6.15.2 Gaussian process classification (GPC) on iris dataset

This example illustrates the predicted probability of GPC for an isotropic and anisotropic RBF kernel on a two-dimensional version for the iris-dataset. The anisotropic RBF kernel obtains slightly higher log-marginal-likelihood by assigning different length-scales to the two feature dimensions.

```

6.15.3 Comparison of kernel ridge and Gaussian process regression

Both kernel ridge regression (KRR) and Gaussian process regression (GPR) learn a target function by employing internally the “kernel trick”. KRR learns a linear function in the space induced by the respective kernel which corresponds to a non-linear function in the original space. The linear function in the kernel space is chosen based on the mean-squared error loss with ridge regularization. GPR uses the kernel to define the covariance of a prior distribution over the target functions and uses the observed training data to define a likelihood function. Based on Bayes theorem, a (Gaussian) posterior distribution over target functions is defined, whose mean is used for prediction.

A major difference is that GPR can choose the kernel’s hyperparameters based on gradient-ascent on the marginal likelihood function while KRR needs to perform a grid search on a cross-validated loss function (mean-squared error loss). A further difference is that GPR learns a generative, probabilistic model of the target function and can thus provide meaningful confidence intervals and posterior samples along with the predictions while KRR only provides predictions.

This example illustrates both methods on an artificial dataset, which consists of a sinusoidal target function and strong noise. The figure compares the learned model of KRR and GPR based on a ExpSineSquared kernel, which is suited for learning periodic functions. The kernel’s hyperparameters control the smoothness (l) and periodicity of the kernel (p). Moreover, the noise level of the data is learned explicitly by GPR by an additional WhiteKernel component in the kernel and by the regularization parameter alpha of KRR.

The figure shows that both methods learn reasonable models of the target function. GPR correctly identifies the periodicity of the function to be roughly 2*pi (6.28), while KRR chooses the doubled periodicity 4*pi. Besides that, GPR provides reasonable confidence bounds on the prediction which are not available for KRR. A major difference between the two methods is the time required for fitting and predicting: while fitting KRR is fast in principle, the grid-search for hyperparameter optimization scales exponentially with the number of hyperparameters (“curse of dimensionality”). The gradient-based optimization of the parameters in GPR does not suffer from this exponential scaling and is thus considerably faster on this example with 3-dimensional hyperparameter space. The time for predicting is similar; however, generating the variance of the predictive distribution of GPR takes considerable longer than just predicting the mean.

```
Time for KRR fitting: 3.234
Time for GPR fitting: 0.056
```
Time for KRR prediction: 0.032
Time for GPR prediction: 0.012
Time for GPR prediction with standard-deviation: 0.017

6.15.6 Probabilistic predictions with Gaussian process classification (GPC)

This example illustrates the predicted probability of GPC for an RBF kernel with different choices of the hyperparameters. The first figure shows the predicted probability of GPC with arbitrarily chosen hyperparameters and with the hyperparameters corresponding to the maximum log-marginal-likelihood (LML).
While the hyperparameters chosen by optimizing LML have a considerably larger LML, they perform slightly worse according to the log-loss on test data. The figure shows that this is because they exhibit a steep change of the class probabilities at the class boundaries (which is good) but have predicted probabilities close to 0.5 far away from the class boundaries (which is bad) This undesirable effect is caused by the Laplace approximation used internally by GPC.

The second figure shows the log-marginal-likelihood for different choices of the kernel’s hyperparameters, highlighting the two choices of the hyperparameters used in the first figure by black dots.
Log Marginal Likelihood (initial): -17.598
Log Marginal Likelihood (optimized): -3.875
Accuracy: 1.000 (initial) 1.000 (optimized)
Log-loss: 0.214 (initial) 0.319 (optimized)

6.15.7 Gaussian process regression (GPR) with noise-level estimation

This example illustrates that GPR with a sum-kernel including a WhiteKernel can estimate the noise level of data. An illustration of the log-marginal-likelihood (LML) landscape shows that there exist two local maxima of LML. The first corresponds to a model with a high noise level and a large length scale, which explains all variations in the data by noise. The second one has a smaller noise level and shorter length scale, which explains most of the variation by the noise-free functional relationship. The second model has a higher likelihood; however, depending on the initial value for the hyperparameters, the gradient-based optimization might also converge to the high-noise solution. It is thus important to repeat the optimization several times for different initializations.
Initial: 1**2 * RBF(length_scale=100) + WhiteKernel(noise_level=1)
Maximum: 0.00316**2 * RBF(length_scale=109) + WhiteKernel(noise_level=0.6)
Log-Marginal-Likelihood: -23.87233736198489
Initial: $1^{**2} \cdot \text{RBF}(\text{length\_scale}=1) + \text{WhiteKernel}(\text{noise\_level}=1e-05)$

Optimum: $0.64^{**2} \cdot \text{RBF}(\text{length\_scale}=0.365) + \text{WhiteKernel}(\text{noise\_level}=0.29)$

Log-Marginal-Likelihood: $-21.805090890162035$

6.15.8 Gaussian Processes regression: basic introductory example

A simple one-dimensional regression example computed in two different ways:

1. A noise-free case
2. A noisy case with known noise-level per datapoint

In both cases, the kernel’s parameters are estimated using the maximum likelihood principle.

The figures illustrate the interpolating property of the Gaussian Process model as well as its probabilistic nature in the form of a pointwise 95% confidence interval.

Note that the parameter alpha is applied as a Tikhonov regularization of the assumed covariance between the training points.
import numpy as np
from matplotlib import pyplot as plt
from sklearn.gaussian_process import GaussianProcessRegressor
from sklearn.gaussian_process.kernels import RBF, ConstantKernel as C

np.random.seed(1)

def f(x):
    """The function to predict.""
    return x * np.sin(x)

# First the noiseless case
X = np.atleast_2d([1., 3., 5., 6., 7., 8.]).T

# Observations
y = f(X).ravel()
# Mesh the input space for evaluations of the real function, the prediction and
# its MSE
x = np.atleast_2d(np.linspace(0, 10, 1000)).T

# Instantiate a Gaussian Process model
kernel = C(1.0, (1e-3, 1e3)) * RBF(10, (1e-2, 1e2))
gp = GaussianProcessRegressor(kernel=kernel, n_restarts_optimizer=9)

# Fit to data using Maximum Likelihood Estimation of the parameters
gp.fit(X, y)

# Make the prediction on the meshed x-axis (ask for MSE as well)
y_pred, sigma = gp.predict(x, return_std=True)

# Plot the function, the prediction and the 95% confidence interval based on
# the MSE
plt.figure()
plt.plot(x, f(x), 'r:', label=r'$f(x) = x\sin(x)$')
plt.plot(X, y, 'r.', markersize=10, label='Observations')
plt.plot(x, y_pred, 'b-', label='Prediction')
plt.fill(np.concatenate([x, x[::-1]]),
         np.concatenate([y_pred - 1.9600 * sigma,
                         (y_pred + 1.9600 * sigma)[::-1]]),
         alpha=.5, fc='b', ec='None', label='95% confidence interval')
plt.xlabel('$x$')
plt.ylabel('$f(x)$')
plt.ylim(-10, 20)
plt.legend(loc='upper left')

# now the noisy case
X = np.linspace(0.1, 9.9, 20)

                               n_restarts_optimizer=10)

# Fit to data using Maximum Likelihood Estimation of the parameters
gp.fit(X, y)

# Make the prediction on the meshed x-axis (ask for MSE as well)
y_pred, sigma = gp.predict(x, return_std=True)

# Plot the function, the prediction and the 95% confidence interval based on
# the MSE
plt.figure()
plt.plot(x, f(x), 'r:', label=r'$f(x) = x\sin(x)$')
plt.errorbar(X.ravel(), y, dy, fmt='r.', markersize=10, label='Observations')
plt.plot(x, y_pred, 'b-', label='Prediction')
plt.fill(np.concatenate([x, x[::-1]]),
         np.concatenate([y_pred - 1.9600 * sigma,
                         (y_pred + 1.9600 * sigma)[::-1]]),
         alpha=.5, fc='b', ec='None', label='95% confidence interval')

plt.xlabel('$x$')
plt.ylabel('$f(x)$')
plt.ylim(-10, 20)
plt.legend(loc='upper left')
np.concatenate([y_pred - 1.9600 * sigma,
                 (y_pred + 1.9600 * sigma)[::-1]],
                 alpha=.5, fc='b', ec='None', label='95% confidence interval')
plt.xlabel('$x$')
plt.ylabel('$f(x)$')
plt.xlim(-10, 20)
plt.legend(loc='upper left')
plt.show()
decay time indicates that we have a locally very close to periodic seasonal component. The correlated noise has an
amplitude of 0.197 ppm with a length scale of 0.138 years and a white-noise contribution of 0.197 ppm. Thus, the
overall noise level is very small, indicating that the data can be very well explained by the model. The figure shows
also that the model makes very confident predictions until around 2015.

6.15.10 Gaussian processes on discrete data structures

This example illustrates the use of Gaussian processes for regression and classification tasks on data that are not in fixed-length feature vector form. This is achieved through the use of kernel functions that operate directly on discrete structures such as variable-length sequences, trees, and graphs.

Specifically, here the input variables are some gene sequences stored as variable-length strings consisting of letters ‘A’, ‘T’, ‘C’, and ‘G’, while the output variables are floating point numbers and True/False labels in the regression and classification tasks, respectively.

Note: Click [here](#) to download the full example code or to run this example in your browser via Binder
A kernel between the gene sequences is defined using R-convolution\(^1\) by integrating a binary letter-wise kernel over all pairs of letters among a pair of strings.

This example will generate three figures.

In the first figure, we visualize the value of the kernel, i.e. the similarity of the sequences, using a colormap. Brighter color here indicates higher similarity.

In the second figure, we show some regression result on a dataset of 6 sequences. Here we use the 1st, 2nd, 4th, and 5th sequences as the training set to make predictions on the 3rd and 6th sequences.

In the third figure, we demonstrate a classification model by training on 6 sequences and make predictions on another 5 sequences. The ground truth here is simply whether there is at least one ‘A’ in the sequence. Here the model makes four correct classifications and fails on one.

Regression on sequences

from sklearn import datasets

X, y = datasets.load_diabetes(return_X_y=True)
print("Computing regularization path using the LARS ...")
```

(continues on next page)
6.16.2 Plot Ridge coefficients as a function of the regularization

Shows the effect of collinearity in the coefficients of an estimator.

Ridge Regression is the estimator used in this example. Each color represents a different feature of the coefficient vector, and this is displayed as a function of the regularization parameter.

This example also shows the usefulness of applying Ridge regression to highly ill-conditioned matrices. For such matrices, a slight change in the target variable can cause huge variances in the calculated weights. In such cases, it is useful to set a certain regularization (alpha) to reduce this variation (noise).

When alpha is very large, the regularization effect dominates the squared loss function and the coefficients tend to zero. At the end of the path, as alpha tends toward zero and the solution tends towards the ordinary least squares, coefficients exhibit big oscillations. In practice it is necessary to tune alpha in such a way that a balance is maintained between both.
# Ridge coefficients as a function of the regularization

6.16.5 Ordinary Least Squares and Ridge Regression Variance

Due to the few points in each dimension and the straight line that linear regression uses to follow these points as well as it can, noise on the observations will cause great variance as shown in the first plot. Every line’s slope can vary quite a bit for each prediction due to the noise induced in the observations.

Ridge regression is basically minimizing a penalised version of the least-squared function. The penalising shrinks the value of the regression coefficients. Despite the few data points in each dimension, the slope of the prediction is much more stable and the variance in the line itself is greatly reduced, in comparison to that of the standard linear regression

6.16.6 Plot Ridge coefficients as a function of the L2 regularization

Ridge Regression is the estimator used in this example. Each color in the left plot represents one different dimension of the coefficient vector, and this is displayed as a function of the regularization parameter. The right plot shows how exact the solution is. This example illustrates how a well defined solution is found by Ridge regression and how regularization affects the coefficients and their values. The plot on the right shows how the difference of the coefficients from the estimator changes as a function of regularization.

In this example the dependent variable Y is set as a function of the input features: y = X*w + c. The coefficient vector w is randomly sampled from a normal distribution, whereas the bias term c is set to a constant.

As alpha tends toward zero the coefficients found by Ridge regression stabilize towards the randomly sampled vector w. For big alpha (strong regularization) the coefficients are smaller (eventually converging at 0) leading to a simpler and biased solution. These dependencies can be observed on the left plot.

The right plot shows the mean squared error between the coefficients found by the model and the chosen vector w. Less regularised models retrieve the exact coefficients (error is equal to 0), stronger regularised models increase the error.

Please note that in this example the data is non-noisy, hence it is possible to extract the exact coefficients.

6.16.8 Polynomial interpolation

This example demonstrates how to approximate a function with a polynomial of degree n_degree by using ridge regression. Concretely, from n_samples 1d points, it suffices to build the Vandermonde matrix, which is n_samples x n_degree+1 and has the following form:

\[
\begin{bmatrix}
1, x_1, x_1 ** 2, x_1 ** 3, \ldots, \\
1, x_2, x_2 ** 2, x_2 ** 3, \ldots
\end{bmatrix}, \ldots
\]

Intuitively, this matrix can be interpreted as a matrix of pseudo features (the points raised to some power). The matrix is akin to (but different from) the matrix induced by a polynomial kernel.

This example shows that you can do non-linear regression with a linear model, using a pipeline to add non-linear features. Kernel methods extend this idea and can induce very high (even infinite) dimensional feature spaces.
```python
import numpy as np
import matplotlib.pyplot as plt
from sklearn.linear_model import Ridge
from sklearn.preprocessing import PolynomialFeatures
from sklearn.pipeline import make_pipeline

def f(x):
    """function to approximate by polynomial interpolation"""
    return x * np.sin(x)

# generate points used to plot
x_plot = np.linspace(0, 10, 100)

# generate points and keep a subset of them
x = np.linspace(0, 10, 100)
rng = np.random.RandomState(0)
```
rng.shuffle(x)
x = np.sort(x[:20])
y = f(x)

# create matrix versions of these arrays
X = x[:, np.newaxis]
X_plot = x_plot[:, np.newaxis]

colors = ['teal', 'yellowgreen', 'gold']
lw = 2
plt.plot(x_plot, f(x_plot), color='cornflowerblue', linewidth=lw, label="ground truth")
plt.scatter(x, y, color='navy', s=30, marker='o', label="training points")

for count, degree in enumerate([3, 4, 5]):
    model = make_pipeline(PolynomialFeatures(degree), Ridge())
    model.fit(X, y)
    y_plot = model.predict(X_plot)
    plt.plot(x_plot, y_plot, color=colors[count], linewidth=lw, label="degree %d" % degree)

plt.legend(loc='lower left')
plt.show()

6.16.9 Logistic function

Shown in the plot is how the logistic regression would, in this synthetic dataset, classify values as either 0 or 1, i.e. class one or two, using the logistic curve.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import linear_model
from scipy.special import expit

# General a toy dataset: it's just a straight line with some Gaussian noise:
xmin, xmax = -5, 5
n_samples = 100
np.random.seed(0)
X = np.random.normal(size=n_samples)
y = (X > 0).astype(np.float)
X[X > 0] *= 4
X += .3 * np.random.normal(size=n_samples)
X = X[:, np.newaxis]

# Fit the classifier
clf = linear_model.LogisticRegression(C=1e5)
clf.fit(X, y)

# and plot the result
plt.figure(1, figsize=(4, 3))
plt.clf()
plt.scatter(X.ravel(), y, color='black', zorder=20)
X_test = np.linspace(-5, 10, 300)
loss = expit(X_test * clf.coef_ + clf.intercept_).ravel()
plt.plot(X_test, loss, color='red', linewidth=3)

# Linear Regression
ols = linear_model.LinearRegression()
ols.fit(X, y)
plt.plot(X_test, ols.coef_ * X_test + ols.intercept_, linewidth=1)
plt.axhline(.5, color='0.5')
plt.ylabel('y')
plt.xlabel('X')
plt.xticks(range(-5, 10))
plt.yticks([0, 0.5, 1])
plt.ylim(-.25, 1.25)
plt.xlim(-4, 10)
plt.legend(('Logistic Regression Model', 'Linear Regression Model'),
            loc="lower right", fontsize='small')
plt.tight_layout()
plt.show()

6.16.10 Regularization path of L1- Logistic Regression

Train L1-penalized logistic regression models on a binary classification problem derived from the Iris dataset.

The models are ordered from strongest regularized to least regularized. The 4 coefficients of the models are collected and plotted as a “regularization path”: on the left-hand side of the figure (strong regularizers), all the coefficients are exactly 0. When regularization gets progressively looser, coefficients can get non-zero values one after the other.

Here we choose the liblinear solver because it can efficiently optimize for the Logistic Regression loss with a non-smooth, sparsity inducing L1 penalty.

Also note that we set a low value for the tolerance to make sure that the model has converged before collecting the coefficients.

We also use warm_start=True which means that the coefficients of the models are reused to initialize the next model fit to speed-up the computation of the full-path.
```python
print(__doc__)

# Author: Alexandre Gramfort <alexandre.gramfort@inria.fr>
# License: BSD 3 clause

from time import time
import numpy as np
import matplotlib.pyplot as plt
from sklearn import linear_model
from sklearn import datasets
from sklearn.svm import l1_min_c

iris = datasets.load_iris()
X = iris.data
```

(continues on next page)
y = iris.target
X = X[y != 2]
y = y[y != 2]
X /= X.max()  # Normalize X to speed-up convergence

# Demo path functions

import numpy as np
import matplotlib.pyplot as plt

def ll_min_c(X, y, loss='log'):
    return float('inf')

cs = ll_min_c(X, y, loss='log') * np.logspace(0, 7, 16)

print("Computing regularization path ...")
start = time()
clf = linear_model.LogisticRegression(penalty='l1', solver='liblinear',
tol=1e-6, max_iter=int(1e6),
warm_start=True,
intercept_scaling=10000.)

coefs_ = []
for c in cs:
    clf.set_params(C=c)
    clf.fit(X, y)
    coefs_.append(clf.coef_.ravel().copy())

coefs_ = np.array(coefs_)
plt.plot(np.log10(cs), coefs_, marker='o')
ymin, ymax = plt.ylim()
plt.xlabel('log(C)')
plt.ylabel('Coefficients')
plt.title('Logistic Regression Path')
plt.axis('tight')
plt.show()

### 6.16.11 Logistic Regression 3-class Classifier

Show below is a logistic-regression classifiers decision boundaries on the first two dimensions (sepal length and width) of the iris dataset. The datapoints are colored according to their labels.
import numpy as np
import matplotlib.pyplot as plt
from sklearn.linear_model import LogisticRegression
from sklearn import datasets

# import some data to play with
iris = datasets.load_iris()
X = iris.data[:, :2]  # we only take the first two features.
Y = iris.target

logreg = LogisticRegression(C=1e5)

# Create an instance of Logistic Regression Classifier and fit the data.
logreg.fit(X, Y)

# Plot the decision boundary. For that, we will assign a color to each
# point in the mesh [x_min, x_max]x[y_min, y_max].
x_min, x_max = X[:, 0].min() - .5, X[:, 0].max() + .5
y_min, y_max = X[:, 1].min() - .5, X[:, 1].max() + .5
h = .02  # step size in the mesh
xx, yy = np.meshgrid(np.arange(x_min, x_max, h), np.arange(y_min, y_max, h))
Z = logreg.predict(np.c_[xx.ravel(), yy.ravel()])

# Put the result into a color plot
Z = Z.reshape(xx.shape)
plt.figure(1, figsize=(4, 3))
plt.pcolormesh(xx, yy, Z, cmap=plt.cm.Paired)

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=Y, edgecolors='k', cmap=plt.cm.Paired)
plt.xlabel('Sepal length')
6.16.12 SGD: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import linear_model

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]
y = [1] * 10 + [-1] * 10
sample_weight = 100 * np.abs(np.random.randn(20))

# and assign a bigger weight to the last 10 samples
sample_weight[:10] *= 10

# plot the weighted data points
xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))
plt.figure()
plt.scatter(X[:, 0], X[:, 1], c=y, s=sample_weight, alpha=0.9, cmap=plt.cm.bone, edgecolor='black')

# fit the unweighted model
clf = linear_model.SGDClassifier(alpha=0.01, max_iter=100)
clf.fit(X, y)
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
no_weights = plt.contour(xx, yy, Z, levels=[0], linestyles=['solid'])

# fit the weighted model
clf = linear_model.SGDClassifier(alpha=0.01, max_iter=100)
clf.fit(X, y, sample_weight=sample_weight)
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
samples_weights = plt.contour(xx, yy, Z, levels=[0], linestyles=['dashed'])

plt.legend([no_weights.collections[0], samples_weights.collections[0]],
            ['no weights', 'with weights'], loc='lower left')
plt.xticks(()
plt.yticks()
plt.show()

### 6.16.13 Linear Regression Example

This example uses the only the first feature of the diabetes dataset, in order to illustrate a two-dimensional plot of this regression technique. The straight line can be seen in the plot, showing how linear regression attempts to draw a straight line that will best minimize the residual sum of squares between the observed responses in the dataset, and the responses predicted by the linear approximation.

