit-learn projects on pypi.org and test.pypi.org, separately.
- become a member of the scikit-learn team on conda-forge by editing the recipe/meta.yaml file on https://github.com/conda-forge/scikit-learn-feedstock
- `maintainer` on https://github.com/MacPython/scikit-learn-wheels

Preparing a release PR

Releasing the first RC of e.g. version 0.99 involves creating the release branch 0.99.X directly on the main repo, where X really is the letter X, not a placeholder. This is considered the feature freeze. The development for the major and minor releases of 0.99 should also happen under 0.99.X. Each release (rc, major, or minor) is a tag under that branch.

In terms of including changes, the first RC ideally counts as a feature freeze. Each coming release candidate and the final release afterwards will include minor documentation changes and bug fixes. Any major enhancement or feature should be excluded.

The minor releases should include bug fixes and some relevant documentation changes only. Any PR resulting in a behavior change which is not a bug fix should be excluded.

First, create a branch, **on your own fork** (to release e.g. 0.999.3):
Then, create a PR to the `scikit-learn/0.999.X` branch (not to master!) with all the desired changes:

```bash
$ git rebase -i upstream/0.999.2
```

Do not forget to add a commit updating sklearn.__version__.

It’s nice to have a copy of the `git rebase -i log` in the PR to help others understand what’s included.

### Making a release

0. Create the release branch on the main repo, if it does not exist. This is done only once, as the major and minor releases happen on the same branch:

```bash
$ git checkout -b 0.99.X
```

Again, X is literal here, and 99 is replaced by the release number. The branches are called 0.19.X, 0.20.X, etc.

1. Update docs. Note that this is for the final release, not necessarily for the RC releases. These changes should be made in master and cherry-picked into the release branch, only before the final release.
   - Edit the `doc/whats_new.rst` file to add release title and commit statistics. You can retrieve commit statistics with:
     ```bash
     $ git shortlog -s 0.99.33.. | cut -f2- | sort --ignore-case | tr \n \';' | sed 's/;/, /g;s/\$/;/'
     ```
   - Update the release date in `whats_new.rst`
   - Edit the `doc/templates/index.html` to change the ‘News’ entry of the front page.

2. On the branch for releasing, update the version number in `sklearn/__init__.py`, the `__version__` variable by removing `dev*` only when ready to release. On master, increment the version in the same place (when branching for release). This means while we’re in the release candidate period, the latest stable is two versions behind the master branch, instead of one.

3. At this point all relevant PRs should have been merged into the `0.99.X` branch. Create the source tarball:
   - Wipe clean your repo:
     ```bash
     $ git clean -xfd
     ```
   - Generate the tarball:
     ```bash
     $ python setup.py sdist
     ```
   - You can also test a binary dist build using:
     ```bash
     $ python setup.py bdist_wheel
     ```
   - You can test if PyPi is going to accept the package using:
     ```bash
     $ twine check dist/*
     ```

8.8. Maintainer / core-developer information
You can run `twine check` after step 5 (fetching artifacts) as well.

The result should be in the `dist/` folder. We will upload it later with the wheels. Check that you can install it in a new virtualenv and that the tests pass.

4. Proceed with caution. Ideally, tags should be created when you’re almost certain that the release is ready, since adding a tag to the main repo can trigger certain automated processes. You can test upload the `sdist` to `test.pypi.org`, and test the next step by setting `BUILD_COMMIT` to the branch name (0.99.X for instance) in a PR to the wheel building repo. Once all works, you can proceed with tagging. Create the tag and push it (if it's an RC, it can be 0.xxxrc1 for instance):

```
$ git tag -a 0.99 # in the 0.99.X branch
$ git push git@github.com:scikit-learn/scikit-learn.git 0.99
```

5. Update the dependency versions and set `BUILD_COMMIT` variable to the release tag at:

https://github.com/MacPython/scikit-learn-wheels

Once the CI has completed successfully, collect the generated binary wheel packages and upload them to PyPI by running the following commands in the scikit-learn source folder (checked out at the release tag):

```
$ rm -r dist # only if there's anything other than the sdist tar.gz there
$ pip install -U wheelhouse_uploader twine
$ python setup.py fetch_artifacts
```

6. Check the content of the `dist/` folder: it should contain all the wheels along with the source tarball (“scikit-learn-RRR.tar.gz”).

Make sure that you do not have developer versions or older versions of the scikit-learn package in that folder.

Before uploading to pypi, you can test upload to test.pypi.org:

```
$ twine upload --verbose --repository-url https://test.pypi.org/legacy/ dist/*
```

Upload everything at once to https://pypi.org:

```
$ twine upload dist/*
```

7. For major/minor (not bug-fix release), update the symlink for `stable` and the `latestStable` variable in https://github.com/scikit-learn/scikit-learn.github.io:

```
$ cd /tmp
$ git clone --depth 1 --no-checkout git@github.com:scikit-learn/scikit-learn.
˓→github.io.git
$ cd scikit-learn.github.io
$ echo stable > .git/info/sparse-checkout
$ git checkout master
$ rm stable
$ ln -s 0.999 stable
$ sed -i "s/latestStable = '.*/latestStable = '0.999';/" versionwarning.js
$ git add stable/ versionwarning.js
$ git commit -m "Update stable to point to 0.999"
$ git push origin master
```

The following GitHub checklist might be helpful in a release PR:

* [ ] update news and what's new date in master and release branch
* [ ] create tag

(continues on next page)
8.8.2 Merging Pull Requests

Individual commits are squashed when a Pull Request (PR) is merged on Github. Before merging,

- the resulting commit title can be edited if necessary. Note that this will rename the PR title by default.
- the detailed description, containing the titles of all the commits, can be edited or deleted.
- for PRs with multiple code contributors care must be taken to keep the Co-authored-by: name <name@example.com> tags in the detailed description. This will mark the PR as having multiple co-authors. Whether code contributions are significantly enough to merit co-authorship is left to the maintainer’s discretion, same as for the “what’s new” entry.