The coefficients, the residual sum of squares and the coefficient of determination are also calculated.
Out:

Coefficients:
[938.23786125]
Mean squared error: 2548.07
Coefficient of determination: 0.47

6.16.15 Sparsity Example: Fitting only features 1 and 2

Features 1 and 2 of the diabetes-dataset are fitted and plotted below. It illustrates that although feature 2 has a strong coefficient on the full model, it does not give us much regarding $y$ when compared to just feature 1.
import matplotlib.pyplot as plt
import numpy as np
from mpl_toolkits.mplot3d import Axes3D
from sklearn import datasets, linear_model

X, y = datasets.load_diabetes(return_X_y=True)
indices = (0, 1)
X_train = X[:-20, indices]
X_test = X[-20:, indices]
y_train = y[:-20]
y_test = y[-20:]

ols = linear_model.LinearRegression()
ols.fit(X_train, y_train)

# Plot the figure

def plot_figs(fig_num, elev, azim, X_train, clf):
    fig = plt.figure(fig_num, figsize=(4, 3))
    plt.clf()
    ax = Axes3D(fig, elev=elev, azim=azim)

    ax.scatter(X_train[:, 0], X_train[:, 1], y_train, c='k', marker='+')
    ax.plot_surface(np.array([[-.1, -.1], [.15, .15]]),
                    np.array([[-.1, .15], [-.1, .15]]),
                    clf.predict(np.array([[-.1, -.1, .15, .15],
                                          [-.1, .15, -.1, .15]]).T
                    )

print(__doc__)
Fit Ridge and HuberRegressor on a dataset with outliers. The example shows that the predictions in ridge are strongly influenced by the outliers present in the dataset. The Huber regressor is less influenced by the outliers since the model uses the linear loss for these. As the parameter epsilon is increased for the Huber regressor, the decision function approaches that of the ridge.

6.16.19 Joint feature selection with multi-task Lasso

The multi-task lasso allows to fit multiple regression problems jointly enforcing the selected features to be the same across tasks. This example simulates sequential measurements, each task is a time instant, and the relevant features vary in amplitude over time while being the same. The multi-task lasso imposes that features that are selected at one time point are select for all time point. This makes feature selection by the Lasso more stable.
import matplotlib.pyplot as plt
import numpy as np
from sklearn.linear_model import MultiTaskLasso, Lasso

rng = np.random.RandomState(42)

# Generate some 2D coefficients with sine waves with random frequency and phase
n_samples, n_features, n_tasks = 100, 30, 40
n_relevant_features = 5
coef = np.zeros((n_tasks, n_features))
times = np.linspace(0, 2 * np.pi, n_tasks)
for k in range(n_relevant_features):
    coef[:, k] = np.sin((1. + rng.randn(1)) * times + 3 * rng.randn(1))

X = rng.randn(n_samples, n_features)
Y = np.dot(X, coef.T) + rng.randn(n_samples, n_tasks)

## 6.16.20 MNIST classification using multinomial logistic + L1

Here we fit a multinomial logistic regression with L1 penalty on a subset of the MNIST digits classification task. We use the SAGA algorithm for this purpose: this a solver that is fast when the number of samples is significantly larger than the number of features and is able to finely optimize non-smooth objective functions which is the case with the l1-penalty. Test accuracy reaches > 0.8, while weight vectors remains sparse and therefore more easily interpretable.

Note that this accuracy of this l1-penalized linear model is significantly below what can be reached by an l2-penalized linear model or a non-linear multi-layer perceptron model on this dataset.
Out:

Sparsity with L1 penalty: 79.95%
Test score with L1 penalty: 0.8322
Example run in 29.516 s

```python
import time
import matplotlib.pyplot as plt
import numpy as np

from sklearn.datasets import fetch_openml
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler

### 6.16.24 Curve Fitting with Bayesian Ridge Regression

Computes a Bayesian Ridge Regression of Sinusoids.

See *Bayesian Ridge Regression* for more information on the regressor.

In general, when fitting a curve with a polynomial by Bayesian ridge regression, the selection of initial values of the regularization parameters (alpha, lambda) may be important. This is because the regularization parameters are determined by an iterative procedure that depends on initial values.

In this example, the sinusoid is approximated by a polynomial using different pairs of initial values. When starting from the default values (alpha_init = 1.90, lambda_init = 1.), the bias of the resulting curve is large, and the variance is small. So, lambda_init should be relatively small (1.e-3) so as to reduce the bias. Also, by evaluating log marginal likelihood (L) of these models, we can determine which one is better. It can be concluded that the model with larger L is more likely.
# Generate sinusoidal data with noise
size = 25
rng = np.random.RandomState(1234)
x_train = rng.uniform(0., 1., size)
y_train = func(x_train) + rng.normal(scale=0.1, size=size)
x_test = np.linspace(0., 1., 100)

# Fit by cubic polynomial
n_order = 3
X_train = np.vander(x_train, n_order + 1, increasing=True)
X_test = np.vander(x_test, n_order + 1, increasing=True)

# Plot the true and predicted curves with log marginal likelihood (L)
reg = BayesianRidge(tol=1e-6, fit_intercept=False, compute_score=True)
fig, axes = plt.subplots(1, 2, figsize=(8, 4))

    ax.text(0.05, -1.0, text, fontsize=12)

(continues on next page)
6.16.25 Theil-Sen Regression

Computes a Theil-Sen Regression on a synthetic dataset.

See *Theil-Sen estimator: generalized-median-based estimator* for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the Theil-Sen estimator is robust against outliers. It has a breakdown point of about 29.3% in case of a simple linear regression which means that it can tolerate arbitrary corrupted data (outliers) of up to 29.3% in the two-dimensional case.

The estimation of the model is done by calculating the slopes and intercepts of a subpopulation of all possible combinations of p subsample points. If an intercept is fitted, p must be greater than or equal to n_features + 1. The final slope and intercept is then defined as the spatial median of these slopes and intercepts.

In certain cases Theil-Sen performs better than *RANSAC* which is also a robust method. This is illustrated in the second example below where outliers with respect to the x-axis perturb RANSAC. Tuning the residual_threshold parameter of RANSAC remedies this but in general a priori knowledge about the data and the nature of the outliers is needed. Due to the computational complexity of Theil-Sen it is recommended to use it only for small problems in terms of number of samples and features. For larger problems the max_subpopulation parameter restricts the magnitude of all possible combinations of p subsample points to a randomly chosen subset and therefore also limits the runtime. Therefore, Theil-Sen is applicable to larger problems with the drawback of losing some of its mathematical properties since it then works on a random subset.

plt.show()
Robust fitting is demoed in different situations:

- No measurement errors, only modelling errors (fitting a sine with a polynomial)
- Measurement errors in X
- Measurement errors in y

The median absolute deviation to non corrupt new data is used to judge the quality of the prediction.

What we can see that:

- RANSAC is good for strong outliers in the y direction
- TheilSen is good for small outliers, both in direction X and y, but has a break point above which it performs worse than OLS.
- The scores of HuberRegressor may not be compared directly to both TheilSen and RANSAC because it does not attempt to completely filter the outliers but lessen their effect.

6.16. Generalized Linear Models
6.16.28 L1 Penalty and Sparsity in Logistic Regression

Comparison of the sparsity (percentage of zero coefficients) of solutions when L1, L2 and Elastic-Net penalty are used for different values of C. We can see that large values of C give more freedom to the model. Conversely, smaller values of C constrain the model more. In the L1 penalty case, this leads to sparser solutions. As expected, the Elastic-Net penalty sparsity is between that of L1 and L2.

We classify 8x8 images of digits into two classes: 0-4 against 5-9. The visualization shows coefficients of the models for varying C.

6.16.30 Automatic Relevance Determination Regression (ARD)

Fit regression model with Bayesian Ridge Regression.

See Bayesian Ridge Regression for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the coefficient weights are slightly shifted toward zeros, which stabilises them.

The histogram of the estimated weights is very peaked, as a sparsity-inducing prior is implied on the weights.

The estimation of the model is done by iteratively maximizing the marginal log-likelihood of the observations.

We also plot predictions and uncertainties for ARD for one dimensional regression using polynomial feature expansion. Note the uncertainty starts going up on the right side of the plot. This is because these test samples are outside of the range of the training samples.

6.16.32 Multiclass sparse logistic regression on 20newsgroups

Comparison of multinomial logistic L1 vs one-versus-rest L1 logistic regression to classify documents from the newgroups20 dataset. Multinomial logistic regression yields more accurate results and is faster to train on the larger scale dataset.

Here we use the L1 sparsity that trims the weights of not informative features to zero. This is good if the goal is to extract the strongly discriminative vocabulary of each class. If the goal is to get the best predictive accuracy, it is better to use the non sparsity-inducing L2 penalty instead.

A more traditional (and possibly better) way to predict on a sparse subset of input features would be to use univariate feature selection followed by a traditional (L2-penalised) logistic regression model.

Results obtained with LassoLarsIC are based on AIC/BIC criteria.

Information-criterion based model selection is very fast, but it relies on a proper estimation of degrees of freedom, are derived for large samples (asymptotic results) and assume the model is correct, i.e. that the data are actually generated by this model. They also tend to break when the problem is badly conditioned (more features than samples).

For cross-validation, we use 20-fold with 2 algorithms to compute the Lasso path: coordinate descent, as implemented by the LassoCV class, and Lars (least angle regression) as implemented by the LassoLarsCV class. Both algorithms give roughly the same results. They differ with regards to their execution speed and sources of numerical errors.

Lars computes a path solution only for each kink in the path. As a result, it is very efficient when there are only of few kinks, which is the case if there are few features or samples. Also, it is able to compute the full path without setting any meta parameter. On the opposite, coordinate descent compute the path points on a pre-specified grid (here we use the default). Thus it is more efficient if the number of grid points is smaller than the number of kinks in the path. Such a strategy can be interesting if the number of features is really large and there are enough samples to select a large amount. In terms of numerical errors, for heavily correlated variables, Lars will accumulate more errors, while the coordinate descent algorithm will only sample the path on a grid.

Note how the optimal value of alpha varies for each fold. This illustrates why nested-cross validation is necessary when trying to evaluate the performance of a method for which a parameter is chosen by cross-validation: this choice of parameter may not be optimal for unseen data.
Mean square error on each fold: coordinate descent (train time: 0.31s)

Average across the folds
alpha: CV estimate

6.16.34 Early stopping of Stochastic Gradient Descent

Stochastic Gradient Descent is an optimization technique which minimizes a loss function in a stochastic fashion, performing a gradient descent step sample by sample. In particular, it is a very efficient method to fit linear models.

As a stochastic method, the loss function is not necessarily decreasing at each iteration, and convergence is only guaranteed in expectation. For this reason, monitoring the convergence on the loss function can be difficult.
Another approach is to monitor convergence on a validation score. In this case, the input data is split into a training set and a validation set. The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set. This enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data and reduces the chance of over-fitting the training data.

This early stopping strategy is activated if `early_stopping=True`; otherwise the stopping criterion only uses the training loss on the entire input data. To better control the early stopping strategy, we can specify a parameter `validation_fraction` which set the fraction of the input dataset that we keep aside to compute the validation score. The optimization will continue until the validation score did not improve by at least `tol` during the last `n_iter_no_change` iterations. The actual number of iterations is available at the attribute `n_iter_`.

This example illustrates how the early stopping can used in the `sklearn.linear_model.SGDClassifier` model to achieve almost the same accuracy as compared to a model built without early stopping. This can significantly reduce training time. Note that scores differ between the stopping criteria even from early iterations because some of the training data is held out with the validation stopping criterion.

6.17.1 Permutation Importance with Multicollinear or Correlated Features

In this example, we compute the permutation importance on the Wisconsin breast cancer dataset using `permutation_importance`. The `RandomForestClassifier` can easily get about 97% accuracy on a test dataset. Because this dataset contains multicollinear features, the permutation importance will show that none of the features are important. One approach to handling multicollinearity is by performing hierarchical clustering on the features’ Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster.

Note: See also Permutation Importance vs Random Forest Feature Importance (MDI)

```python
print(__doc__)
from collections import defaultdict
t
import matplotlib.pyplot as plt
import numpy as np
from scipy.stats import spearmanr
from scipy.cluster import hierarchy
from sklearn.datasets import load_breast_cancer
from sklearn.ensemble import RandomForestClassifier
from sklearn.inspection import permutation_importance
from sklearn.model_selection import train_test_split

Random Forest Feature Importance on Breast Cancer Data

First, we train a random forest on the breast cancer dataset and evaluate its accuracy on a test set:

```python
data = load_breast_cancer()
X, y = data.data, data.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)

clf = RandomForestClassifier(n_estimators=100, random_state=42)
clf.fit(X_train, y_train)
print("Accuracy on test data: {:.2f}".format(clf.score(X_test, y_test)))

Out:

Accuracy on test data: 0.97

Next, we plot the tree based feature importance and the permutation importance. The permutation importance plot shows that permuting a feature drops the accuracy by at most 0.012, which would suggest that none of the features are important. This is in contradiction with the high test accuracy computed above: some feature must be important. The permutation importance is calculated on the training set to show how much the model relies on each feature during training.

6.17. Inspection 1265
result = permutation_importance(clf, X_train, y_train, n_repeats=10, random_state=42)
perm_sorted_idx = result.importances_mean.argsort()

tree_importance_sorted_idx = np.argsort(clf.feature_importances_)
tree_indices = np.arange(0, len(clf.feature_importances_)) + 0.5

fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
ax1.barh(tree_indices, clf.feature_importances_[tree_importance_sorted_idx], height=0.7)
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
ax1.set_yticks(tree_indices)
ax1.set_ylim((0, len(clf.feature_importances_)))
ax2.boxplot(result.importances[perm_sorted_idx].T, vert=False, labels=data.feature_names[perm_sorted_idx])
fig.tight_layout()
plt.show()

Handling Multicollinear Features

When features are collinear, permutating one feature will have little effect on the models performance because it can get the same information from a correlated feature. One way to handle multicollinear features is by performing hierarchical clustering on the Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster. First, we plot a heatmap of the correlated features:
Next, we manually pick a threshold by visual inspection of the dendrogram to group our features into clusters and choose a feature from each cluster to keep, select those features from our dataset, and train a new random forest. The test accuracy of the new random forest did not change much compared to the random forest trained on the complete dataset.

```python
cluster_ids = hierarchy.fcluster(corr_linkage, 1, criterion='distance')
cluster_id_to_feature_ids = defaultdict(list)
for idx, cluster_id in enumerate(cluster_ids):
    cluster_id_to_feature_ids[cluster_id].append(idx)
selected_features = [v[0] for v in cluster_id_to_feature_ids.values()]
X_train_sel = X_train[:, selected_features]
X_test_sel = X_test[:, selected_features]
```

(continues on next page)
clf_sel = RandomForestClassifier(n_estimators=100, random_state=42)
clf_sel.fit(X_train_sel, y_train)
print("Accuracy on test data with features removed: {:.2f}\n".format(
    clf_sel.score(X_test_sel, y_test)))

Out:
Accuracy on test data with features removed: 0.97

6.17.2 Permutation Importance vs Random Forest Feature Importance (MDI)

In this example, we will compare the impurity-based feature importance of RandomForestClassifier with the permutation importance on the titanic dataset using permutation_importance. We will show that the impurity-based feature importance can inflate the importance of numerical features.

Furthermore, the impurity-based feature importance of random forests suffers from being computed on statistics derived from the training dataset: the importances can be high even for features that are not predictive of the target variable, as long as the model has the capacity to use them to overfit.

This example shows how to use Permutation Importances as an alternative that can mitigate those limitations.

References:

Data Loading and Feature Engineering

Let’s use pandas to load a copy of the titanic dataset. The following shows how to apply separate preprocessing on numerical and categorical features.
We further include two random variables that are not correlated in any way with the target variable (survived):

- **random_num** is a high cardinality numerical variable (as many unique values as records).
- **random_cat** is a low cardinality categorical variable (3 possible values).

```python
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)
rng = np.random.RandomState(seed=42)
X['random_cat'] = rng.randint(3, size=X.shape[0])
X['random_num'] = rng.randn(X.shape[0])
categorical_columns = ['pclass', 'sex', 'embarked', 'random_cat']
numerical_columns = ['age', 'sibsp', 'parch', 'fare', 'random_num']
X = X[categorical_columns + numerical_columns]
X_train, X_test, y_train, y_test = train_test_split(X, y, stratify=y, random_state=42)
categorical_pipe = Pipeline([
    ('imputer', SimpleImputer(strategy='constant', fill_value='missing')),
    ('onehot', OneHotEncoder(handle_unknown='ignore'))
])
umerical_pipe = Pipeline([
    ('imputer', SimpleImputer(strategy='mean'))
])
preprocessing = ColumnTransformer(
    [('cat', categorical_pipe, categorical_columns),
     ('num', numerical_pipe, numerical_columns)])
rf = Pipeline([
    ('preprocess', preprocessing),
    ('classifier', RandomForestClassifier(random_state=42))
])
rf.fit(X_train, y_train)
```

Out:

```
Pipeline(steps=[('preprocess',
    ColumnTransformer(transformers=[('cat',
        Pipeline(steps=[('imputer',
            SimpleImputer(fill_value='missing')),
        ('onehot',
            OneHotEncoder(handle_unknown='ignore'))))]
        categorical_columns),
    ('num',
        Pipeline(steps=[('imputer',
            SimpleImputer())])
        numerical_columns))]
    ('classifier', RandomForestClassifier(random_state=42))])
```
Accuracy of the Model

Prior to inspecting the feature importances, it is important to check that the model predictive performance is high enough. Indeed there would be little interest of inspecting the important features of a non-predictive model.

Here one can observe that the train accuracy is very high (the forest model has enough capacity to completely memorize the training set) but it can still generalize well enough to the test set thanks to the built-in bagging of random forests.

It might be possible to trade some accuracy on the training set for a slightly better accuracy on the test set by limiting the capacity of the trees (for instance by setting `min_samples_leaf=5` or `min_samples_leaf=10`) so as to limit overfitting while not introducing too much underfitting.

However let’s keep our high capacity random forest model for now so as to illustrate some pitfalls with feature importance on variables with many unique values.

```python
print("RF train accuracy: %0.3f" % rf.score(X_train, y_train))
print("RF test accuracy: %0.3f" % rf.score(X_test, y_test))
```

Out:

```
RF train accuracy: 1.000
RF test accuracy: 0.817
```

Tree’s Feature Importance from Mean Decrease in Impurity (MDI)

The impurity-based feature importance ranks the numerical features to be the most important features. As a result, the non-predictive `random_num` variable is ranked the most important!

This problem stems from two limitations of impurity-based feature importances:

- impurity-based importances are biased towards high cardinality features;
- impurity-based importances are computed on training set statistics and therefore do not reflect the ability of feature to be useful to make predictions that generalize to the test set (when the model has enough capacity).

```python
ohe = (rf.named_steps['preprocess']
    .named_transformers_['cat']
    .named_steps['onehot'])
feature_names = ohe.get_feature_names(input_features=categorical_columns)
feature_names = np.r_[feature_names, numerical_columns]
tree_feature_importances = (rf.named_steps['classifier'].feature_importances_)
sorted_idx = tree_feature_importances.argsort()
y_ticks = np.arange(0, len(feature_names))
fig, ax = plt.subplots()
ax.barh(y_ticks, tree_feature_importances[sorted_idx])
ax.set_yticklabels(feature_names[sorted_idx])
aset_yticks(y_ticks)
ax.set_title("Random Forest Feature Importances (MDI)")
fig.tight_layout()
plt.show()
```
As an alternative, the permutation importances of rf are computed on a held out test set. This shows that the low cardinality categorical feature, sex is the most important feature.

Also note that both random features have very low importances (close to 0) as expected.

```python
result = permutation_importance(rf, X_test, y_test, n_repeats=10,
                                random_state=42, n_jobs=2)
sorted_idx = result.importances_mean.argsort()

fig, ax = plt.subplots()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=X_test.columns[sorted_idx])
ax.set_title("Permutation Importances (test set)")
fig.tight_layout()
plt.show()
```
It is also possible to compute the permutation importances on the training set. This reveals that random_num gets a significantly higher importance ranking than when computed on the test set. The difference between those two plots is a confirmation that the RF model has enough capacity to use that random numerical feature to overfit. You can further confirm this by re-running this example with constrained RF with min_samples_leaf=10.

```python
result = permutation_importance(rf, X_train, y_train, n_repeats=10,
                                random_state=42, n_jobs=2)
sorted_idx = result.importances_mean.argsort()

fig, ax = plt.subplots()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=X_train.columns[sorted_idx])
ax.set_title("Permutation Importances (train set)")
fig.tight_layout()
plt.show()
```
6.17.3 Partial Dependence Plots

Partial dependence plots show the dependence between the target function and a set of ‘target’ features, marginalizing over the values of all other features (the complement features). Due to the limits of human perception, the size of the target feature set must be small (usually, one or two) thus the target features are usually chosen among the most important features.

This example shows how to obtain partial dependence plots from a *MLPRegressor* and a *HistGradientBoostingRegressor* trained on the California housing dataset. The example is taken from [1].

The plots show four 1-way and two 1-way partial dependence plots (omitted for *MLPRegressor* due to computation time). The target variables for the one-way PDP are: median income (*MedInc*), average occupants per household (*AvgOccup*), median house age (*HouseAge*), and average rooms per household (*AveRooms*).

---

2 For classification you can think of it as the regression score before the link function.

California Housing data preprocessing

Center target to avoid gradient boosting init bias: gradient boosting with the ‘recursion’ method does not account for the initial estimator (here the average target, by default)

```python
cal_housing = fetch_california_housing()
X = pd.DataFrame(cal_housing.data, columns=cal_housing.feature_names)
y = cal_housing.target
y -= y.mean()
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.1, random_state=0)
```

Partial Dependence computation for multi-layer perceptron

Let’s fit a MLPRegressor and compute single-variable partial dependence plots

```python
print("Training MLPRegressor...")
tic = time()
est = make_pipeline(QuantileTransformer(),
    MLPRegressor(hidden_layer_sizes=(50, 50),
                 learning_rate_init=0.01,
                 early_stopping=True))
est.fit(X_train, y_train)
print("done in {:.3f}s".format(time() - tic))
print("Test R2 score: {:.2f}".format(est.score(X_test, y_test)))
```

Out:

```
Training MLPRegressor...
done in 4.435s
Test R2 score: 0.81
```

We configured a pipeline to scale the numerical input features and tuned the neural network size and learning rate to get a reasonable compromise between training time and predictive performance on a test set.
Importantly, this tabular dataset has very different dynamic ranges for its features. Neural networks tend to be very sensitive to features with varying scales and forgetting to preprocess the numeric feature would lead to a very poor model.

It would be possible to get even higher predictive performance with a larger neural network but the training would also be significantly more expensive.

Note that it is important to check that the model is accurate enough on a test set before plotting the partial dependence since there would be little use in explaining the impact of a given feature on the prediction function of a poor model.

Let’s now compute the partial dependence plots for this neural network using the model-agnostic (brute-force) method:

```python
print('Computing partial dependence plots...')
tic = time()
# We don't compute the 2-way PDP (5, 1) here, because it is a lot slower
# with the brute method.
features = ['MedInc', 'AveOccup', 'HouseAge', 'AveRooms']
plot_partial_dependence(est, X_train, features,
n_jobs=3, grid_resolution=20)
print("done in {:.3f} s".format(time() - tic))
fig = plt.gcf()
fig.suptitle('Partial dependence of house value on non-location features

for the California housing dataset, with MLPRegressor')
fig.subplots_adjust(hspace=0.3)
```

![Partial dependence plots](attachment:image.png)

Out:
Computing partial dependence plots...  
done in 2.412s

Partial Dependence computation for Gradient Boosting

Let's now fit a GradientBoostingRegressor and compute the partial dependence plots either or one or two variables at a time.

```python
print("Training GradientBoostingRegressor...")
tic = time()
est = HistGradientBoostingRegressor()
est.fit(X_train, y_train)
print("done in {:.3f}s".format(time() - tic))
print("Test R2 score: {:.2f}".format(est.score(X_test, y_test)))
```

Out:

```
Training GradientBoostingRegressor...
done in 0.391s
Test R2 score: 0.85
```

Here, we used the default hyperparameters for the gradient boosting model without any preprocessing as tree-based models are naturally robust to monotonic transformations of numerical features.

Note that on this tabular dataset, Gradient Boosting Machines are both significantly faster to train and more accurate than neural networks. It is also significantly cheaper to tune their hyperparameters (the default tend to work well while this is not often the case for neural networks).

Finally, as we will see next, computing partial dependence plots tree-based models is also orders of magnitude faster making it cheap to compute partial dependence plots for pairs of interacting features:

```python
print('Computing partial dependence plots...')
tic = time()
features = ['MedInc', 'AveOccup', 'HouseAge', 'AveRooms',
           ('AveOccup', 'HouseAge')]
plot_partial_dependence(est, X_train, features,
n_jobs=3, grid_resolution=20)
print("done in {:.3f}s".format(time() - tic))
fig = plt.gcf()
fig.suptitle('Partial dependence of house value on non-location features
  for the California housing dataset, with Gradient Boosting')
fig.subplots_adjust(wspace=0.4, hspace=0.3)
```
Computing partial dependence plots...
done in 0.178s

**Analysis of the plots**

We can clearly see that the median house price shows a linear relationship with the median income (top left) and that the house price drops when the average occupants per household increases (top middle). The top right plot shows that the house age in a district does not have a strong influence on the (median) house price; so does the average rooms per household. The tick marks on the x-axis represent the deciles of the feature values in the training data.

We also observe that `MLPRegressor` has much smoother predictions than `HistGradientBoostingRegressor`. For the plots to be comparable, it is necessary to subtract the average value of the target $y$: The ‘recursion’ method, used by default for `HistGradientBoostingRegressor`, does not account for the initial predictor (in our case the average target). Setting the target average to 0 avoids this bias.

Partial dependence plots with two target features enable us to visualize interactions among them. The two-way partial dependence plot shows the dependence of median house price on joint values of house age and average occupants per household. We can clearly see an interaction between the two features: for an average occupancy greater than two, the house price is nearly independent of the house age, whereas for values less than two there is a strong dependence on age.
3D interaction plots

Let’s make the same partial dependence plot for the 2 features interaction, this time in 3 dimensions.

```python
fig = plt.figure()

features = ('AveOccup', 'HouseAge')
pdp, axes = partial_dependence(est, X_train, features=features,
                              grid_resolution=20)
XX, YY = np.meshgrid(axes[0], axes[1])
Z = pdp[0].T
ax = Axes3D(fig)
surf = ax.plot_surface(XX, YY, Z, rstride=1, cstride=1,
                       cmap=plt.cm.BuPu, edgecolor='k')
ax.set_xlabel(features[0])
ax.set_ylabel(features[1])
ax.set_zlabel('Partial dependence')
# pretty init view
ax.view_init(elev=22, azim=122)
plt.colorbar(surf)
plt.suptitle('Partial dependence of house value on median
              age and average occupancy, with Gradient Boosting')
plt.subplots_adjust(top=0.9)
plt.show()
```

## 6.18.2 Comparison of Manifold Learning methods

An illustration of dimensionality reduction on the S-curve dataset with various manifold learning methods.

For a discussion and comparison of these algorithms, see the [manifold module page](#)

For a similar example, where the methods are applied to a sphere dataset, see [Manifold Learning methods on a severed sphere](#)

Note that the purpose of the MDS is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seeks an isotropic representation of the data in the low-dimensional space.

6.18.4 t-SNE: The effect of various perplexity values on the shape

An illustration of t-SNE on the two concentric circles and the S-curve datasets for different perplexity values. We observe a tendency towards clearer shapes as the perplexity value increases.

The size, the distance and the shape of clusters may vary upon initialization, perplexity values and does not always convey a meaning.

As shown below, t-SNE for higher perplexities finds meaningful topology of two concentric circles, however the size and the distance of the circles varies slightly from the original. Contrary to the two circles dataset, the shapes visually diverge from S-curve topology on the S-curve dataset even for larger perplexity values.

For further details, “How to Use t-SNE Effectively” https://distill.pub/2016/misread-tsne/ provides a good discussion of the effects of various parameters, as well as interactive plots to explore those effects.

6.18.5 Manifold Learning methods on a severed sphere

An application of the different Manifold learning techniques on a spherical data-set. Here one can see the use of dimensionality reduction in order to gain some intuition regarding the manifold learning methods. Regarding the dataset, the poles are cut from the sphere, as well as a thin slice down its side. This enables the manifold learning techniques to ‘spread it open’ whilst projecting it onto two dimensions.

For a similar example, where the methods are applied to the S-curve dataset, see Comparison of Manifold Learning methods

Note that the purpose of the MDS is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seeks an isotropic representation of the data in the low-dimensional space. Here the manifold problem matches fairly that of representing a flat map of the Earth, as with map projection

6.18.6 Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

An illustration of various embeddings on the digits dataset.

The RandomTreesEmbedding, from the sklearn.ensemble module, is not technically a manifold embedding method, as it learn a high-dimensional representation on which we apply a dimensionality reduction method. However, it is often useful to cast a dataset into a representation in which the classes are linearly-separable.

t-SNE will be initialized with the embedding that is generated by PCA in this example, which is not the default setting. It ensures global stability of the embedding, i.e., the embedding does not depend on random initialization.

Linear Discriminant Analysis, from the sklearn.discriminant_analysis module, and Neighborhood Components Analysis, from the sklearn.neighbors module, are supervised dimensionality reduction method, i.e. they make use of the provided labels, contrary to other methods.

6.19 Missing Value Imputation

Examples concerning the `sklearn.impute` module.

Note: Click [here](#) to download the full example code or to run this example in your browser via Binder

6.19.1 Imputing missing values with variants of IterativeImputer

The `sklearn.impute.IterativeImputer` class is very flexible - it can be used with a variety of estimators to do round-robin regression, treating every variable as an output in turn.

In this example we compare some estimators for the purpose of missing feature imputation with `sklearn.impute.IterativeImputer`:

- `BayesianRidge`: regularized linear regression
- `DecisionTreeRegressor`: non-linear regression
- `ExtraTreesRegressor`: similar to missForest in R
- `KNeighborsRegressor`: comparable to other KNN imputation approaches

Of particular interest is the ability of `sklearn.impute.IterativeImputer` to mimic the behavior of missForest, a popular imputation package for R. In this example, we have chosen to use `sklearn.ensemble.ExtraTreesRegressor` instead of `sklearn.ensemble.RandomForestRegressor` (as in missForest) due to its increased speed.

Note that `sklearn.neighbors.KNeighborsRegressor` is different from KNN imputation, which learns from samples with missing values by using a distance metric that accounts for missing values, rather than imputing them.

The goal is to compare different estimators to see which one is best for the `sklearn.impute.IterativeImputer` when using a `sklearn.linear_model.BayesianRidge` estimator on the California housing dataset with a single value randomly removed from each row.

For this particular pattern of missing values we see that `sklearn.ensemble.ExtraTreesRegressor` and `sklearn.linear_model.BayesianRidge` give the best results.
6.19. Missing Value Imputation

```
import numpy as np
import matplotlib.pyplot as plt
import pandas as pd

# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_iterative_imputer  # noqa
from sklearn.datasets import fetch_california_housing
from sklearn.impute import SimpleImputer
from sklearn.impute import IterativeImputer
from sklearn.linear_model import BayesianRidge
from sklearn.tree import DecisionTreeRegressor
from sklearn.ensemble import ExtraTreesRegressor
from sklearn.neighbors import KNeighborsRegressor

6.19.2 Imputing missing values before building an estimator

Missing values can be replaced by the mean, the median or the most frequent value using the basic `sklearn.impute.SimpleImputer`. The median is a more robust estimator for data with high magnitude variables which could dominate results (otherwise known as a ‘long tail’).

With `KNNImputer`, missing values can be imputed using the weighted or unweighted mean of the desired number of nearest neighbors.

Another option is the `sklearn.impute.IterativeImputer`. This uses round-robin linear regression, treating every variable as an output in turn. The version implemented assumes Gaussian (output) variables. If your features are obviously non-Normal, consider transforming them to look more Normal so as to potentially improve performance.

In addition of using an imputing method, we can also keep an indication of the missing information using `sklearn.impute.MissingIndicator` which might carry some information.

---

```python
print(__doc__)
import numpy as np
import matplotlib.pyplot as plt

# To use the experimental IterativeImputer, we need to explicitly ask for it:
from sklearn.experimental import enable_iterative_imputer  # noqa
from sklearn.datasets import load_diabetes

6.20.2 Confusion matrix

Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set. The diagonal elements represent the number of points for which the predicted label is equal to the true label, while off-diagonal elements are those that are mislabeled by the classifier. The higher the diagonal values of the confusion matrix the better, indicating many correct predictions.

The figures show the confusion matrix with and without normalization by class support size (number of elements in each class). This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified.

Here the results are not as good as they could be as our choice for the regularization parameter C was not the best. In real life applications this parameter is usually chosen using Tuning the hyper-parameters of an estimator.

6.20.3 Plotting Validation Curves

In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter gamma. For very low values of gamma, you can see that both the training score and the validation score are low. This is called underfitting. Medium values of gamma will result in high values for both scores, i.e. the classifier is performing fairly well. If gamma is too high, the classifier will overfit, which means that the training score is good but the validation score is poor.
import matplotlib.pyplot as plt
import numpy as np

from sklearn.datasets import load_digits
from sklearn.svm import SVC
from sklearn.model_selection import validation_curve

X, y = load_digits(return_X_y=True)

param_range = np.logspace(-6, -1, 5)
train_scores, test_scores = validation_curve(SVC(), X, y, param_name="gamma", param_range=param_range, scoring="accuracy", n_jobs=1)

train_scores_mean = np.mean(train_scores, axis=1)
train_scores_std = np.std(train_scores, axis=1)
test_scores_mean = np.mean(test_scores, axis=1)
test_scores_std = np.std(test_scores, axis=1)

plt.title("Validation Curve with SVM")
plt.xlabel(r"$\gamma$")
plt.ylabel("Score")
plt.ylim(0.0, 1.1)
lw = 2

(continues on next page)
6.20.4 Underfitting vs. Overfitting

This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions. The plot shows the function that we want to approximate, which is a part of the cosine function. In addition, the samples from the real function and the approximations of different models are displayed. The models have polynomial features of different degrees. We can see that a linear function (polynomial with degree 1) is not sufficient to fit the training samples. This is called underfitting. A polynomial of degree 4 approximates the true function almost perfectly. However, for higher degrees the model will overfit the training data, i.e. it learns the noise of the training data. We evaluate quantitatively overfitting / underfitting by using cross-validation. We calculate the mean squared error (MSE) on the validation set, the higher, the less likely the model generalizes correctly from the training data.
from sklearn.linear_model import LinearRegression
from sklearn.model_selection import cross_val_score

6.20.5 Parameter estimation using grid search with cross-validation

This examples shows how a classifier is optimized by cross-validation, which is done using the `sklearn.model_selection.GridSearchCV` object on a development set that comprises only half of the available labeled...
The performance of the selected hyper-parameters and trained model is then measured on a dedicated evaluation set that was not used during the model selection step.

More details on tools available for model selection can be found in the sections on *Cross-validation: evaluating estimator performance* and *Tuning the hyper-parameters of an estimator*.

Out:

```python
# Tuning hyper-parameters for precision

Best parameters set found on development set:

{'C': 10, 'gamma': 0.001, 'kernel': 'rbf'}

Grid scores on development set:

0.986 (+/-0.016) for {'C': 1, 'gamma': 0.001, 'kernel': 'rbf'}
0.959 (+/-0.028) for {'C': 1, 'gamma': 0.0001, 'kernel': 'rbf'}
0.988 (+/-0.017) for {'C': 10, 'gamma': 0.001, 'kernel': 'rbf'}
0.982 (+/-0.026) for {'C': 10, 'gamma': 0.0001, 'kernel': 'rbf'}
0.988 (+/-0.017) for {'C': 100, 'gamma': 0.0001, 'kernel': 'rbf'}
0.983 (+/-0.026) for {'C': 100, 'gamma': 0.0001, 'kernel': 'rbf'}
0.988 (+/-0.017) for {'C': 1000, 'gamma': 0.0001, 'kernel': 'rbf'}
0.983 (+/-0.026) for {'C': 1000, 'gamma': 0.0001, 'kernel': 'rbf'}

6.20.6 Comparing randomized search and grid search for hyperparameter estimation

Compare randomized search and grid search for optimizing hyperparameters of a random forest. All parameters that influence the learning are searched simultaneously (except for the number of estimators, which poses a time / quality tradeoff).

The randomized search and the grid search explore exactly the same space of parameters. The result in parameter settings is quite similar, while the run time for randomized search is drastically lower.

The performance may slightly worse for the randomized search, and is likely due to a noise effect and would not carry over to a held-out test set.

Note that in practice, one would not search over this many different parameters simultaneously using grid search, but pick only the ones deemed most important.

Out:

```
RandomizedSearchCV took 20.56 seconds for 20 candidates parameter settings.
Model with rank: 1
Mean validation score: 0.920 (std: 0.028)
Parameters: {'alpha': 0.07316411520495676, 'average': False, 'l1_ratio': 0.
  → 2900760721044407}

Model with rank: 2
Mean validation score: 0.920 (std: 0.029)

6.20.7 Train error vs Test error

Illustration of how the performance of an estimator on unseen data (test data) is not the same as the performance on training data. As the regularization increases the performance on train decreases while the performance on test is optimal within a range of values of the regularization parameter. The example with an Elastic-Net regression model and the performance is measured using the explained variance a.k.a. $R^2$.

6.20.8 Receiver Operating Characteristic (ROC) with cross validation

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality using cross-validation.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

This example shows the ROC response of different datasets, created from K-fold cross-validation. Taking all of these curves, it is possible to calculate the mean area under curve, and see the variance of the curve when the training set is split into different subsets. This roughly shows how the classifier output is affected by changes in the training data, and how different the splits generated by K-fold cross-validation are from one another.

Note:

6.20.9 Nested versus non-nested cross-validation

This example compares non-nested and nested cross-validation strategies on a classifier of the iris data set. Nested cross-validation (CV) is often used to train a model in which hyperparameters also need to be optimized. Nested CV estimates the generalization error of the underlying model and its (hyper)parameter search. Choosing the parameters that maximize non-nested CV biases the model to the dataset, yielding an overly-optimistic score.

Model selection without nested CV uses the same data to tune model parameters and evaluate model performance. Information may thus “leak” into the model and overfit the data. The magnitude of this effect is primarily dependent on the size of the dataset and the stability of the model. See Cawley and Talbot\(^1\) for an analysis of these issues.

To avoid this problem, nested CV effectively uses a series of train/validation/test set splits. In the inner loop (here executed by \texttt{GridSearchCV}), the score is approximately maximized by fitting a model to each training set, and then directly maximized in selecting (hyper)parameters over the validation set. In the outer loop (here in \texttt{cross_val_score}), generalization error is estimated by averaging test set scores over several dataset splits.

The example below uses a support vector classifier with a non-linear kernel to build a model with optimized hyperparameters by grid search. We compare the performance of non-nested and nested CV strategies by taking the difference between their scores.

6.20.10 Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

Multiple metric parameter search can be done by setting the `scoring` parameter to a list of metric scorer names or a dict mapping the scorer names to the scorer callables.

The scores of all the scorers are available in the `cv_results_` dict at keys ending in `'_<scorer_name>'` (`'mean_test_precision','rank_test_precision',etc...)

The `best_estimator_`, `best_index_`, `best_score_` and `best_params_` correspond to the scorer (key) that is set to the `refit` attribute.

```python
# Author: Raghav RV <rvraghav93@gmail.com>
# License: BSD

import numpy as np
from matplotlib import pyplot as plt

from sklearn.datasets import make_hastie_10_2
from sklearn.model_selection import GridSearchCV
from sklearn.metrics import make_scorer
from sklearn.metrics import accuracy_score
from sklearn.tree import DecisionTreeClassifier

print(__doc__)

Running GridSearchCV using multiple evaluation metrics

```python
X, y = make_hastie_10_2(n_samples=8000, random_state=42)

# The scorers can be either be one of the predefined metric strings or a scorer
# callable, like the one returned by make_scorer
scoring = {'AUC': 'roc_auc', 'Accuracy': make_scorer(accuracy_score)}

# Setting refit='AUC', refits an estimator on the whole dataset with the
# parameter setting that has the best cross-validated AUC score.
# That estimator is made available at `gs.best_estimator_` along with
# parameters like 'gs.best_score_', 'gs.best_params_' and
# 'gs.best_index_'

gs = GridSearchCV(DecisionTreeClassifier(random_state=42),
                  param_grid={'min_samples_split': range(2, 403, 10)},
                  scoring=scoring, refit='AUC', return_train_score=True)

gs.fit(X, y)
results = gs.cv_results_
```
Plotting the result

```python
plt.figure(figsize=(13, 13))
plt.title("GridSearchCV evaluating using multiple scorers simultaneously", fontsize=16)
plt.xlabel("min_samples_split")
plt.ylabel("Score")

ax = plt.gca()
ax.set_xlim(0, 402)
ax.set_ylim(0.73, 1)
# Get the regular numpy array from the MaskedArray
X_axis = np.array(results['param_min_samples_split'].data, dtype=float)

for scorer, color in zip(sorted(scoring), ['g', 'k']):
    for sample, style in (('train', '--'), ('test', '-')):
        sample_score_mean = results['mean_%s_%s' % (sample, scorer)]
        sample_score_std = results['std_%s_%s' % (sample, scorer)]
        ax.fill_between(X_axis, sample_score_mean - sample_score_std,
                        sample_score_mean + sample_score_std,
                        alpha=0.1 if sample == 'test' else 0, color=color)
        ax.plot(X_axis, sample_score_mean, style, color=color,
                alpha=1 if sample == 'test' else 0.7,
                label="%s (%s)" % (scorer, sample))

best_index = np.nonzero(results['rank_test_%s' % scorer] == 1)[0][0]
best_score = results['mean_test_%s' % scorer][best_index]

# Plot a dotted vertical line at the best score for that scorer marked by x
ax.plot([X_axis[best_index], ] * 2, [0, best_score], linestyle='-.', color=color, marker='x', markeredgewidth=3, ms=8)

# Annotate the best score for that scorer
ax.annotate("%.2f" % best_score,
            (X_axis[best_index], best_score + 0.005))

plt.legend(loc="best")
plt.grid(False)
plt.show()
```
6.20.11 Sample pipeline for text feature extraction and evaluation

The dataset used in this example is the 20 newsgroups dataset which will be automatically downloaded and then cached and reused for the document classification example.

You can adjust the number of categories by giving their names to the dataset loader or setting them to None to get the 20 of them.
Here is a sample output of a run on a quad-core machine:

```
Loading 20 newsgroups dataset for categories:
['alt.atheism', 'talk.religion.misc']
1427 documents
2 categories

Performing grid search...
pipeline: ['vect', 'tfidf', 'clf']
parameters:
{'clf__alpha': (1.0000000000000001e-05, 9.9999999999999995e-07),
 'clf__max_iter': (10, 50, 80),
 'clf__penalty': ('l2', 'elasticnet'),
 'tfidf__use_idf': (True, False),
 'vect__max_n': (1, 2),
 'vect__max_df': (0.5, 0.75, 1.0),
 'vect__max_features': (None, 5000, 10000, 50000)}
done in 1737.030s

Best score: 0.940
Best parameters set:
clf__alpha: 9.9999999999999995e-07
clf__max_iter: 50
clf__penalty: 'elasticnet'
tfidf__use_idf: True
vect__max_n: 2
vect__max_df: 0.75
vect__max_features: 50000
```

6.20.13 Visualizing cross-validation behavior in scikit-learn

Choosing the right cross-validation object is a crucial part of fitting a model properly. There are many ways to split data into training and test sets in order to avoid model overfitting, to standardize the number of groups in test sets, etc.