8.8.3 The scikit-learn.org web site

The scikit-learn web site (http://scikit-learn.org) is hosted at GitHub, but should rarely be updated manually by pushing to the https://github.com/scikit-learn/scikit-learn.github.io repository. Most updates can be made by pushing to master (for /dev) or a release branch like 0.99.X, from which Circle CI builds and uploads the documentation automatically.

8.8.4 Travis Cron jobs

From https://docs.travis-ci.com/user/cron-jobs: Travis CI cron jobs work similarly to the cron utility, they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository. Cron jobs always fetch the most recent commit on a particular branch and build the project at that state. Cron jobs can run daily, weekly or monthly, which in practice means up to an hour after the selected time span, and you cannot set them to run at a specific time.

For scikit-learn, Cron jobs are used for builds that we do not want to run in each PR. As an example the build with the dev versions of numpy and scipy is run as a Cron job. Most of the time when this numpy-dev build fail, it is related to a numpy change and not a scikit-learn one, so it would not make sense to blame the PR author for the Travis failure.

The definition of what gets run in the Cron job is done in the .travis.yml config file, exactly the same way as the other Travis jobs. We use a if: type = cron filter in order for the build to be run only in Cron jobs.

The branch targeted by the Cron job and the frequency of the Cron job is set via the web UI at https://www.travis-ci.org/scikit-learn/scikit-learn/settings.
8.8.5 Experimental features

The `sklearn.experimental` module was introduced in 0.21 and contains experimental features / estimators that are subject to change without deprecation cycle.

To create an experimental module, you can just copy and modify the content of `enable_hist_gradient_boosting.py`, or `enable_iterative_imputer.py`.

Note that the public import path must be to a public subpackage (like `sklearn/ensemble` or `sklearn/impute`), not just a `.py` module. Also, the (private) experimental features that are imported must be in a submodule/subpackage of the public subpackage, e.g. `sklearn/ensemble/_hist_gradient_boosting` or `sklearn/impute/_iterative.py`. This is needed so that pickles still work in the future when the features aren’t experimental anymore.

To avoid type checker (e.g. mypy) errors a direct import of experimental estimators should be done in the parent module, protected by the `if typing.TYPE_CHECKING` check. See `sklearn/ensemble/__init__.py`, or `sklearn/impute/__init__.py` for an example.

Please also write basic tests following those in `test_enable_hist_gradient_boosting.py`.

Make sure every user-facing code you write explicitly mentions that the feature is experimental, and add a `# noqa` comment to avoid pep8-related warnings:

```python
# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
```

For the docs to render properly, please also import `enable_my_experimental_feature` in `doc/conf.py`, else sphinx won’t be able to import the corresponding modules. Note that using `from sklearn.experimental import *` does not work.

Note that some experimental classes / functions are not included in the `sklearn.experimental` module: `sklearn.datasets.fetch_openml`.

8.9 Developing with the Plotting API

Scikit-learn defines a simple API for creating visualizations for machine learning. The key features of this API is to run calculations once and to have the flexibility to adjust the visualizations after the fact. This section is intended for developers who wish to develop or maintain plotting tools. For usage, users should refer to the :ref `User Guide <visualizations>`.

8.9.1 Plotting API Overview

This logic is encapsulated into a display object where the computed data is stored and the plotting is done in a `plot` method. The display object’s `__init__` method contains only the data needed to create the visualization. The `plot` method takes in parameters that only have to do with visualization, such as a matplotlib axes. The `plot` method will store the matplotlib artists as attributes allowing for style adjustments through the display object. A `plot_*` helper function accepts parameters to do the computation and the parameters used for plotting. After the helper function creates the display object with the computed values, it calls the display’s `plot` method. Note that the `plot` method defines attributes related to matplotlib, such as the line artist. This allows for customizations after calling the `plot` method.

For example, the `RocCurveDisplay` defines the following methods and attributes:
8.9.2 Plotting with Multiple Axes

Some of the plotting tools like `plot_partial_dependence` and `PartialDependenceDisplay` support plotting on multiple axes. Two different scenarios are supported:

1. If a list of axes is passed in, `plot` will check if the number of axes is consistent with the number of axes it expects and then draws on those axes.
2. If a single axes is passed in, that axes defines a space for multiple axes to be placed. In this case, we suggest using matplotlib’s `~matplotlib.gridspec.GridSpecFromSubplotSpec` to split up the space:

```python
import matplotlib.pyplot as plt
from matplotlib.gridspec import GridSpecFromSubplotSpec

fig, ax = plt.subplots()
gs = GridSpecFromSubplotSpec(2, 2, subplot_spec=ax.get_subplotspec())

ax_top_left = fig.add_subplot(gs[0, 0])
ax_top_right = fig.add_subplot(gs[0, 1])
ax_bottom = fig.add_subplot(gs[1, :])
```

By default, the `ax` keyword in `plot` is `None`. In this case, the single axes is created and the gridspec api is used to create the regions to plot in.

See for example, `plot_partial_dependence` which plots multiple lines and contours using this API. The axes defining the bounding box is saved in a `bounding_ax_` attribute. The individual axes created are stored in an `axes_` ndarray, corresponding to the axes position on the grid. Positions that are not used are set to `None`. Furthermore, the matplotlib Artists are stored in `lines_` and `contours_` where the key is the position on the grid. When a list of axes is passed in, the `axes_.lines_` and `contours_` is a 1d ndarray corresponding to the list of axes passed in.