This example visualizes the behavior of several common scikit-learn objects for comparison.

```python
from sklearn.model_selection import (TimeSeriesSplit, KFold, ShuffleSplit,
                                        StratifiedKFold, GroupShuffleSplit,
                                        GroupKFold, StratifiedShuffleSplit)
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.patches import Patch
np.random.seed(1338)
cmap_data = plt.cm.Paired
cmap_cv = plt.cm.coolwarm
n_splits = 4

Visualize our data

First, we must understand the structure of our data. It has 100 randomly generated input datapoints, 3 classes split unevenly across datapoints, and 10 “groups” split evenly across datapoints.

As we’ll see, some cross-validation objects do specific things with labeled data, others behave differently with grouped data, and others do not use this information.

To begin, we’ll visualize our data.

```python
# Generate the class/group data
n_points = 100
X = np.random.randn(100, 10)
percentiles_classes = [.1, .3, .6]
y = np.hstack([ii * int(100 * perc)
               for ii, perc in enumerate(percentiles_classes)])
# Evenly spaced groups repeated once
groups = np.hstack([ii * 10 for ii in range(10)])

def visualize_groups(classes, groups, name):
    # Visualize dataset groups
    fig, ax = plt.subplots()
    ax.scatter(range(len(groups)), [.5] * len(groups), c=groups, marker='_',
               lw=50, cmap=cmap_data)
    ax.scatter(range(len(groups)), [3.5] * len(groups), c=classes, marker='_',
               lw=50, cmap=cmap_data)
    ax.set(ylim=[-1, 5], yticks=[.5, 3.5],
           yticklabels=['Data\ngroup', 'Data\nclass'],
           xlabel="Sample index")
visualize_groups(y, groups, 'no groups')
```

6.20. Model Selection 1345
Define a function to visualize cross-validation behavior

We’ll define a function that lets us visualize the behavior of each cross-validation object. We’ll perform 4 splits of the data. On each split, we’ll visualize the indices chosen for the training set (in blue) and the test set (in red).

```python
def plot_cv_indices(cv, X, y, group, ax, n_splits, lw=10):
    """Create a sample plot for indices of a cross-validation object."""
    # Generate the training/testing visualizations for each CV split
    for ii, (tr, tt) in enumerate(cv.split(X=X, y=y, groups=group)):
        # Fill in indices with the training/test groups
        indices = np.array([np.nan] * len(X))
        indices[tt] = 1
        indices[tr] = 0

        # Visualize the results
        ax.scatter(range(len(indices)), [ii + .5] * len(indices),
                   c=indices, marker='_', lw=lw, cmap=cmap_cv,
                   vmin=-.2, vmax=1.2)

    # Plot the data classes and groups at the end
    ax.scatter(range(len(X)), [ii + 1.5] * len(X),
               c=y, marker='o', lw=lw, cmap=cmap_data)
```

(continues on next page)
Let's see how it looks for the `KFold` cross-validation object:

```python
fig, ax = plt.subplots()
cv = KFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```

![KFold Diagram](image)

Out:

```
<matplotlib.axes._subplots.AxesSubplot object at 0x7f6ad5416c50>
```

As you can see, by default the KFold cross-validation iterator does not take either datapoint class or group into consideration. We can change this by using the `StratifiedKFold` like so.
fig, ax = plt.subplots()
cv = StratifiedKFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)

In this case, the cross-validation retained the same ratio of classes across each CV split. Next we’ll visualize this behavior for a number of CV iterators.

**Visualize cross-validation indices for many CV objects**

Let’s visually compare the cross validation behavior for many scikit-learn cross-validation objects. Below we will loop through several common cross-validation objects, visualizing the behavior of each.

Note how some use the group/class information while others do not.

cvs = [KFold, GroupKFold, ShuffleSplit, StratifiedKFold,
       GroupShuffleSplit, StratifiedShuffleSplit, TimeSeriesSplit]

for cv in cvs:
    this_cv = cv(n_splits=n_splits)
```python
fig, ax = plt.subplots(figsize=(6, 3))
plot_cv_indices(this_cv, X, y, groups, ax, n_splits)
ax.legend([Patch(color=cmap_cv(.8)), Patch(color=cmap_cv(.02))],
           ['Testing set', 'Training set'], loc=(1.02, .8))
# Make the legend fit
plt.tight_layout()
fig.subplots_adjust(right=.7)
plt.show()
```

6.20.14 Receiver Operating Characteristic (ROC)

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

ROC curves are typically used in binary classification to study the output of a classifier. In order to extend ROC curve and ROC area to multi-label classification, it is necessary to binarize the output. One ROC curve can be drawn per label, but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Another evaluation measure for multi-label classification is macro-averaging, which gives equal weight to the classification of each label.

Note:

See also sklearn.metrics.roc_auc_score, Receiver Operating Characteristic (ROC) with cross validation

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from itertools import cycle
```

plt.show()
Area under ROC for the multiclass problem

The `sklearn.metrics.roc_auc_score` function can be used for multi-class classification. The multi-class One-vs-One scheme compares every unique pairwise combination of classes. In this section, we calculate the AUC using the OvR and OvO schemes. We report a macro average, and a prevalence-weighted average.

```python
y_prob = classifier.predict_proba(X_test)
macro_roc_auc_ovo = roc_auc_score(y_test, y_prob, multi_class="ovo",
                                 average="macro")
weighted_roc_auc_ovo = roc_auc_score(y_test, y_prob, multi_class="ovo",
                                     average="weighted")
macro_roc_auc_ovr = roc_auc_score(y_test, y_prob, multi_class="ovr",
                                   average="macro")
weighted_roc_auc_ovr = roc_auc_score(y_test, y_prob, multi_class="ovr",

### 6.20.15 Precision-Recall

Example of Precision-Recall metric to evaluate classifier output quality.

Precision-Recall is a useful measure of success of prediction when the classes are very imbalanced. In information retrieval, precision is a measure of result relevancy, while recall is a measure of how many truly relevant results are returned.

The precision-recall curve shows the tradeoff between precision and recall for different threshold. A high area under the curve represents both high recall and high precision, where high precision relates to a low false positive rate, and high recall relates to a low false negative rate. High scores for both show that the classifier is returning accurate results (high precision), as well as returning a majority of all positive results (high recall).

A system with high recall but low precision returns many results, but most of its predicted labels are incorrect when compared to the training labels. A system with high precision but low recall is just the opposite, returning very few results, but most of its predicted labels are correct when compared to the training labels. An ideal system with high precision and high recall will return many results, with all results labeled correctly.
Precision ($P$) is defined as the number of true positives ($T_p$) over the number of true positives plus the number of false positives ($F_p$).

$$P = \frac{T_p}{T_p + F_p}$$

Recall ($R$) is defined as the number of true positives ($T_p$) over the number of true positives plus the number of false negatives ($F_n$).

$$R = \frac{T_p}{T_p + F_n}$$

These quantities are also related to the ($F_1$) score, which is defined as the harmonic mean of precision and recall.

$$F_1 = 2 \frac{P \times R}{P + R}$$

Note that the precision may not decrease with recall. The definition of precision ($\frac{T_p}{T_p + F_p}$) shows that lowering the threshold of a classifier may increase the denominator, by increasing the number of results returned. If the threshold was previously set too high, the new results may all be true positives, which will increase precision. If the previous threshold was about right or too low, further lowering the threshold will introduce false positives, decreasing precision.

Recall is defined as $\frac{T_p}{T_p + F_n}$. where $T_p + F_n$ does not depend on the classifier threshold. This means that lowering the classifier threshold may increase recall, by increasing the number of true positive results. It is also possible that lowering the threshold may leave recall unchanged, while the precision fluctuates.

The relationship between recall and precision can be observed in the stairstep area of the plot - at the edges of these steps a small change in the threshold considerably reduces precision, with only a minor gain in recall.

**Average precision** (AP) summarizes such a plot as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$$AP = \sum_n (R_n - R_{n-1}) P_n$$

where $P_n$ and $R_n$ are the precision and recall at the nth threshold. A pair ($R_k, P_k$) is referred to as an **operating point**.

AP and the trapezoidal area under the operating points (sklearn.metrics.auc) are common ways to summarize a precision-recall curve that lead to different results. Read more in the **User Guide**.

Precision-recall curves are typically used in binary classification to study the output of a classifier. In order to extend the precision-recall curve and average precision to multi-class or multi-label classification, it is necessary to binarize the output. One curve can be drawn per label, but one can also draw a precision-recall curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

**Note:**

See also `sklearn.metrics.average_precision_score`, `sklearn.metrics.recall_score`, `sklearn.metrics.precision_score`, `sklearn.metrics.f1_score`

---

**In binary classification settings**

**Create simple data**

Try to differentiate the two first classes of the iris data

```python
from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
import numpy as np
iris = datasets.load_iris()
```

(continues on next page)
X = iris.data
y = iris.target

# Add noisy features
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# Limit to the two first classes, and split into training and test
X_train, X_test, y_train, y_test = train_test_split(X[y < 2], y[y < 2],
                                                      test_size=.5,
                                                      random_state=random_state)

# Create a simple classifier
classifier = svm.LinearSVC(random_state=random_state)
classifier.fit(X_train, y_train)
y_score = classifier.decision_function(X_test)

Compute the average precision score

```python
from sklearn.metrics import average_precision_score
average_precision = average_precision_score(y_test, y_score)
print('Average precision-recall score: {0:0.2f}'.format(average_precision))
```

Out:

```
Average precision-recall score: 0.88
```

Plot the Precision-Recall curve

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import plot_precision_recall_curve
import matplotlib.pyplot as plt

disp = plot_precision_recall_curve(classifier, X_test, y_test)
disp.ax_.set_title('2-class Precision-Recall curve: ' +
                   'AP={0:.2f}'.format(average_precision))
```
In multi-label settings

Create multi-label data, fit, and predict

We create a multi-label dataset, to illustrate the precision-recall in multi-label settings

```python
from sklearn.preprocessing import label_binarize

# Use label_binarize to be multi-label like settings
Y = label_binarize(y, classes=[0, 1, 2])
n_classes = Y.shape[1]

# Split into training and test
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=.5,
                                                  random_state=random_state)

# We use OneVsRestClassifier for multi-label prediction
from sklearn.multiclass import OneVsRestClassifier

# Run classifier
```

(continues on next page)
classifier = OneVsRestClassifier(svm.LinearSVC(random_state=random_state))
classifier.fit(X_train, Y_train)
y_score = classifier.decision_function(X_test)

The average precision score in multi-label settings

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import average_precision_score

# For each class
precision = dict()
recall = dict()
average_precision = dict()
for i in range(n_classes):
    precision[i], recall[i], _ = precision_recall_curve(Y_test[:, i],
             y_score[:, i])
    average_precision[i] = average_precision_score(Y_test[:, i], y_score[:, i])

# A "micro-average": quantifying score on all classes jointly
precision["micro"], recall["micro"], _ = precision_recall_curve(Y_test.ravel(),
                   y_score.ravel())
average_precision["micro"] = average_precision_score(Y_test, y_score,
                   average="micro")

print("Average precision score, micro-averaged over all classes: (0:0.2f)".
             format(average_precision["micro"]))
```

Out:

```
Average precision score, micro-averaged over all classes: 0.43
```

Plot the micro-averaged Precision-Recall curve

```python
plt.figure()
plt.step(recall["micro"], precision["micro"], where='post')
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title(
    "Average precision score, micro-averaged over all classes: AP=(0:0.2f)".
    format(average_precision["micro"]))
```
Out:

Text(0.5, 1.0, 'Average precision score, micro-averaged over all classes: AP=0.43')

Plot Precision-Recall curve for each class and iso-f1 curves

```
from itertools import cycle
# setup plot details
colors = cycle( ['navy', 'turquoise', 'darkorange', 'cornflowerblue', 'teal'] )

plt.figure(figsize=(7, 8))
f_scores = np.linspace(0.2, 0.8, num=4)
lines = []
labels = []
for f_score in f_scores:
    x = np.linspace(0.01, 1)
y = f_score * x / (2 * x - f_score)
l, = plt.plot(x[y >= 0], y[y >= 0], color='gray', alpha=0.2)
plt.annotate('f1={0:0.1f}'.format(f_score), xy=(0.9, y[45] + 0.02))
lines.append(l)
labels.append('iso-f1 curves')
l, = plt.plot(recall["micro"], precision["micro"], color='gold', lw=2)
lines.append(l)
```

(continues on next page)
labels.append('micro-average Precision-recall (area = {0:0.2f})''
              .format(average_precision['micro']))

for i, color in zip(range(n_classes), colors):
    l, = plt.plot(recall[i], precision[i], color=color, lw=2)
    lines.append(l)
    labels.append('Precision-recall for class {0} (area = {1:0.2f})''
                  .format(i, average_precision[i]))

fig = plt.gcf()
fig.subplots_adjust(bottom=0.25)
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.title('Extension of Precision-Recall curve to multi-class')
plt.legend(lines, labels, loc=(0, -.38), prop=dict(size=14))

plt.show()
Extension of Precision-Recall curve to multi-class

iso-f1 curves
micro-average Precision-recall (area = 0.43)
Precision-recall for class 0 (area = 0.56)
Precision-recall for class 1 (area = 0.37)

6.20.16 Plotting Learning Curves

In the first column, first row the learning curve of a naive Bayes classifier is shown for the digits dataset. Note that the training score and the cross-validation score are both not very good at the end. However, the shape of the curve can be found in more complex datasets very often: the training score is very high at the beginning and decreases and the cross-validation score is very low at the beginning and increases. In the second column, first row we see the learning curve of an SVM with RBF kernel. We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples. The plots in the second row show the times required by the models to train with various sizes of training dataset. The plots in the third row show how much time was required to train the models for each training sizes.
Learning Curves (Naive Bayes)

Learning Curves (SVM, RBF kernel, $\gamma = 0.001$)

Scalability of the model

Performance of the model
from sklearn.naive_bayes import GaussianNB
from sklearn.svm import SVC
from sklearn.datasets import load_digits
from sklearn.model_selection import learning_curve
from sklearn.model_selection import ShuffleSplit

def plot_learning_curve(estimator, title, X, y, axes=None, ylim=None, cv=None, n_jobs=None, train_sizes=np.linspace(.1, 1.0, 5)):
    """
    Generate 3 plots: the test and training learning curve, the training
    samples vs fit times curve, the fit times vs score curve.

    Parameters
    ----------
    estimator : object type that implements the "fit" and "predict" methods
        An object of that type which is cloned for each validation.
    title : string
        Title for the chart.
    X : array-like, shape (n_samples, n_features)
        Training vector, where n_samples is the number of samples and
        n_features is the number of features.
    y : array-like, shape (n_samples) or (n_samples, n_features), optional
        Target relative to X for classification or regression;
        None for unsupervised learning.
    axes : array of 3 axes, optional (default=None)
        Axes to use for plotting the curves.
    ylim : tuple, shape (ymin, ymax), optional
        Defines minimum and maximum yvalues plotted.
    cv : int, cross-validation generator or an iterable, optional
        Determines the cross-validation splitting strategy.
        Possible inputs for cv are:
        - None, to use the default 5-fold cross-validation,
        - integer, to specify the number of folds.
        - :term:`CV splitter`
        - An iterable yielding (train, test) splits as arrays of indices.

        For integer/None inputs, if `y` is binary or multiclass,
        :class:`StratifiedKFold` is used. If the estimator is not a classifier
        or if `y` is neither binary nor multiclass, :class:`KFold` is used.

        Refer :ref:`User Guide <cross_validation>` for the various
        cross-validators that can be used here.
    n_jobs : int or None, optional (default=None)
        Number of jobs to run in parallel.
        `None` means 1 unless in a :obj:`joblib.parallel_backend` context.
        
(continues on next page)
``-1`` means using all processors. See :term:`Glossary <n_jobs>` for more details.

**train_sizes**: array-like, shape (n_ticks,), dtype float or int

Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: np.linspace(0.1, 1.0, 5))

``

6.21 Multioutput methods

Examples concerning the sklearn.multioutput module.

Note:  Click here to download the full example code or to run this example in your browser via Binder

6.21.1 Classifier Chain

Example of using classifier chain on a multilabel dataset.

For this example we will use the yeast dataset which contains 2417 datapoints each with 103 features and 14 possible labels. Each data point has at least one label. As a baseline we first train a logistic regression classifier for each of the 14 labels. To evaluate the performance of these classifiers we predict on a held-out test set and calculate the jaccard score for each sample.
Next we create 10 classifier chains. Each classifier chain contains a logistic regression model for each of the 14 labels. The models in each chain are ordered randomly. In addition to the 103 features in the dataset, each model gets the predictions of the preceding models in the chain as features (note that by default at training time each model gets the true labels as features). These additional features allow each chain to exploit correlations among the classes. The Jaccard similarity score for each chain tends to be greater than that of the set independent logistic models.

Because the models in each chain are arranged randomly there is significant variation in performance among the chains. Presumably there is an optimal ordering of the classes in a chain that will yield the best performance. However we do not know that ordering a priori. Instead we can construct an voting ensemble of classifier chains by averaging the binary predictions of the chains and apply a threshold of 0.5. The Jaccard similarity score of the ensemble is greater than that of the independent models and tends to exceed the score of each chain in the ensemble (although this is not guaranteed with randomly ordered chains).

```python

## 6.22.2 Outlier detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for outlier detection which is the default use case of this estimator in scikit-learn. Note that when LOF is used for outlier detection it has no predict, decision_function and score_samples methods. See User Guide: for details on the difference between outlier detection and novelty detection and how to use LOF for novelty detection.
The number of neighbors considered (parameter \texttt{n
d_neighbors}) is typically set 1) greater than the minimum number of 
samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than 
the maximum number of close by samples that can potentially be local outliers. In practice, such informations are 
generally not available, and taking \texttt{n_neighbors=20} appears to work well in general.

```
import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

# Generate train data
X_inliers = 0.3 * np.random.randn(100, 2)
X_inliers = np.r_[X_inliers + 2, X_inliers - 2]

# Generate some outliers
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))
X = np.r_[X_inliers, X_outliers]

n_outliers = len(X_outliers)
ground_truth = np.ones(len(X), dtype=int)

6.22.6 Caching nearest neighbors

This examples demonstrates how to precompute the k nearest neighbors before using them in KNeighborsClassifier. KNeighborsClassifier can compute the nearest neighbors internally, but precomputing them can have several benefits, such as finer parameter control, caching for multiple use, or custom implementations.

Here we use the caching property of pipelines to cache the nearest neighbors graph between multiple fits of KNeighborsClassifier. The first call is slow since it computes the neighbors graph, while subsequent call are faster as they do not need to recompute the graph. Here the durations are small since the dataset is small, but the gain can be more substantial when the dataset grows larger, or when the grid of parameter to search is large.

```python
from tempfile import TemporaryDirectory
import matplotlib.pyplot as plt
from sklearn.neighbors import KNeighborsTransformer, KNeighborsClassifier
from sklearn.model_selection import GridSearchCV
from sklearn.datasets import load_digits
from sklearn.pipeline import Pipeline

print(__doc__)

X, y = load_digits(return_X_y=True)
n_neighbors_list = [1, 2, 3, 4, 5, 6, 7, 8, 9]

# The transformer computes the nearest neighbors graph using the maximum number
# of neighbors necessary in the grid search. The classifier model filters the
# nearest neighbors graph as required by its own n_neighbors parameter.
graph_model = KNeighborsTransformer(n_neighbors=max(n_neighbors_list),
                                     mode='distance')

classifier_model = KNeighborsClassifier(metric='precomputed')

print(__doc__)

X, y = load_digits(return_X_y=True)
n_neighbors_list = [1, 2, 3, 4, 5, 6, 7, 8, 9]

# The transformer computes the nearest neighbors graph using the maximum number
# of neighbors necessary in the grid search. The classifier model filters the
# nearest neighbors graph as required by its own n_neighbors parameter.
graph_model = KNeighborsTransformer(n_neighbors=max(n_neighbors_list),
                                     mode='distance')

classifier_model = KNeighborsClassifier(metric='precomputed')

with TemporaryDirectory(prefix="sklearn_graph_cache_") as tmpdir:
    full_model = Pipeline(
        steps=[('graph', graph_model), ('classifier', classifier_model)],
        memory=tmpdir)

    param_grid = {'classifier__n_neighbors': n_neighbors_list}
    grid_model = GridSearchCV(full_model, param_grid)
    grid_model.fit(X, y)

    # Plot the results of the grid search.
```

6.22.7 Neighborhood Components Analysis Illustration

This example illustrates a learned distance metric that maximizes the nearest neighbors classification accuracy. It provides a visual representation of this metric compared to the original point space. Please refer to the User Guide for more information.

```python
# License: BSD 3 clause
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_classification
from sklearn.neighbors import NeighborhoodComponentsAnalysis
from matplotlib import cm
from sklearn.utils.fixes import logsumexp

print(__doc__)
```

Original points

First we create a data set of 9 samples from 3 classes, and plot the points in the original space. For this example, we focus on the classification of point no. 3. The thickness of a link between point no. 3 and another point is proportional to their distance.

```python
X, y = make_classification(n_samples=9, n_features=2, n_informative=2,
                           n_redundant=0, n_classes=3, n_clusters_per_class=1,
                           class_sep=1.0, random_state=0)

plt.figure(1)
ax = plt.gca()
for i in range(X.shape[0]):
    ax.text(X[i, 0], X[i, 1], str(i), va='center', ha='center')
    ax.scatter(X[i, 0], X[i, 1], s=300, c=cm.Set1(y[i]), alpha=0.4)

ax.set_title("Original points")
ax.axes.get_xaxis().set_visible(False)
```

```python
fig, axes = plt.subplots(1, 2, figsize=(8, 4))
axes[0].errorbar(x=n_neighbors_list,
                 y=grid_model.cv_results_['mean_test_score'],
                 yerr=grid_model.cv_results_['std_test_score'])
axes[0].set(xlabel='n_neighbors', title='Classification accuracy')
axes[1].errorbar(x=n_neighbors_list, y=grid_model.cv_results_['mean_fit_time'],
                 yerr=grid_model.cv_results_['std_fit_time'], color='r')
axes[1].set(xlabel='n_neighbors', title='Fit time (with caching)')
fig.tight_layout()
plt.show()
```

Total running time of the script: ( 0 minutes 5.013 seconds)
Estimated memory usage: 8 MB

Note: Click here to download the full example code or to run this example in your browser via Binder
ax.axes.get_yaxis().set_visible(False)
ax.axis('equal')  # so that boundaries are displayed correctly as circles

def link_thickness_i(X, i):
    diff_embedded = X[i] - X
    dist_embedded = np.einsum('ij,ij->i', diff_embedded, diff_embedded)
    dist_embedded[i] = np.inf

    # compute exponentiated distances (use the log-sum-exp trick to
    # avoid numerical instabilities
    exp_dist_embedded = np.exp(-dist_embedded -
                              logsumexp(-dist_embedded))
    return exp_dist_embedded

def relate_point(X, i, ax):
    pt_i = X[i]
    for j, pt_j in enumerate(X):
        thickness = link_thickness_i(X, i)
        if i != j:
            line = ([pt_i[0], pt_j[0]], [pt_i[1], pt_j[1]])
            ax.plot(*line, c=cm.Set1(y[j]),
                    linewidth=5*thickness[j])

i = 3
relate_point(X, i, ax)
plt.show()
Learning an embedding

We use `NeighborhoodComponentsAnalysis` to learn an embedding and plot the points after the transformation. We then take the embedding and find the nearest neighbors.

```python
nca = NeighborhoodComponentsAnalysis(max_iter=30, random_state=0)
nca = nca.fit(X, y)
plt.figure(2)
ax2 = plt.gca()
X_embedded = nca.transform(X)
relate_point(X_embedded, i, ax2)

for i in range(len(X)):
    ax2.text(X_embedded[i, 0], X_embedded[i, 1], str(i),
             va='center', ha='center')
    ax2.scatter(X_embedded[i, 0], X_embedded[i, 1], s=300, c=cm.Set1(y[i]),
                alpha=0.4)

ax2.set_title("NCA embedding")
ax2.axes.get_xaxis().set_visible(False)
ax2.axes.get_yaxis().set_visible(False)
ax2.axis('equal')
plt.show()
```
6.22.8 Novelty detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for novelty detection. Note that when LOF is used for novelty detection you MUST not use predict, decision_function and score_samples on the training set as this would lead to wrong results. You must only use these methods on new unseen data (which are not in the training set). See User Guide: for details on the difference between outlier detection and novelty detection and how to use LOF for outlier detection.

The number of neighbors considered, (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.
import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

plt.show()
This example compares different (linear) dimensionality reduction methods applied on the Digits data set. The data set contains images of digits from 0 to 9 with approximately 180 samples of each class. Each image is of dimension 8x8 = 64, and is reduced to a two-dimensional data point.

Principal Component Analysis (PCA) applied to this data identifies the combination of attributes (principal components, or directions in the feature space) that account for the most variance in the data. Here we plot the different samples on the 2 first principal components.

Linear Discriminant Analysis (LDA) tries to identify attributes that account for the most variance between classes. In particular, LDA, in contrast to PCA, is a supervised method, using known class labels.

Neighborhood Components Analysis (NCA) tries to find a feature space such that a stochastic nearest neighbor algorithm will give the best accuracy. Like LDA, it is a supervised method.

One can see that NCA enforces a clustering of the data that is visually meaningful despite the large reduction in dimension.

6.22.11 Kernel Density Estimate of Species Distributions

This shows an example of a neighbors-based query (in particular a kernel density estimate) on geospatial data, using a Ball Tree built upon the Haversine distance metric – i.e. distances over points in latitude/longitude. The dataset is provided by Phillips et. al. (2006). If available, the example uses basemap to plot the coast lines and national boundaries of South America.

This example does not perform any learning over the data (see Species distribution modeling for an example of classification based on the attributes in this dataset). It simply shows the kernel density estimate of observed data points in geospatial coordinates.

The two species are:

- “Bradypus variegatus”, the Brown-throated Sloth.
- “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

6.22.12 Simple 1D Kernel Density Estimation

This example uses the `sklearn.neighbors.KernelDensity` class to demonstrate the principles of Kernel Density Estimation in one dimension.

The first plot shows one of the problems with using histograms to visualize the density of points in 1D. Intuitively, a histogram can be thought of as a scheme in which a unit “block” is stacked above each point on a regular grid. As the top two panels show, however, the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution. If we instead center each block on the point it represents, we get the estimate shown in the bottom left panel. This is a kernel density estimation with a “top hat” kernel. This idea can be generalized to other kernel shapes: the bottom-right panel of the first figure shows a Gaussian kernel density estimate over the same distribution.

Scikit-learn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure, through the `sklearn.neighbors.KernelDensity` estimator. The available kernels are shown in the second figure of this example.

The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension. Though this example uses 1D distributions, kernel density estimation is easily and efficiently extensible to higher dimensions as well.

**6.22.13 Approximate nearest neighbors in TSNE**

This example presents how to chain KNeighborsTransformer and TSNE in a pipeline. It also shows how to wrap the packages annoy and nmslib to replace KNeighborsTransformer and perform approximate nearest neighbors. These packages can be installed with `pip install annoy nmslib`. 

---

**Note:** Click [here](#) to download the full example code or to run this example in your browser via Binder.
Note: Currently `TSNE(metric='precomputed')` does not modify the precomputed distances, and thus assumes that precomputed euclidean distances are squared. In future versions, a parameter in `TSNE` will control the optional squaring of precomputed distances (see #12401).

Note: In `KNeighborsTransformer` we use the definition which includes each training point as its own neighbor in the count of `n_neighbors`, and for compatibility reasons, one extra neighbor is computed when `mode == 'distance'`. Please note that we do the same in the proposed wrappers.

Sample output:

```python
Benchmarking on MNIST_2000:
---------------------------
AnnoyTransformer: 0.583 sec
NMSlibTransformer: 0.321 sec
KNeighborsTransformer: 1.225 sec
TSNE with AnnoyTransformer: 4.903 sec
TSNE with NMSlibTransformer: 5.009 sec
TSNE with KNeighborsTransformer: 6.210 sec
TSNE with internal NearestNeighbors: 6.365 sec

Benchmarking on MNIST_10000:
---------------------------
AnnoyTransformer: 4.457 sec
NMSlibTransformer: 2.080 sec
KNeighborsTransformer: 30.680 sec
TSNE with AnnoyTransformer: 30.225 sec
TSNE with NMSlibTransformer: 43.295 sec
TSNE with KNeighborsTransformer: 64.845 sec
TSNE with internal NearestNeighbors: 64.984 sec
```

```python
try:
    import annoy

### 6.23.1 Visualization of MLP weights on MNIST

Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior. For example if weights look unstructured, maybe some were not used at all, or if very large coefficients exist, maybe regularization was too low or the learning rate too high.

This example shows how to plot some of the first layer weights in a MLPClassifier trained on the MNIST dataset.

The input data consists of 28x28 pixel handwritten digits, leading to 784 features in the dataset. Therefore the first layer weight matrix have the shape (784, hidden_layer_sizes[0]). We can therefore visualize a single column of the weight matrix as a 28x28 pixel image.

To make the example run faster, we use very few hidden units, and train only for a very short time. Training longer would result in weights with a much smoother spatial appearance.

6.23.2 Restricted Boltzmann Machine features for digit classification

For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background, like handwritten digit recognition, the Bernoulli Restricted Boltzmann machine model (BernoulliRBM) can perform effective non-linear feature extraction.

In order to learn good latent representations from a small dataset, we artificially generate more labeled data by perturbing the training data with linear shifts of 1 pixel in each direction.

This example shows how to build a classification pipeline with a BernoulliRBM feature extractor and a LogisticRegression classifier. The hyperparameters of the entire model (learning rate, hidden layer size, regularization) were optimized by grid search, but the search is not reproduced here because of runtime constraints.

Logistic regression on raw pixel values is presented for comparison. The example shows that the features extracted by the BernoulliRBM help improve the classification accuracy.

100 components extracted by RBM

![Images of extracted components]

## 6.23.3 Varying regularization in Multi-layer Perceptron

A comparison of different values for regularization parameter ‘alpha’ on synthetic datasets. The plot shows that different alphas yield different decision functions.

Alpha is a parameter for regularization term, aka penalty term, that combats overfitting by constraining the size of the weights. Increasing alpha may fix high variance (a sign of overfitting) by encouraging smaller weights, resulting in a decision boundary plot that appears with lesser curvatures. Similarly, decreasing alpha may fix high bias (a sign of underfitting) by encouraging larger weights, potentially resulting in a more complicated decision boundary.

### 6.23.4 Compare Stochastic learning strategies for MLPClassifier

This example visualizes some training loss curves for different stochastic learning strategies, including SGD and Adam. Because of time-constraints, we use several small datasets, for which L-BFGS might be more suitable. The general trend shown in these examples seems to carry over to larger datasets, however.

Note that those results can be highly dependent on the value of `learning_rate_init`.

```
import matplotlib.pyplot as plt
import numpy as np
import sklearn

# Fixing random state for reproducibility
np.random.seed(1)

# We want 30% of each class in each minibatch, so we use stratified sampling
uniform = sklearn.utils.shuffle.

# We split our data into training and testing sets...

# ...and then into training, validation, and test sets.

# To train our models, we use the stochastic learning strategy of our choice.

# In this case, we use the 'adam' strategy.

# We then evaluate our models on the test set.

# We can then compare the performance of our models on the test set.

# Here, we see that the 'adam' strategy performs better than the 'sgd' strategy.

# We can also compare the performance of our models on the training set.

# Here, we see that the 'adam' strategy performs better than the 'sgd' strategy.

6.24 Pipelines and composite estimators

Examples of how to compose transformers and pipelines from other estimators. See the User Guide.

Note: Click here to download the full example code or to run this example in your browser via Binder

6.24.1 Concatenating multiple feature extraction methods

In many real-world examples, there are many ways to extract features from a dataset. Often it is beneficial to combine several methods to obtain good performance. This example shows how to use FeatureUnion to combine features obtained by PCA and univariate selection.

Combining features using this transformer has the benefit that it allows cross validation and grid searches over the whole process.

The combination used in this example is not particularly helpful on this dataset and is only used to illustrate the usage of FeatureUnion.

Out:

Combined space has 3 features

6.24. Pipelines and composite estimators 1425
### Example: Cross-Validation with Various Parameters

The following code snippet demonstrates the use of cross-validation with various parameters for a machine learning model. It shows how to evaluate the model's performance under different conditions, specifically focusing on the impact of parameter adjustments on the model's accuracy.

```python
from sklearn.model_selection import cross_val_score
from sklearn.svm import SVC
from sklearn.decomposition import PCA
from sklearn.feature_selection import SelectKBest, f_classif

# Define the SVM model with PCA and feature selection
svm = SVC(C=1)
pca = PCA(n_components=2)
univ_select = SelectKBest(f_classif, k=1)

# Cross-validation with different parameter combinations
parameters = [(2, 1), (2, 10), (2, 10), (2, 10), (2, 10), (2, 10), (2, 10)]
for n_components, k in parameters:
    svm.set_params(features__pca__n_components=n_components)
    univ_select.set_params(features__univ_select__k=k)
    scores = cross_val_score(svm, X, y, cv=5)
    print(f'features__pca__n_components={n_components}, features__univ_select__k={k}, svm__C=1, score={scores.mean()}.
    total={scores.var()}')
```

This example illustrates how to systematically evaluate model performance under various combinations of parameters, which is crucial for fine-tuning models to achieve optimal performance.

ax0.legend(prop=dict(size=12))

# For each number of components, find the best classifier results
results = pd.DataFrame(search.cv_results_)
components_col = 'param_pca__n_components'
best_clfs = results.groupby(components_col).apply(lambda g: g.nlargest(1, 'mean_test_score'))
best_clfs.plot(x=components_col, y='mean_test_score', yerr='std_test_score', legend=False, ax=ax1)
ax1.set_ylabel('Classification accuracy (val)')
ax1.set_xlabel('n_components')

plt.xlim(-1, 70)
plt.tight_layout()
plt.show()
6.24.3 Column Transformer with Mixed Types

This example illustrates how to apply different preprocessing and feature extraction pipelines to different subsets of features, using `sklearn.compose.ColumnTransformer`. This is particularly handy for the case of datasets that contain heterogeneous data types, since we may want to scale the numeric features and one-hot encode the categorical ones.

In this example, the numeric data is standard-scaled after mean-imputation, while the categorical data is one-hot encoded after imputing missing values with a new category ('missing').

Finally, the preprocessing pipeline is integrated in a full prediction pipeline using `sklearn.pipeline.Pipeline`, together with a simple classification model.

```python
# Author: Pedro Morales <part.morales@gmail.com>
#
# License: BSD 3 clause

import numpy as np

from sklearn.compose import ColumnTransformer
from sklearn.datasets import fetch_openml
from sklearn.pipeline import Pipeline
from sklearn.impute import SimpleImputer
from sklearn.preprocessing import StandardScaler, OneHotEncoder
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split, GridSearchCV

np.random.seed(0)

# Load data from https://www.openml.org/d/40945
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)

# Alternatively X and y can be obtained directly from the frame attribute:
# X = titanic.frame.drop('survived', axis=1)
# y = titanic.frame['survived']

# We will train our classifier with the following features:
# Numeric Features:
# - age: float.
# - fare: float.
# Categorical Features:
# - embarked: categories encoded as strings {'C', 'S', 'Q'}.
# - sex: categories encoded as strings {'female', 'male'}.
# - pclass: ordinal integers {1, 2, 3}.

# We create the preprocessing pipelines for both numeric and categorical data.
numeric_features = ['age', 'fare']
numeric_transformer = Pipeline(steps=[
    ('imputer', SimpleImputer(strategy='median')),
    ('scaler', StandardScaler())])
```
categorical_features = ['embarked', 'sex', 'pclass']
categorical_transformer = Pipeline(steps=[
    ('imputer', SimpleImputer(strategy='constant', fill_value='missing')),
    ('onehot', OneHotEncoder(handle_unknown='ignore'))
])

preprocessor = ColumnTransformer(
    transformers=[
        ('num', numeric_transformer, numeric_features),
        ('cat', categorical_transformer, categorical_features)])

# Append classifier to preprocessing pipeline.
# Now we have a full prediction pipeline.
clf = Pipeline(steps=[('preprocessor', preprocessor),
                     ('classifier', LogisticRegression())])

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2)

clf.fit(X_train, y_train)
print("model score: %.3f" % clf.score(X_test, y_test))

Out:

model score: 0.790

Using the prediction pipeline in a grid search

Grid search can also be performed on the different preprocessing steps defined in the ColumnTransformer object, together with the classifier’s hyperparameters as part of the Pipeline. We will search for both the imputer strategy of the numeric preprocessing and the regularization parameter of the logistic regression using sklearn.model_selection.GridSearchCV.

param_grid = {
    'preprocessor__num__imputer__strategy': ['mean', 'median'],
    'classifier__C': [0.1, 1.0, 10, 100],
}

grid_search = GridSearchCV(clf, param_grid, cv=10)
grid_search.fit(X_train, y_train)

print("best logistic regression from grid search: %.3f" % grid_search.score(X_test, y_test))

Out:

best logistic regression from grid search: 0.798

Total running time of the script: ( 0 minutes 3.337 seconds)
Estimated memory usage: 8 MB

Note: Click here to download the full example code or to run this example in your browser via Binder
6.24.4 Selecting dimensionality reduction with Pipeline and GridSearchCV

This example constructs a pipeline that does dimensionality reduction followed by prediction with a support vector classifier. It demonstrates the use of GridSearchCV and Pipeline to optimize over different classes of estimators in a single CV run – unsupervised PCA and NMF dimensionality reductions are compared to univariate feature selection during the grid search.

Additionally, Pipeline can be instantiated with the `memory` argument to memoize the transformers within the pipeline, avoiding to fit again the same transformers over and over.

Note that the use of `memory` to enable caching becomes interesting when the fitting of a transformer is costly.

Illustration of Pipeline and GridSearchCV

This section illustrates the use of a Pipeline with GridSearchCV

```python
# Authors: Robert McGibbon, Joel Nothman, Guillaume Lemaitre

import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import load_digits
from sklearn.model_selection import GridSearchCV
from sklearn.pipeline import Pipeline
from sklearn.svm import LinearSVC
from sklearn.decomposition import PCA, NMF
from sklearn.feature_selection import SelectKBest, chi2

print(__doc__)

pipe = Pipeline([  
    ('reduce_dim', 'passthrough'),
    ('classify', LinearSVC(dual=False, max_iter=10000))
])

N_FEATURES_OPTIONS = [2, 4, 8]
C_OPTIONS = [1, 10, 100, 1000]
param_grid = [
    {'reduce_dim': [PCA(iterated_power=7), NMF()]
     'reduce_dim__n_components': N_FEATURES_OPTIONS,
     'classify__C': C_OPTIONS
    },
    {'reduce_dim': [SelectKBest(chi2)]
     'reduce_dim__k': N_FEATURES_OPTIONS,
     'classify__C': C_OPTIONS
    },
]
reducer_labels = ['PCA', 'NMF', 'KBest(chi2)']

grid = GridSearchCV(pipe, n_jobs=1, param_grid=param_grid)
X, y = load_digits(return_X_y=True)
grid.fit(X, y)

mean_scores = np.array(grid.cv_results_['mean_test_score'])
```

(continues on next page)
scores are in the order of param_grid iteration, which is alphabetical
mean_scores = mean_scores.reshape(len(C_OPTIONS), -1, len(N_FEATURES_OPTIONS))
# select score for best C
mean_scores = mean_scores.max(axis=0)
bar_offsets = (np.arange(len(N_FEATURES_OPTIONS)) *
               (len(reducer_labels) + 1) + .5)

plt.figure()
COLORS = 'bgrcmyk'
for i, (label, reducer_scores) in enumerate(zip(reducer_labels, mean_scores)):
    plt.bar(bar_offsets + i, reducer_scores, label=label, color=COLORS[i])

plt.title("Comparing feature reduction techniques")
plt.xlabel('Reduced number of features')
plt.ylabel('Digit classification accuracy')
plt.legend(loc='upper left')
plt.show()
**Caching transformers within a Pipeline**

It is sometimes worthwhile storing the state of a specific transformer since it could be used again. Using a pipeline in `GridSearchCV` triggers such situations. Therefore, we use the argument `memory` to enable caching.

**Warning:** Note that this example is, however, only an illustration since for this specific case fitting `PCA` is not necessarily slower than loading the cache. Hence, use the `memory` constructor parameter when the fitting of a transformer is costly.

```python
from joblib import Memory
from shutil import rmtree

# Create a temporary folder to store the transformers of the pipeline
location = 'cachedir'
memory = Memory(location=location, verbose=10)
cached_pipe = Pipeline([('reduce_dim', PCA()),
                        ('classify', LinearSVC(dual=False, max_iter=10000))],
                        memory=memory)

# This time, a cached pipeline will be used within the grid search

# Delete the temporary cache before exiting
memory.clear(warn=False)
rmtree(location)
```

The `PCA` fitting is only computed at the evaluation of the first configuration of the `C` parameter of the `LinearSVC` classifier. The other configurations of `C` will trigger the loading of the cached `PCA` estimator data, leading to save processing time. Therefore, the use of caching the pipeline using `memory` is highly beneficial when fitting a transformer is costly.

**Total running time of the script:** (0 minutes 5.862 seconds)

**Estimated memory usage:** 8 MB

**Note:** Click [here](#) to download the full example code or to run this example in your browser via Binder

---

### 6.24.5 Column Transformer with Heterogeneous Data Sources

Datasets can often contain components of that require different feature extraction and processing pipelines. This scenario might occur when:

1. Your dataset consists of heterogeneous data types (e.g. raster images and text captions)
2. Your dataset is stored in a Pandas DataFrame and different columns require different processing pipelines.

This example demonstrates how to use `sklearn.compose.ColumnTransformer` on a dataset containing different types of features. We use the 20-newsgroups dataset and compute standard bag-of-words features for the subject line and body in separate pipelines as well as ad hoc features on the body. We combine them (with weights) using a `ColumnTransformer` and finally train a classifier on the combined set of features.

The choice of features is not particularly helpful, but serves to illustrate the technique.

6.24.6 Effect of transforming the targets in regression model

In this example, we give an overview of the `sklearn.compose.TransformedTargetRegressor`. Two examples illustrate the benefit of transforming the targets before learning a linear regression model. The first example uses synthetic data while the second example is based on the Boston housing data set.

```python
# Author: Guillaume Lemaitre <guillaume.lemaitre@inria.fr>
# License: BSD 3 clause

import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from distutils.version import LooseVersion

print(__doc__)

Synthetic example

```python
from sklearn.datasets import make_regression
from sklearn.model_selection import train_test_split
from sklearn.linear_model import RidgeCV
from sklearn.compose import TransformedTargetRegressor
from sklearn.metrics import median_absolute_error, r2_score

# `normed` is being deprecated in favor of `density` in histograms
if LooseVersion(matplotlib.__version__) >= '2.1':
    density_param = {'density': True}
else:
    density_param = {'normed': True}
```
A synthetic random regression problem is generated. The targets $y$ are modified by: (i) translating all targets such that all entries are non-negative and (ii) applying an exponential function to obtain non-linear targets which cannot be fitted using a simple linear model.

Therefore, a logarithmic ($\text{np.log1p}$) and an exponential function ($\text{np.expm1}$) will be used to transform the targets before training a linear regression model and using it for prediction.

```python
X, y = make_regression(n_samples=10000, noise=100, random_state=0)
y = np.exp((y + abs(y.min())) / 200)
y_trans = np.log1p(y)
```

The following illustrate the probability density functions of the target before and after applying the logarithmic functions.

```python
f, (ax0, ax1) = plt.subplots(1, 2)
ax0.hist(y, bins=100, **density_param)
ax0.set_xlim([0, 2000])
ax0.set_ylabel('Probability')
ax0.set_xlabel('Target')
ax0.set_title('Target distribution')

ax1.hist(y_trans, bins=100, **density_param)
ax1.set_ylabel('Probability')
ax1.set_xlabel('Target')
ax1.set_title('Transformed target distribution')

f.suptitle("Synthetic data", y=0.035)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])

X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
```
At first, a linear model will be applied on the original targets. Due to the non-linearity, the model trained will not be precise during the prediction. Subsequently, a logarithmic function is used to linearize the targets, allowing better prediction even with a similar linear model as reported by the median absolute error (MAE).

```python
f, (ax0, ax1) = plt.subplots(1, 2, sharey=True)
regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)
ax0.scatter(y_test, y_pred)
ax0.plot([0, 2000], [0, 2000], '--k')
ax0.set_ylabel('Target predicted')
ax0.set_xlabel('True Target')
ax0.set_title('Ridge regression
without target transformation')
ax0.text(100, 1750, r'$R^2$=%.2f, MAE=%.2f' % (r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax0.set_xlim([0, 2000])
ax0.set_ylim([0, 2000])

regr_trans = TransformedTargetRegressor(regressor=RidgeCV(),
                                       func=np.log1p,
                                       inverse_func=np.expm1)
regr_trans.fit(X_train, y_train)
y_pred = regr_trans.predict(X_test)
```

Synthetic data

6.24. Pipelines and composite estimators 1441
Ridge regression
without target transformation

\[ R^2 = 0.41, \text{MAE} = 67.48 \]

Ridge regression
with target transformation

\[ R^2 = 0.65, \text{MAE} = 22.76 \]

Real-world data set

In a similar manner, the boston housing data set is used to show the impact of transforming the targets before learning a model. In this example, the targets to be predicted corresponds to the weighted distances to the five Boston employment centers.

```python
from sklearn.datasets import load_boston
from sklearn.preprocessing import QuantileTransformer, quantile_transform

dataset = load_boston()
```
A `sklearn.preprocessing.QuantileTransformer` is used such that the targets follows a normal distribution before applying a `sklearn.linear_model.RidgeCV` model.
The effect of the transformer is weaker than on the synthetic data. However, the transform induces a decrease of the MAE.

```python
f, (ax0, ax1) = plt.subplots(1, 2, sharey=True)
regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)

ax0.scatter(y_test, y_pred)
ax0.plot([0, 10], [0, 10], '--k')
ax0.set_ylabel('Target predicted')
ax0.set_xlabel('True Target')
ax0.set_title('Ridge regression without target transformation')
ax0.text(1, 9, r'$R^2$= %.2f, MAE= %.2f

regr_trans = TransformedTargetRegressor(
    regressor=RidgeCV(),
    transformer=QuantileTransformer(n_quantiles=300,
                                     output_distribution='normal'))
regr_trans.fit(X_train, y_train)
y_pred = regr_trans.predict(X_test)
```

Boston housing data: distance to employment centers

The effect of the transformer is weaker than on the synthetic data. However, the transform induces a decrease of the MAE.
ax1.scatter(y_test, y_pred)
ax1.plot([0, 10], [0, 10], '--k')
ax1.set_ylabel('Target predicted')
ax1.set_xlabel('True Target')
ax1.set_title('Ridge regression
with target transformation')
ax1.text(1, 9, r'$R^2$= %.2f, MAE= %.2f' % (
    r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax1.set_xlim([0, 10])
ax1.set_ylim([0, 10])

f.suptitle("Boston housing data: distance to employment centers", y=0.035)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])

plt.show()

Boston housing data: distance to employment centers

Total running time of the script: 0 minutes 3.786 seconds
Estimated memory usage: 10 MB

6.25 Preprocessing

Examples concerning the sklearn.preprocessing module.
6.25.1 Using FunctionTransformer to select columns

Shows how to use a function transformer in a pipeline. If you know your dataset’s first principle component is irrelevant for a classification task, you can use the FunctionTransformer to select all but the first column of the PCA transformed data.
import matplotlib.pyplot as plt
import numpy as np

from sklearn.model_selection import train_test_split
from sklearn.decomposition import PCA
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import FunctionTransformer

def _generate_vector(shift=0.5, noise=15):
    return np.arange(1000) + (np.random.rand(1000) - shift) * noise

def generate_dataset():
    """
    This dataset is two lines with a slope ~ 1, where one has
    a y offset of ~100
    """
    return np.vstack((
        np.vstack((
            _generate_vector(),
            _generate_vector() + 100,
        )).T,
        np.vstack((
            _generate_vector(),
            _generate_vector(),
        )).T,
    ))
\[ \text{np.hstack((np.zeros(1000), np.ones(1000)))} \]

```python
def all_but_first_column(X):
    return X[:, 1:]

def drop_first_component(X, y):
    
    Create a pipeline with PCA and the column selector and use it to transform the dataset.
    
    pipeline = make_pipeline(PCA(), FunctionTransformer(all_but_first_column),)
    X_train, X_test, y_train, y_test = train_test_split(X, y)
    pipeline.fit(X_train, y_train)
    return pipeline.transform(X_test), y_test

if __name__ == '__main__':
    X, y = generate_dataset()
    lw = 0
    plt.figure()
    plt.scatter(X[:, 0], X[:, 1], c=y, lw=lw)
    plt.figure()
    X_transformed, y_transformed = drop_first_component(*generate_dataset())
    plt.scatter(
        X_transformed[:, 0],
        np.zeros(len(X_transformed)),
        c=y_transformed,
        lw=lw,
        s=60
    )
    plt.show()
```

## 6.25.2 Using KBinsDiscretizer to discretize continuous features

The example compares prediction result of linear regression (linear model) and decision tree (tree based model) with and without discretization of real-valued features.

As is shown in the result before discretization, linear model is fast to build and relatively straightforward to interpret, but can only model linear relationships, while decision tree can build a much more complex model of the data. One way to make linear model more powerful on continuous data is to use discretization (also known as binning). In the example, we discretize the feature and one-hot encode the transformed data. Note that if the bins are not reasonably wide, there would appear to be a substantially increased risk of overfitting, so the discretizer parameters should usually be tuned under cross validation.

After discretization, linear regression and decision tree make exactly the same prediction. As features are constant
within each bin, any model must predict the same value for all points within a bin. Compared with the result before discretization, linear model become much more flexible while decision tree gets much less flexible. Note that binning features generally has no beneficial effect for tree-based models, as these models can learn to split up the data anywhere.

```python
# Author: Andreas Müller

import numpy as np
import matplotlib.pyplot as plt
from sklearn.linear_model import LinearRegression
from sklearn.preprocessing import KBinsDiscretizer
from sklearn.tree import DecisionTreeRegressor

print(__doc__)

# construct the dataset
rnd = np.random.RandomState(42)
X = rnd.uniform(-3, 3, size=100)
y = np.sin(X) + rnd.normal(size=len(X)) / 3
X = X.reshape(-1, 1)

# transform the dataset with KBinsDiscretizer
enc = KBinsDiscretizer(n_bins=10, encode='onehot')
X_binned = enc.fit_transform(X)

# predict with original dataset
fig, (ax1, ax2) = plt.subplots(ncols=2, sharey=True, figsize=(10, 4))
line = np.linspace(-3, 3, 1000, endpoint=False).reshape(-1, 1)
reg = LinearRegression().fit(X, y)
ax1.plot(line, reg.predict(line), linewidth=2, color='green',
        label="linear regression")
reg = DecisionTreeRegressor(min_samples_split=3, random_state=0).fit(X, y)
ax1.plot(line, reg.predict(line), linewidth=2, color='red',
        label="decision tree")
ax1.plot(X[:, 0], y, 'o', c='k')
ax1.legend(loc="best")
ax1.set_ylabel("Regression output")

# predict with discretized dataset
reg = LinearRegression().fit(X_binned, y)
ax2.plot(line, reg.predict(line), linewidth=2, color='green',
        label="linear regression")
reg = DecisionTreeRegressor(min_samples_split=3, random_state=0).fit(X_binned, y)
ax2.plot(line, reg.predict(line), linewidth=2, color='red',
        label="decision tree")
ax2.plot(X_binned[:, 0], y, 'o', c='k')
ax2.legend(loc="best")
ax2.set_ylabel("Regression output")
```

(continues on next page)
6.25.3 Demonstrating the different strategies of KBinsDiscretizer

This example presents the different strategies implemented in KBinsDiscretizer:

- **'uniform'**: The discretization is uniform in each feature, which means that the bin widths are constant in each dimension.

- **'quantile'**: The discretization is done on the quantiled values, which means that each bin has approximately the same number of samples.

- **'kmeans'**: The discretization is based on the centroids of a KMeans clustering procedure.

The plot shows the regions where the discretized encoding is constant.
# Author: Tom Dupré la Tour
# License: BSD 3 clause

```python
import numpy as np
import matplotlib.pyplot as plt

from sklearn.preprocessing import KBinsDiscretizer
from sklearn.datasets import make_blobs

print(__doc__)

strategies = ['uniform', 'quantile', 'kmeans']

n_samples = 200
centers_0 = np.array([[0, 0], [0, 5], [2, 4], [8, 8]])
centers_1 = np.array([[0, 0], [3, 1]])

# construct the datasets
random_state = 42
X_list = [
    np.random.RandomState(random_state).uniform(-3, 3, size=(n_samples, 2)),
    make_blobs(n_samples=[n_samples // 10, n_samples * 4 // 10, n_samples // 10, n_samples * 4 // 10],

6.25.4 Importance of Feature Scaling

Feature scaling through standardization (or Z-score normalization) can be an important preprocessing step for many machine learning algorithms. Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one.

While many algorithms (such as SVM, K-nearest neighbors, and logistic regression) require features to be normalized, intuitively we can think of Principle Component Analysis (PCA) as being a prime example of when normalization is important. In PCA we are interested in the components that maximize the variance. If one component (e.g. human height) varies less than another (e.g. weight) because of their respective scales (meters vs. kilos), PCA might determine that the direction of maximal variance more closely corresponds with the 'weight' axis, if those features are not scaled. As a change in height of one meter can be considered much more important than the change in weight of one kilogram, this is clearly incorrect.

To illustrate this, PCA is performed comparing the use of data with StandardScaler applied, to unscaled data. The results are visualized and a clear difference noted. The 1st principal component in the unscaled set can be seen. It can be seen that feature #13 dominates the direction, being a whole two orders of magnitude above the other features. This is contrasted when observing the principal component for the scaled version of the data. In the scaled version, the orders of magnitude are roughly the same across all the features.

The dataset used is the Wine Dataset available at UCI. This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure (i.e alcohol content, and malic acid).

The transformed data is then used to train a naive Bayes classifier, and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version.

Out:
Prediction accuracy for the normal test dataset with PCA
81.48%

Prediction accuracy for the standardized test dataset with PCA
98.15%

PC 1 without scaling:

6.25.5 Map data to a normal distribution

This example demonstrates the use of the Box-Cox and Yeo-Johnson transforms through `PowerTransformer` to map data from various distributions to a normal distribution.

The power transform is useful as a transformation in modeling problems where homoscedasticity and normality are desired. Below are examples of Box-Cox and Yeo-Johnson applied to six different probability distributions: Lognormal, Chi-squared, Weibull, Gaussian, Uniform, and Bimodal.

Note that the transformations successfully map the data to a normal distribution when applied to certain datasets, but are ineffective with others. This highlights the importance of visualizing the data before and after transformation.

Also note that even though Box-Cox seems to perform better than Yeo-Johnson for lognormal and chi-squared distributions, keep in mind that Box-Cox does not support inputs with negative values.

For comparison, we also add the output from `QuantileTransformer`. It can force any arbitrary distribution into a gaussian, provided that there are enough training samples (thousands). Because it is a non-parametric method, it is harder to interpret than the parametric ones (Box-Cox and Yeo-Johnson).

On “small” datasets (less than a few hundred points), the quantile transformer is prone to overfitting. The use of the power transform is then recommended.

6.25.6 Feature discretization

A demonstration of feature discretization on synthetic classification datasets. Feature discretization decomposes each feature into a set of bins, here equally distributed in width. The discrete values are then one-hot encoded, and given to a linear classifier. This preprocessing enables a non-linear behavior even though the classifier is linear.

On this example, the first two rows represent linearly non-separable datasets (moons and concentric circles) while the third is approximately linearly separable. On the two linearly non-separable datasets, feature discretization largely increases the performance of linear classifiers. On the linearly separable dataset, feature discretization decreases the performance of linear classifiers. Two non-linear classifiers are also shown for comparison.

This example should be taken with a grain of salt, as the intuition conveyed does not necessarily carry over to real datasets. Particularly in high-dimensional spaces, data can more easily be separated linearly. Moreover, using feature discretization and one-hot encoding increases the number of features, which easily lead to overfitting when the number of samples is small.

The plots show training points in solid colors and testing points semi-transparent. The lower right shows the classification accuracy on the test set.

6.25.7 Compare the effect of different scalers on data with outliers

Feature 0 (median income in a block) and feature 5 (number of households) of the California housing dataset have very different scales and contain some very large outliers. These two characteristics lead to difficulties to visualize the data and, more importantly, they can degrade the predictive performance of many machine learning algorithms. Unscaled data can also slow down or even prevent the convergence of many gradient-based estimators.

Indeed many estimators are designed with the assumption that each feature takes values close to zero or more importantly that all features vary on comparable scales. In particular, metric-based and gradient-based estimators often assume approximately standardized data (centered features with unit variances). A notable exception are decision tree-based estimators that are robust to arbitrary scaling of the data.

This example uses different scalers, transformers, and normalizers to bring the data within a pre-defined range.

Scalers are linear (or more precisely affine) transformers and differ from each other in the way to estimate the parameters used to shift and scale each feature.

QuantileTransformer provides non-linear transformations in which distances between marginal outliers and inliers are shrunk. PowerTransformer provides non-linear transformations in which data is mapped to a normal distribution to stabilize variance and minimize skewness.

Unlike the previous transformations, normalization refers to a per sample transformation instead of a per feature transformation.

The following code is a bit verbose, feel free to jump directly to the analysis of the results.

                               label='Color mapping for values of y')
```

Original data

Each transformation is plotted showing two transformed features, with the left plot showing the entire dataset, and the right zoomed-in to show the dataset without the marginal outliers. A large majority of the samples are compacted to a specific range, [0, 10] for the median income and [0, 6] for the number of households. Note that there are some marginal outliers (some blocks have more than 1200 households). Therefore, a specific pre-processing can be very beneficial depending of the application. In the following, we present some insights and behaviors of those pre-processing methods in the presence of marginal outliers.

```python
make_plot(0)
```
StandardScaler

StandardScaler removes the mean and scales the data to unit variance. However, the outliers have an influence when computing the empirical mean and standard deviation which shrink the range of the feature values as shown in the left figure below. Note in particular that because the outliers on each feature have different magnitudes, the spread of the transformed data on each feature is very different: most of the data lie in the [-2, 4] range for the transformed median income feature while the same data is squeezed in the smaller [-0.2, 0.2] range for the transformed number of households.

StandardScaler therefore cannot guarantee balanced feature scales in the presence of outliers.

MinMaxScaler

MinMaxScaler rescales the data set such that all feature values are in the range [0, 1] as shown in the right panel below. However, this scaling compress all inliers in the narrow range [0, 0.005] for the transformed number of households.

As StandardScaler, MinMaxScaler is very sensitive to the presence of outliers.
MaxAbsScaler

MaxAbsScaler differs from the previous scaler such that the absolute values are mapped in the range [0, 1]. On positive only data, this scaler behaves similarly to MinMaxScaler and therefore also suffers from the presence of large outliers.

RobustScaler

Unlike the previous scalers, the centering and scaling statistics of this scaler are based on percentiles and are therefore not influenced by a few number of very large marginal outliers. Consequently, the resulting range of the transformed feature values is larger than for the previous scalers and, more importantly, are approximately similar; for both features most of the transformed values lie in a [-2, 3] range as seen in the zoomed-in figure. Note that the outliers themselves are still present in the transformed data. If a separate outlier clipping is desirable, a non-linear transformation is required (see below).
PowerTransformer

PowerTransformer applies a power transformation to each feature to make the data more Gaussian-like. Currently, PowerTransformer implements the Yeo-Johnson and Box-Cox transforms. The power transform finds the optimal scaling factor to stabilize variance and minimize skewness through maximum likelihood estimation. By default, PowerTransformer also applies zero-mean, unit variance normalization to the transformed output. Note that Box-Cox can only be applied to strictly positive data. Income and number of households happen to be strictly positive, but if negative values are present the Yeo-Johnson transformed is to be preferred.

make_plot(5)
make_plot(6)
QuantileTransformer (Gaussian output)

QuantileTransformer has an additional `output_distribution` parameter allowing to match a Gaussian distribution instead of a uniform distribution. Note that this non-parametric transformer introduces saturation artifacts for extreme values.

```
make_plot(7)
```

QuantileTransformer (uniform output)

QuantileTransformer applies a non-linear transformation such that the probability density function of each feature will be mapped to a uniform distribution. In this case, all the data will be mapped in the range [0, 1], even the outliers which cannot be distinguished anymore from the inliers.

As RobustScaler, QuantileTransformer is robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation on held out data. But contrary to RobustScaler, QuantileTransformer will also automatically collapse any outlier by setting them to the a priori defined range boundaries (0 and 1).

```
make_plot(8)
```
Normalizer

The Normalizer rescales the vector for each sample to have unit norm, independently of the distribution of the samples. It can be seen on both figures below where all samples are mapped onto the unit circle. In our example the two selected features have only positive values; therefore the transformed data only lie in the positive quadrant. This would not be the case if some original features had a mix of positive and negative values.

```python
make_plot(9)
plt.show()
```

Total running time of the script: ( 0 minutes 12.243 seconds)
Estimated memory usage: 8 MB

6.26 Release Highlights

These examples illustrate the main features of the releases of scikit-learn.

Note: Click here to download the full example code or to run this example in your browser via Binder
6.26.1 Release Highlights for scikit-learn 0.22

We are pleased to announce the release of scikit-learn 0.22, which comes with many bug fixes and new features! We detail below a few of the major features of this release. For an exhaustive list of all the changes, please refer to the release notes.

To install the latest version (with pip):

```
pip install --upgrade scikit-learn
```

or with conda:

```
conda install scikit-learn
```

New plotting API

A new plotting API is available for creating visualizations. This new API allows for quickly adjusting the visuals of a plot without involving any recomputation. It is also possible to add different plots to the same figure. The following example illustrates `plot_roc_curve`, but other plots utilities are supported like `plot_partial_dependence`, `plot_precision_recall_curve`, and `plot_confusion_matrix`. Read more about this new API in the User Guide.

```python
from sklearn.model_selection import train_test_split
from sklearn.svm import SVC
from sklearn.metrics import plot_roc_curve
from sklearn.ensemble import RandomForestClassifier
from sklearn.datasets import make_classification
import matplotlib.pyplot as plt

X, y = make_classification(random_state=0)
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)

svc = SVC(random_state=42)
svc.fit(X_train, y_train)
rfc = RandomForestClassifier(random_state=42)
rfc.fit(X_train, y_train)

svc_disp = plot_roc_curve(svc, X_test, y_test)
rfc_disp = plot_roc_curve(rfc, X_test, y_test, ax=svc_disp.ax_)
rfc_disp.figure_.suptitle("ROC curve comparison")

plt.show()
```
Stacking Classifier and Regressor

StackingClassifier and StackingRegressor allow you to have a stack of estimators with a final classifier or a regressor. Stacked generalization consists in stacking the output of individual estimators and use a classifier to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator. Base estimators are fitted on the full X while the final estimator is trained using cross-validated predictions of the base estimators using cross_val_predict.

Read more in the User Guide.

```python
from sklearn.datasets import load_iris
from sklearn.svm import LinearSVC
from sklearn.linear_model import LogisticRegression
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline
from sklearn.ensemble import StackingClassifier
from sklearn.model_selection import train_test_split

X, y = load_iris(return_X_y=True)
estimators = [
    ('rf', RandomForestClassifier(n_estimators=10, random_state=42)),
    ('svr', make_pipeline(StandardScaler(),
                          LinearSVC(random_state=42)))
]
```

(continues on next page)
clf = StackingClassifier(
    estimators=estimators, final_estimator=LogisticRegression()
)
X_train, X_test, y_train, y_test = train_test_split(
    X, y, stratify=y, random_state=42
)
clf.fit(X_train, y_train).score(X_test, y_test)

Out:
0.9473684210526315

### Permutation-based feature importance

The `inspection.permutation_importance` can be used to get an estimate of the importance of each feature, for any fitted estimator:

```python
from sklearn.ensemble import RandomForestClassifier
from sklearn.inspection import permutation_importance

X, y = make_classification(random_state=0, n_features=5, n_informative=3)
rf = RandomForestClassifier(random_state=0).fit(X, y)
result = permutation_importance(rf, X, y, n_repeats=10, random_state=0,
                                n_jobs=-1)

fig, ax = plt.subplots()
sorted_idx = result.importances_mean.argsort()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=range(X.shape[1]))
ax.set_title("Permutation Importance of each feature")
ax.set_ylabel("Features")
fig.tight_layout()
plt.show()
```
Native support for missing values for gradient boosting

The `ensemble.HistGradientBoostingClassifier` and `ensemble.HistGradientBoostingRegressor` now have native support for missing values (NaNs). This means that there is no need for imputing data when training or predicting.

```python
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingClassifier
import numpy as np

X = np.array([0, 1, 2, np.nan]).reshape(-1, 1)
y = [0, 0, 1, 1]

gbdt = HistGradientBoostingClassifier(min_samples_leaf=1).fit(X, y)
print(gbdt.predict(X))
```

Out:

```
[0 0 1 1]
```
**Precomputed sparse nearest neighbors graph**

Most estimators based on nearest neighbors graphs now accept precomputed sparse graphs as input, to reuse the same graph for multiple estimator fits. To use this feature in a pipeline, one can use the `memory` parameter, along with one of the two new transformers, `neighbors.KNeighborsTransformer` and `neighbors.RadiusNeighborsTransformer`. The precomputation can also be performed by custom estimators to use alternative implementations, such as approximate nearest neighbors methods. See more details in the User Guide.

```python
from tempfile import TemporaryDirectory
from sklearn.neighbors import KNeighborsTransformer
from sklearn.manifold import Isomap
from sklearn.pipeline import make_pipeline

X, y = make_classification(random_state=0)
with TemporaryDirectory(prefix="sklearn_cache_") as tmpdir:
    estimator = make_pipeline(
        KNeighborsTransformer(n_neighbors=10, mode='distance'),
        Isomap(n_neighbors=10, metric='precomputed'),
        memory=tmpdir)
    estimator.fit(X)

    # We can decrease the number of neighbors and the graph will not be recomputed.
    estimator.set_params(isomap__n_neighbors=5)
    estimator.fit(X)
```

**KNN Based Imputation**

We now support imputation for completing missing values using k-Nearest Neighbors.

Each sample's missing values are imputed using the mean value from `n_neighbors` nearest neighbors found in the training set. Two samples are close if the features that neither is missing are close. By default, a euclidean distance metric that supports missing values, `nan_euclidean_distances`, is used to find the nearest neighbors.

Read more in the User Guide.

```python
import numpy as np
from sklearn.impute import KNNImputer

X = [[1, 2, np.nan], [3, 4, 3], [np.nan, 6, 5], [8, 8, 7]]
imputer = KNNImputer(n_neighbors=2)
print(imputer.fit_transform(X))
```

Out:

```
[[1.  2.  4. ]
 [3.  4.  3. ]
 [5.5 6.  5. ]
 [8.  8.  7. ]]
```

**Tree pruning**

It is now possible to prune most tree-based estimators once the trees are built. The pruning is based on minimal cost-complexity. Read more in the User Guide for details.
X, y = make_classification(random_state=0)

rf = RandomForestClassifier(random_state=0, ccp_alpha=0).fit(X, y)
print("Average number of nodes without pruning {:.1f}".format(
    np.mean([e.tree_.node_count for e in rf.estimators_])))

rf = RandomForestClassifier(random_state=0, ccp_alpha=0.05).fit(X, y)
print("Average number of nodes with pruning {:.1f}".format(
    np.mean([e.tree_.node_count for e in rf.estimators_])))

Out:
Average number of nodes without pruning 22.3
Average number of nodes with pruning 6.4

Retrieve dataframes from OpenML

datasets.fetch_openml can now return pandas dataframe and thus properly handle datasets with heterogeneous data:

```python
from sklearn.datasets import fetch_openml
titanic = fetch_openml('titanic', version=1, as_frame=True)
print(titanic.data.head()[['pclass', 'embarked']])
```

Out:

<table>
<thead>
<tr>
<th>pclass</th>
<th>embarked</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
</tbody>
</table>

Checking scikit-learn compatibility of an estimator

Developers can check the compatibility of their scikit-learn compatible estimators using `check_estimator`. For instance, the `check_estimator(LinearSVC)` passes.

We now provide a `pytest` specific decorator which allows `pytest` to run all checks independently and report the checks that are failing.

```python
from sklearn.linear_model import LogisticRegression
from sklearn.tree import DecisionTreeRegressor
from sklearn.utils.estimator_checks import parametrize_with_checks

@parametrize_with_checks([LogisticRegression, DecisionTreeRegressor])
def test_sklearn_compatible_estimator(estimator, check):
    check(estimator)
```
**ROC AUC now supports multiclass classification**

The `roc_auc_score` function can also be used in multi-class classification. Two averaging strategies are currently supported: the one-vs-one algorithm computes the average of the pairwise ROC AUC scores, and the one-vs-rest algorithm computes the average of the ROC AUC scores for each class against all other classes. In both cases, the multiclass ROC AUC scores are computed from the probability estimates that a sample belongs to a particular class according to the model. The OvO and OvR algorithms support weighting uniformly (average='macro') and weighting by the prevalence (average='weighted').

Read more in the *User Guide*.

```python
from sklearn.datasets import make_classification
from sklearn.svm import SVC
from sklearn.metrics import roc_auc_score

X, y = make_classification(n_classes=4, n_informative=16)
clf = SVC(decision_function_shape='ovo', probability=True).fit(X, y)
print(roc_auc_score(y, clf.predict_proba(X), multi_class='ovo'))
```

Out:

0.9957333333333332

**Total running time of the script:** ( 0 minutes 5.414 seconds)

**Estimated memory usage:** 8 MB

### 6.27 Semi Supervised Classification

Examples concerning the `sklearn.semi_supervised` module.

**Note:** Click [here](#) to download the full example code or to run this example in your browser via Binder

#### 6.27.1 Decision boundary of label propagation versus SVM on the Iris dataset

Comparison for decision boundary generated on iris dataset between Label Propagation and SVM.

This demonstrates Label Propagation learning a good boundary even with a small amount of labeled data.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn import svm
from sklearn.semi_supervised import LabelSpreading

rng = np.random.RandomState(0)
iris = datasets.load_iris()

X = iris.data[:, :2]
y = iris.target

# step size in the mesh
h = .02

y_30 = np.copy(y)
y_30[rng.rand(len(y)) < 0.3] = -1
y_50 = np.copy(y)
y_50[rng.rand(len(y)) < 0.5] = -1

(continues on next page)
# we create an instance of SVM and fit out data. We do not scale our data since we want to plot the support vectors

```
ls30 = (LabelSpreading().fit(X, y_30), y_30)
ls50 = (LabelSpreading().fit(X, y_50), y_50)
ls100 = (LabelSpreading().fit(X, y), y)
rbf_svc = (svm.SVC(kernel='rbf', gamma=.5).fit(X, y), y)
```

# create a mesh to plot in
```
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h), np.arange(y_min, y_max, h))
```

titles = ['Label Spreading 30% data', 'Label Spreading 50% data', 'Label Spreading 100% data', 'SVC with rbf kernel']

color_map = {-1: (1, 1, 1), 0: (0, 0, .9), 1: (1, 0, 0), 2: (.8, .6, 0)}

```
for i, (clf, y_train) in enumerate((ls30, ls50, ls100, rbf_svc)):
    # Plot the decision boundary. For that, we will assign a color to each point in the mesh [x_min, x_max]x[y_min, y_max].
    plt.subplot(2, 2, i + 1)
    Z = clf.predict(np.c_[xx.ravel(), yy.ravel()]).reshape(xx.shape)
    plt.contourf(xx, yy, Z, cmap=plt.cm.Paired)
    plt.axis('off')
```

```
    # Plot also the training points
    colors = [color_map[y] for y in y_train]
    plt.scatter(X[:, 0], X[:, 1], c=colors, edgecolors='black')
    plt.title(titles[i])
```

```
plt.suptitle("Unlabeled points are colored white", y=0.1)
plt.show()
```

Total running time of the script: 0 minutes 0.850 seconds

Estimated memory usage: 79 MB

6.27.2 Label Propagation learning a complex structure

Example of LabelPropagation learning a complex internal structure to demonstrate “manifold learning”. The outer circle should be labeled “red” and the inner circle “blue”. Because both label groups lie inside their own distinct shape, we can see that the labels propagate correctly around the circle.
# Authors: Clay Woolam <clay@woolam.org>
# Andreas Mueller <amueller@ais.uni-bonn.de>
# License: BSD

```python
import numpy as np
import matplotlib.pyplot as plt
from sklearn.semi_supervised import LabelSpreading
from sklearn.datasets import make_circles

# generate ring with inner box
n_samples = 200
X, y = make_circles(n_samples=n_samples, shuffle=False)
outer, inner = 0, 1
labels = np.full(n_samples, -1.)
labels[0] = outer
labels[-1] = inner

# Learn with LabelSpreading
label_spread = LabelSpreading(kernel='knn', alpha=0.8)
label_spread.fit(X, labels)

# Plot output labels
output_labels = label_spread.transduction_
plt.figure(figsize=(8.5, 4))
plt.scatter(X[labels == outer, 0], X[labels == outer, 1], color='navy',
             marker='s', lw=0, label="outer labeled", s=10)
plt.scatter(X[labels == inner, 0], X[labels == inner, 1], color='c',
            marker='s', lw=0, label="inner labeled", s=10)
plt.scatter(X[labels == -1, 0], X[labels == -1, 1], color='darkorange',
            marker='.', label="unlabeled")
plt.legend(scatterpoints=1, shadow=False, loc='upper right')
plt.title("Raw data (2 classes=outer and inner)")
```

(continues on next page)
6.27.3 Label Propagation digits: Demonstrating performance

This example demonstrates the power of semisupervised learning by training a Label Spreading model to classify handwritten digits with sets of very few labels.

The handwritten digit dataset has 1797 total points. The model will be trained using all points, but only 30 will be labeled. Results in the form of a confusion matrix and a series of metrics over each class will be very good.

At the end, the top 10 most uncertain predictions will be shown.
Learning with small amount of labeled data

```
Out:

Label Spreading model: 40 labeled & 300 unlabeled points (340 total)

6.27.4 Label Propagation digits active learning

Demonstrates an active learning technique to learn handwritten digits using label propagation.

We start by training a label propagation model with only 10 labeled points, then we select the top five most uncertain points to label. Next, we train with 15 labeled points (original 10 + 5 new ones). We repeat this process four times to have a model trained with 30 labeled examples. Note you can increase this to label more than 30 by changing max_iterations. Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique.

A plot will appear showing the top 5 most uncertain digits for each iteration of training. These may or may not contain mistakes, but we will train the next model with their true labels.
### Iteration 0

6.28 Support Vector Machines

Examples concerning the `sklearn.svm` module.

Note: Click [here](#) to download the full example code or to run this example in your browser via Binder

6.28.1 Non-linear SVM

Perform binary classification using non-linear SVC with RBF kernel. The target to predict is a XOR of the inputs. The color map illustrates the decision function learned by the SVC.

```python
print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
```

(continues on next page)
xx, yy = np.meshgrid(np.linspace(-3, 3, 500),
                     np.linspace(-3, 3, 500))
np.random.seed(0)
X = np.random.randn(300, 2)
Y = np.logical_xor(X[:, 0] > 0, X[:, 1] > 0)

# fit the model
clf = svm.NuSVC(gamma='auto')
clf.fit(X, Y)

# plot the decision function for each datapoint on the grid
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
plt.imshow(Z, interpolation='nearest',
          extent=(xx.min(), xx.max(), yy.min(), yy.max()), aspect='auto',
          origin='lower', cmap=plt.cm.PuOr_r)
contours = plt.contour(xx, yy, Z, levels=[0], linewidths=2,
                       linestyles='dashed')
plt.scatter(X[:, 0], X[:, 1], s=30, c=Y, cmap=plt.cm.Paired,
            edgecolors='k')
plt.xticks(());
plt.yticks(());
plt.axis([-3, 3, -3, 3])
plt.show()
```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
from sklearn.datasets import make_blobs

# we create 40 separable points
X, y = make_blobs(n_samples=40, centers=2, random_state=6)

# fit the model, don't regularize for illustration purposes
clf = svm.SVC(kernel='linear', C=1000)
clf.fit(X, y)

plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)

# plot the decision function
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)
```

(continues on next page)

6.28.3 SVM with custom kernel

Simple usage of Support Vector Machines to classify a sample. It will plot the decision surface and the support vectors.

3-Class classification using Support Vector Machine with custom kernel
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm, datasets

# import some data to play with
iris = datasets.load_iris()
X = iris.data[:, :2]  # we only take the first two features. We could
                      # avoid this ugly slicing by using a two-dim dataset
Y = iris.target

def my_kernel(X, Y):
    """
    We create a custom kernel:

            [2  0]
    k(X, Y) = X [ ] Y.T
            [0  1]
    """
    M = np.array([[2, 0], [0, 1.0]])
    return np.dot(np.dot(X, M), Y.T)

h = .02  # step size in the mesh

# we create an instance of SVM and fit out data.
clf = svm.SVC(kernel=my_kernel)
clf.fit(X, Y)

# Plot the decision boundary. For that, we will assign a color to each
# point in the mesh [x_min, x_max]x[y_min, y_max].
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h), np.arange(y_min, y_max, h))
Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])

# Put the result into a color plot
Z = Z.reshape(xx.shape)
plt.pcolormesh(xx, yy, Z, cmap=plt.cm.Paired)

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=Y, cmap=plt.cm.Paired, edgecolors='k')
plt.title('3-Class classification using Support Vector Machine with custom'
         ' kernel')
plt.axis('tight')
plt.show()
6.28.4 Plot the support vectors in LinearSVC

Unlike SVC (based on LIBSVM), LinearSVC (based on LIBLINEAR) does not provide the support vectors. This example demonstrates how to obtain the support vectors in LinearSVC.

```python
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_blobs
from sklearn.svm import LinearSVC

X, y = make_blobs(n_samples=40, centers=2, random_state=0)
plt.figure(figsize=(10, 5))
for i, C in enumerate([1, 100]):  # "hinge" is the standard SVM loss
    # obtain the support vectors through the decision function
    decision_function = clf.decision_function(X)
    # we can also calculate the decision function manually
    # decision_function = np.dot(X, clf.coef_[0]) + clf.intercept_[0]
    support_vector_indices = np.where((2 * y - 1) * decision_function <= 1)[0]
    support_vectors = X[support_vector_indices]
    plt.subplot(1, 2, i + 1)
    plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)
    ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()
xx, yy = np.meshgrid(np.linspace(xlim[0], xlim[1], 50),
                     np.linspace(ylim[0], ylim[1], 50))
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])

plt.scatter(support_vectors[:, 0], support_vectors[:, 1], s=100,
            linewidth=1, facecolors='none', edgecolors='k')
```

(continues on next page)
6.28.5 SVM Tie Breaking Example

Tie breaking is costly if decision_function_shape='ovr', and therefore it is not enabled by default. This example illustrates the effect of the break_ties parameter for a multiclass classification problem and decision_function_shape='ovr'.

The two plots differ only in the area in the middle where the classes are tied. If break_ties=False, all input in that area would be classified as one class, whereas if break_ties=True, the tie-breaking mechanism will create a non-convex decision boundary in that area.
break_ties = False

break_ties = True

# Code source: Andreas Mueller, Adrin Jalali

print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn.svm import SVC
from sklearn.datasets import make_blobs

X, y = make_blobs(random_state=27)

fig, sub = plt.subplots(2, 1, figsize=(5, 8))
titles = ("break_ties = False",
"break_ties = True")

for break_ties, title, ax in zip((False, True), titles, sub.flatten()):
    svm = SVC(kernel="linear", C=1, break_ties=break_ties, decision_function_shape='ovr').fit(X, y)
    xlim = [X[:, 0].min(), X[:, 0].max()]
ylim = [X[:, 1].min(), X[:, 1].max()]
x = np.linspace(xlim[0], xlim[1], 1000)
y = np.linspace(ylim[0], ylim[1], 1000)

ax.imshow(-pred.reshape(xx.shape), cmap="Accent", alpha=.2, extent=(xlim[0], xlim[1], ylim[1], ylim[0]))

for coef, intercept, col in zip(svm.coef_, svm.intercept_, classes):
    line2 = -(line * coef[1] + intercept) / coef[0]
    ax.plot(line2, line, "--", c=colors[col[0]])
    ax.plot(line2, line, "--", c=colors[col[1]])

plt.show()
6.28.6 SVM: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.

The sample weighting rescales the C parameter, which means that the classifier puts more emphasis on getting these points right. The effect might often be subtle. To emphasize the effect here, we particularly weight outliers, making the deformation of the decision boundary very visible.

```python
print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

def plot_decision_function(classifier, sample_weight, axis, title):
    # plot the decision function
    xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))
    Z = classifier.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)

    # plot the line, the points, and the nearest vectors to the plane
    axis.contourf(xx, yy, Z, alpha=0.75, cmap=plt.cm.bone)
    axis.scatter(X[:, 0], X[:, 1], c=y, s=100 * sample_weight, alpha=0.9,
                 cmap=plt.cm.bone, edgecolors='black')

    axis.axis('off')
    axis.set_title(title)

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]
y = [1] * 10 + [-1] * 10
sample_weight_last_ten = abs(np.random.randn(len(X)))
sample_weight_constant = np.ones(len(X))
# and bigger weights to some outliers

### 6.28.9 SVM-Anova: SVM with univariate feature selection

This example shows how to perform univariate feature selection before running a SVC (support vector classifier) to improve the classification scores. We use the iris dataset (4 features) and add 36 non-informative features. We can find that our model achieves best performance when we select around 10% of features.
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import load_iris
from sklearn.feature_selection import SelectPercentile, chi2
from sklearn.model_selection import cross_val_score
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import StandardScaler
from sklearn.svm import SVC

# #############################################################################
# Import some data to play with
X, y = load_iris(return_X_y=True)
# Add non-informative features
np.random.seed(0)
X = np.hstack((X, 2 * np.random.random((X.shape[0], 36))))

# #############################################################################
# Create a feature-selection transform, a scaler and an instance of SVM that we
# combine together to have an full-blown estimator
clf = Pipeline([('anova', SelectPercentile(chi2)), ('scaler', StandardScaler()), ('svc', SVC(gamma="auto"))])
# Plot the cross-validation score as a function of percentile of features

```python
score_means = list()
score_stds = list()
percentiles = (1, 3, 6, 10, 15, 20, 30, 40, 60, 80, 100)

for percentile in percentiles:
    clf.set_params(anova__percentile=percentile)
    this_scores = cross_val_score(clf, X, y)
    score_means.append(this_scores.mean())
    score_stds.append(this_scores.std())

plt.errorbar(percentiles, score_means, np.array(score_stds))

6.28.11 SVM Margins Example

The plots below illustrate the effect the parameter C has on the separation line. A large value of C basically tells our model that we do not have that much faith in our data’s distribution, and will only consider points close to line of separation.

A small value of C includes more/all the observations, allowing the margins to be calculated using all the data in the area.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

# we create 40 separable points
np.random.seed(0)
X = np.r_[np.random.randn(20, 2) - [2, 2], np.random.randn(20, 2) + [2, 2]]
Y = [0] * 20 + [1] * 20

# figure number
fignum = 1

# fit the model
for name, penalty in [('unreg', 1), ('reg', 0.05)]:

    clf = svm.SVC(kernel='linear', C=penalty)
    clf.fit(X, Y)

    # get the separating hyperplane
    w = clf.coef_[0]
    a = -w[0] / w[1]
    xx = np.linspace(-5, 5)
    yy = a * xx - (clf.intercept_[0]) / w[1]

    # plot the parallels to the separating hyperplane that pass through the
    # support vectors (margin away from hyperplane in direction
    # perpendicular to hyperplane). This is sqrt(1+a^2) away vertically in
    # 2-d.
    margin = 1 / np.sqrt(np.sum(clf.coef_ ** 2))
    yy_down = yy - np.sqrt(1 + a ** 2) * margin
    yy_up = yy + np.sqrt(1 + a ** 2) * margin

    # plot the line, the points, and the nearest vectors to the plane
    plt.figure(fignum, figsize=(4, 3))
    plt.clf()
    plt.plot(xx, yy, 'k-')
    plt.plot(xx, yy_down, 'k--')
    plt.plot(xx, yy_up, 'k--')

    plt.scatter(clf.support_vectors_[:, 0], clf.support_vectors_[:, 1], s=80,
                facecolors='none', zorder=10, edgecolors='k')

6.28.13 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width

This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models LinearSVC() and SVC(kernel='linear') yield slightly different decision boundaries. This can be a consequence of the following differences:

- LinearSVC minimizes the squared hinge loss while SVC minimizes the regular hinge loss.
- LinearSVC uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while SVC uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

Note: while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don’t always generalize to more realistic high-dimensional problems.

6.28.14 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using Support Vector Machines for classification. For SVC classification, we are interested in a risk minimization for the equation:

$$ C \sum_{i=1,n} L(f(x_i), y_i) + \Omega(w) $$

where

- \( C \) is used to set the amount of regularization
- \( L \) is a loss function of our samples and our model parameters.
- \( \Omega \) is a penalty function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, cross validation, to set the amount of regularization with \( C \), there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.
Since our loss function is dependent on the amount of samples, the latter will influence the selected value of $C$. The question that arises is how do we optimally adjust $C$ to account for the different amount of training samples?

The figures below are used to illustrate the effect of scaling our $C$ to compensate for the change in the number of samples, in the case of using an $l_1$ penalty, as well as the $l_2$ penalty.

**l1-penalty case**

In the $l_1$ case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the $l_1$. It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling $C_1$.

**l2-penalty case**

The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

**Simulations**

The two figures below plot the values of $C$ on the $x$-axis and the corresponding cross-validation scores on the $y$-axis, for several different fractions of a generated data-set.

In the $l_1$ penalty case, the cross-validation-error correlates best with the test-error, when scaling our $C$ with the number of samples, $n$, which can be seen in the first figure.

For the $l_2$ penalty case, the best result comes from the case where $C$ is not scaled.

**Note:**

Two separate datasets are used for the two different plots. The reason behind this is the $l_1$ case works better on sparse data, while $l_2$ is better suited to the non-sparse case.

6.28.15 RBF SVM parameters

This example illustrates the effect of the parameters gamma and C of the Radial Basis Function (RBF) kernel SVM.

Intuitively, the gamma parameter defines how far the influence of a single training example reaches, with low values meaning ‘far’ and high values meaning ‘close’. The gamma parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

The C parameter trades off correct classification of training examples against maximization of the decision function’s margin. For larger values of C, a smaller margin will be accepted if the decision function is better at classifying all training points correctly. A lower C will encourage a larger margin, therefore a simpler decision function, at the cost of training accuracy. In other words ‘C’ behaves as a regularization parameter in the SVM.

The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier’s cross-validation accuracy as a function of C and gamma. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from $10^{-3}$ to $10^3$ is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye.

The behavior of the model is very sensitive to the gamma parameter. If gamma is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with C will be able to prevent overfitting.

When gamma is very small, the model is too constrained and cannot capture the complexity or “shape” of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

For intermediate values, we can see on the second plot that good models can be found on a diagonal of C and gamma. Smooth models (lower gamma values) can be made more complex by increasing the importance of classifying each point correctly (larger C values) hence the diagonal of good performing models.

Finally one can also observe that for some intermediate values of gamma we get equally performing models when C becomes very large: it is not necessary to regularize by enforcing a larger margin. The radius of the RBF kernel alone acts as a good structural regularizer. In practice though it might still be interesting to simplify the decision function with a lower value of C so as to favor models that use less memory and that are faster to predict.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations n_splits at the expense
of compute time. Increasing the value number of \texttt{C\_range} and \texttt{gamma\_range} steps will increase the resolution of the hyper-parameter heat map.
Out:

The best parameters are {'C': 1.0, 'gamma': 0.1} with a score of 0.97

6.29.4 Cross-validation on diabetes Dataset Exercise

A tutorial exercise which uses cross-validation with linear models.

This exercise is used in the Cross-validated estimators part of the Model selection: choosing estimators and their parameters section of the A tutorial on statistical-learning for scientific data processing.
Out:

Answer to the bonus question: how much can you trust the selection of alpha?

Alpha parameters maximising the generalization score on different subsets of the data:
[fold 0] alpha: 0.05968, score: 0.54209
[fold 1] alpha: 0.04520, score: 0.15523
[fold 2] alpha: 0.07880, score: 0.45193

Answer: Not very much since we obtained different alphas for different subsets of the data and moreover, the scores for these alphas differ quite substantially.

print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

from sklearn import datasets

### 6.30 Working with text documents

Examples concerning the `sklearn.feature_extraction.text` module.

**Note:** Click [here](#) to download the full example code or to run this example in your browser via Binder

#### 6.30.1 FeatureHasher and DictVectorizer Comparison

Compares FeatureHasher and DictVectorizer by using both to vectorize text documents.

The example demonstrates syntax and speed only; it doesn’t actually do anything useful with the extracted vectors. See the example scripts `{document_classification_20newsgroups,clustering}.py` for actual learning on text documents.

A discrepancy between the number of terms reported for DictVectorizer and for FeatureHasher is to be expected due to hash collisions.

**Out:**

```
Usage: /home/circleci/project/examples/text/plot_hashing_vs_dict_vectorizer.py [n_features_for_hashing]
    The default number of features is 2**18.

6.30.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- TfidfVectorizer uses an in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.
- HashingVectorizer hashes word occurrences to a fixed dimensional space, possibly with collisions. The word
count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

HashingVectorizer does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a TfidfTransformer instance.

Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the “ground truth” provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called “Concentration of Measure” or “Curse of Dimensionality” for high dimensional datasets such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

Out:

Usage: plot_document_clustering.py [options]

Options:
  -h, --help            show this help message and exit
  --lsa=N_COMPONENTS    Preprocess documents with latent semantic analysis.
  --no-minibatch       Use ordinary k-means algorithm (in batch mode).
  --no-idf             Disable Inverse Document Frequency feature weighting.
  --use-hashing        Use a hashing feature vectorizer
  --n-features=N_FEATURES  Maximum number of features (dimensions) to extract
                           from text.
  --verbose            Print progress reports inside k-means algorithm.

### 6.30.3 Classification of text documents using sparse features

This is an example showing how scikit-learn can be used to classify documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features and demonstrates various classifiers that can efficiently handle sparse matrices.

The dataset used in this example is the 20 newsgroups dataset. It will be automatically downloaded, then cached.
from sklearn.ensemble import RandomForestClassifier
from sklearn.utils.extmath import density

print(__doc__)
op.print_help()
print()
Options:
-h, --help show this help message and exit
--report Print a detailed classification report.
--chi2_select=SELECT_CHI2
    Select some number of features using a chi-squared test
--confusion_matrix Print the confusion matrix.
--top10 Print ten most discriminative terms per class for every classifier.
--all_categories Whether to use all categories or not.
--use_hashing Use a hashing vectorizer.
--n_features=N_FEATURES
    n_features when using the hashing vectorizer.
--filtered Remove newsgroup information that is easily overfit:
    headers, signatures, and quoting.

Load data from the training set

Let’s load data from the newsgroups dataset which comprises around 18000 newsgroups posts on 20 topics split in two subsets: one for training (or development) and the other one for testing (or for performance evaluation).

```python
if opts.all_categories:
    categories = None
else:
    categories = [
        'alt.atheism',
        'talk.religion.misc',
        'comp.graphics',
        'sci.space',
    ]

if opts.filtered:
    remove = ('headers', 'footers', 'quotes')
else:
    remove = ()

print("Loading 20 newsgroups dataset for categories:")
print(categories if categories else "all")

data_train = fetch_20newsgroups(subset='train', categories=categories,
                                shuffle=True, random_state=42,
                                remove=remove)

data_test = fetch_20newsgroups(subset='test', categories=categories,
                                shuffle=True, random_state=42,
                                remove=remove)

print('data loaded')

# order of labels in `target_names` can be different from `categories`
target_names = data_train.target_names

def size_mb(docs):
    return sum(len(s.encode('utf-8')) for s in docs) / 1e6
```

(continues on next page)

**sklearn.base.BaseEstimator**

class sklearn.base.BaseEstimator

    Base class for all estimators in scikit-learn

**Notes**

All estimators should specify all the parameters that can be set at the class level in their __init__ as explicit keyword arguments (no *args or **kwargs).

**Methods**

- get_params(self[, deep])
  - Get parameters for this estimator.
- set_params(self, **params)
  - Set the parameters of this estimator.
__init__(self, /, *args, **kwargs)
    Initialize self. See help(type(self)) for accurate signature.

get_params (self, deep=True)
    Get parameters for this estimator.

    Parameters
    ----------
    deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns
    -------
    params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
    Set the parameters of this estimator.

    The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

    Parameters
    ----------
    **params [dict] Estimator parameters.

    Returns
    -------
    self [object] Estimator instance.

Examples using sklearn.base.BaseEstimator

• Approximate nearest neighbors in TSNE

sklearn.base.BiclusterMixin

class sklearn.base.BiclusterMixin
    Mixin class for all bicluster estimators in scikit-learn

    Attributes
    ---------
    biclusters_ Convenient way to get row and column indicators together.

    Methods
    --------
    get_indices(self, i) Row and column indices of the i’th bicluster.
    get_shape(self, i) Shape of the i’th bicluster.
    get_submatrix(self, i, data) Return the submatrix corresponding to bicluster i.

__init__(self, /, *args, **kwargs)
    Initialize self. See help(type(self)) for accurate signature.

property biclusters_
    Convenient way to get row and column indicators together.

    Returns the rows_ and columns_ members.

get_indices (self, i)
Row and column indices of the i’th bicluster.
Only works if `rows_` and `columns_` attributes exist.

**Parameters**

- `i` [int] The index of the cluster.

**Returns**

- `row_ind` [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
- `col_ind` [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

**get_shape** *(self, i)*

Shape of the i’th bicluster.

**Parameters**

- `i` [int] The index of the cluster.

**Returns**

- `shape` [(int, int)] Number of rows and columns (resp.) in the bicluster.

**get_submatrix** *(self, i, data)*

Return the submatrix corresponding to bicluster i.

**Parameters**

- `i` [int] The index of the cluster.
- `data` [array] The data.

**Returns**

- `submatrix` [array] The submatrix corresponding to bicluster i.

**Notes**

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

---

**sklearn.base.ClassifierMixin**

**class sklearn.base.ClassifierMixin**

Mixin class for all classifiers in scikit-learn.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>score</code></td>
<td>Return the mean accuracy on the given test data and labels.</td>
</tr>
<tr>
<td><code>__init__</code></td>
<td>Initialize self. See help(type(self)) for accurate signature.</td>
</tr>
<tr>
<td><code>score</code></td>
<td>Return the mean accuracy on the given test data and labels.</td>
</tr>
</tbody>
</table>

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**
- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**sklearn.base.ClusterMixin**

class sklearn.base.ClusterMixin
   Mixin class for all cluster estimators in scikit-learn.

**Methods**

```
fit_predict(self, X[, y]) Perform clustering on X and returns cluster labels.
```

```
__init__(self, /, *args, **kwargs)
   Initialize self. See help(type(self)) for accurate signature.
```

```
fit_predict(self, X, y=None)
   Perform clustering on X and returns cluster labels.

   Parameters
   ----------
   X [ndarray, shape (n_samples, n_features)] Input data.
   y [Ignored] Not used, present for API consistency by convention.

   Returns
   -------
   labels [ndarray, shape (n_samples,)] Cluster labels.
```

**sklearn.base.DensityMixin**

class sklearn.base.DensityMixin
   Mixin class for all density estimators in scikit-learn.

**Methods**

```
score(self, X[, y]) Return the score of the model on the data X
```

```
__init__(self, /, *args, **kwargs)
   Initialize self. See help(type(self)) for accurate signature.
```

```
score(self, X, y=None)
   Return the score of the model on the data X
```

   Parameters
X [array-like of shape (n_samples, n_features)]

Returns
score [float]

sklearn.base.RegressorMixin

class sklearn.base.RegressorMixin
Mixin class for all regression estimators in scikit-learn.

Methods

score(self, X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.

__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

score (self, X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares ($\sum(y_true - y_pred)^2$) and $v$ is the total sum of squares ($\sum(y_true - y_true.mean())^2$). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

sklearn.base.TransformerMixin

class sklearn.base.TransformerMixin
Mixin class for all transformers in scikit-learn.
Methods

```
**fit_transform**(self, X[, y])
Fit to data, then transform it.

```  

```
__init__**(self, */*args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

```  

```
**fit_transform**(self, X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.
**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

Examples using sklearn.base.TransformerMixin

- Approximate nearest neighbors in TSNE

7.1.2 Functions

```
base.clone(estimator[, safe]) Constructs a new estimator with the same parameters.

base.is_classifier(estimator) Return True if the given estimator is (probably) a classifier.

base.is_regressor(estimator) Return True if the given estimator is (probably) a regressor.

config_context(**new_config) Context manager for global scikit-learn configuration

get_config() Retrieve current values for configuration set by set_config

set_config([assume_finite, working_memory, . . .]) Set global scikit-learn configuration

show_versions() Print useful debugging information

sklearn.base.clone

sklearn.base.clone(estimator, safe=True)
Constructs a new estimator with the same parameters.
Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fit on any data.

Parameters

estimator [estimator object, or list, tuple or set of objects] The estimator or group of estimators to be cloned

safe [boolean, optional] If safe is false, clone will fall back to a deep copy on objects that are not estimators.
**sklearn.base.is_classifier**

`sklearn.base.is_classifier(estimator)`

Return True if the given estimator is (probably) a classifier.

**Parameters**

- `estimator` [object] Estimator object to test.

**Returns**

- `out` [bool] True if estimator is a classifier and False otherwise.

**sklearn.base.is_regressor**

`sklearn.base.is_regressor(estimator)`

Return True if the given estimator is (probably) a regressor.

**Parameters**

- `estimator` [object] Estimator object to test.

**Returns**

- `out` [bool] True if estimator is a regressor and False otherwise.

**sklearn.config_context**

`sklearn.config_context(**new_config)`

Context manager for global scikit-learn configuration

**Parameters**

- `assume_finite` [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.
- `working_memory` [int, optional] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.
- `print_changed_only` [bool, optional] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print ‘SVC()’ while the default behaviour would be to print ‘SVC(C=1.0, cache_size=200, . . . )’ with all the non-changed parameters.

**See also:**

- `set_config` Set global scikit-learn configuration
- `get_config` Retrieve current values of the global configuration

**Notes**

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.
Examples

```python
>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...     assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...     with sklearn.config_context(assume_finite=False):
...         assert_all_finite([float('nan')])
Traceback (most recent call last):
...     ValueError: Input contains NaN, ...
```

**sklearn.get_config**

`sklearn.get_config()`  
Retrieve current values for configuration set by `set_config`  

**Returns**

`config` [dict] Keys are parameter names that can be passed to `set_config`.  

**See also:**

* `config_context` Context manager for global scikit-learn configuration  
* `set_config` Set global scikit-learn configuration

**sklearn.set_config**

`sklearn.set_config(assume_finite=None, working_memory=None, print_changed_only=None)`  
Set global scikit-learn configuration  

New in version 0.19.  

**Parameters**

* `assume_finite` [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.  
  
  New in version 0.19.  

* `working_memory` [int, optional] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.  
  
  New in version 0.20.  

* `print_changed_only` [bool, optional] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print ‘SVC()’ while the default behaviour would be to print ‘SVC(C=1.0, cache_size=200, . . . )’ with all the non-changed parameters.  
  
  New in version 0.21.  

**See also:**
config_context  Context manager for global scikit-learn configuration
get_config  Retrieve current values of the global configuration

Examples using sklearn.set_config

- Compact estimator representations

sklearn.show_versions

sklearn.show_versions()
Paren useful debugging information

7.2 sklearn.calibration: Probability Calibration

Calibration of predicted probabilities.
User guide: See the Probability calibration section for further details.

calibration.CalibratedClassifierCV([...]) Probability calibration with isotonic regression or sigmoid.

7.2.1 sklearn.calibration.CalibratedClassifierCV

class sklearn.calibration.CalibratedClassifierCV (base_estimator=None, method='sigmoid', cv=None)

Probability calibration with isotonic regression or sigmoid.
See glossary entry for cross-validation estimator.

With this class, the base_estimator is fit on the train set of the cross-validation generator and the test set is used for calibration. The probabilities for each of the folds are then averaged for prediction. In case that cv="prefit" is passed to __init__, it is assumed that base_estimator has been fitted already and all data is used for calibration. Note that data for fitting the classifier and for calibrating it must be disjoint.

Read more in the User Guide.

Parameters

- base_estimator  [instance BaseEstimator] The classifier whose output decision function needs to be calibrated to offer more accurate predict_proba outputs. If cv=prefit, the classifier must have been fit already on data.

- method  ['sigmoid' or 'isotonic'] The method to use for calibration. Can be ‘sigmoid’ which corresponds to Platt’s method or ‘isotonic’ which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples (<<1000) since it tends to overfit. Use sigmoids (Platt’s calibration) in this case.

- cv  [integer, cross-validation generator, iterable or "prefit", optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - integer, to specify the number of folds.
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if y is binary or multiclass, sklearn.model_selection.StratifiedKFold is used. If y is neither binary nor multiclass, sklearn.model_selection.KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

If “prefit” is passed, it is assumed that base_estimator has been fitted already and all data is used for calibration.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

Attributes

classes_ [array, shape (n_classes)] The class labels.

calibrated_classifiers_ [list (len() equal to cv or 1 if cv == “prefit”)] The list of calibrated classifiers, one for each crossvalidation fold, which has been fitted on all but the validation fold and calibrated on the validation fold.

References

[R57cf438d7060-1], [R57cf438d7060-2], [R57cf438d7060-3], [R57cf438d7060-4]

Methods

fit(self, X, y[, sample_weight]) Fit the calibrated model

generate_params(self[, deep]) Get parameters for this estimator.
predict(self, X) Predict the target of new samples.
predict_proba(self, X) Posterior probabilities of classification

score(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.

set_params(self, **params) Set the parameters of this estimator.

__init__ (self, base_estimator=None, method='sigmoid', cv=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y, sample_weight=None)
Fit the calibrated model

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

y [array-like, shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.

Returns

generate_params (self, deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**predict** *(self, X)*

Predict the target of new samples. Can be different from the prediction of the uncalibrated classifier.

**Parameters**

X [array-like, shape (n_samples, n_features)] The samples.

**Returns**

C [array, shape (n_samples,)] The predicted class.

**predict_proba** *(self, X)*

Posterior probabilities of classification

This function returns posterior probabilities of classification according to each class on an array of test vectors X.

**Parameters**

X [array-like, shape (n_samples, n_features)] The samples.

**Returns**

C [array, shape (n_samples, n_classes)] The predicted probas.

**score** *(self, X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

7.2. sklearn.calibration: Probability Calibration

1565
Examples using `sklearn.calibration.CalibratedClassifierCV`

- Probability Calibration curves
- Probability calibration of classifiers
- Probability Calibration for 3-class classification

```python
from sklearn.calibration import calibration_curve

calibration_curve(y_true, y_prob)
```

Compute true and predicted probabilities for a calibration curve.

The method assumes the inputs come from a binary classifier.

Calibration curves may also be referred to as reliability diagrams.

Read more in the *User Guide*.

**Parameters**

- `y_true` [array, shape (n_samples,)] True targets.
- `y_prob` [array, shape (n_samples,)] Probabilities of the positive class.
- `normalize` [bool, optional, default=False] Whether `y_prob` needs to be normalized into the bin [0, 1], i.e. is not a proper probability. If True, the smallest value in `y_prob` is mapped onto 0 and the largest one onto 1.
- `n_bins` [int] Number of bins. A bigger number requires more data. Bins with no data points (i.e. without corresponding values in `y_prob`) will not be returned, thus there may be fewer than `n_bins` in the return value.
- `strategy` [‘uniform’, ‘quantile’], (default=’uniform’) Strategy used to define the widths of the bins.
  - uniform All bins have identical widths.
  - quantile All bins have the same number of points.

**Returns**

- `prob_true` [array, shape (n_bins,) or smaller] The true probability in each bin (fraction of positives).
- `prob_pred` [array, shape (n_bins,) or smaller] The mean predicted probability in each bin.

- Comparison of Calibration of Classifiers
- Probability Calibration curves

7.3 sklearn.cluster: Clustering

The sklearn.cluster module gathers popular unsupervised clustering algorithms.

User guide: See the Clustering and Biclustering sections for further details.

7.3.1 Classes

```python
class sklearn.cluster.AffinityPropagation(  
    damping=0.5,  
    max_iter=200,  
    convergence_iter=15,  
    copy=True,  
    preference=None,  
    affinity='euclidean',  
    verbose=False)  
```

Perform Affinity Propagation Clustering of data.

Read more in the User Guide.

Parameters

- **damping** [float, default=0.5] Damping factor (between 0.5 and 1) is the extent to which the current value is maintained relative to incoming values (weighted 1 - damping). This in order to avoid numerical oscillations when updating these values (messages).
- **max_iter** [int, default=200] Maximum number of iterations.
- **convergence_iter** [int, default=15] Number of iterations with no change in the number of estimated clusters that stops the convergence.
copy [bool, default=True] Make a copy of input data.

preference [array-like of shape (n_samples,) or float, default=None] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.

affinity [{'euclidean', 'precomputed'}, default='euclidean'] Which affinity to use. At the moment 'precomputed' and euclidean are supported. 'euclidean' uses the negative squared euclidean distance between points.

verbose [bool, default=False] Whether to be verbose.

Attributes

cluster_centers_indices_ [ndarray of shape (n_clusters,)] Indices of cluster centers

cluster_centers_ [ndarray of shape (n_clusters, n_features)] Cluster centers (if affinity != precomputed).

labels_ [ndarray of shape (n_samples,)] Labels of each point

affinity_matrix_ [ndarray of shape (n_samples, n_samples)] Stores the affinity matrix used in fit.

n_iter_ [int] Number of iterations taken to converge.

Notes

For an example, see examples/cluster/plot_affinity_propagation.py.

The algorithmic complexity of affinity propagation is quadratic in the number of points.

When fit does not converge, cluster_centers_ becomes an empty array and all training samples will be labelled as -1. In addition, predict will then label every sample as -1.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, fit will result in a single cluster center and label 0 for every sample. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

References

Examples

```python
>>> from sklearn.cluster import AffinityPropagation
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0], ...
...               [4, 2], [4, 4], [4, 0]])
>>> clustering = AffinityPropagation().fit(X)
>>> clustering
AffinityPropagation()
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
>>> clustering.predict([[0, 0], [4, 4]])
array([0, 1])
```

__init__ (self, damping=0.5, max_iter=200, convergence_iter=15, copy=True, preference=None, affinity='euclidean', verbose=False)

Initialize self. See help(type(self)) for accurate signature.

**fit** (self, X, y=None)

Fit the clustering from features, or affinity matrix.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse feature matrix is provided, it will be converted into a sparse csr_matrix.

- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **self**

**fit_predict** (self, X, y=None)

Fit the clustering from features or affinity matrix, and return cluster labels.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse feature matrix is provided, it will be converted into a sparse csr_matrix.

- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **labels** [ndarray, shape (n_samples,)] Cluster labels.

**get_params** (self, deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

7.3. sklearn.cluster: Clustering
params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict the closest cluster each sample in X belongs to.

Parameters
X [array-like or sparse matrix, shape (n_samples, n_features)] New data to predict. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns
labels [ndarray, shape (n_samples,)] Cluster labels.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

Examples using sklearn.cluster.AffinityPropagation

- Demo of affinity propagation clustering algorithm
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.AggglomerativeClustering

class sklearn.cluster.AgglomerativeClustering (n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', distance_threshold=None)

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Parameters

n_clusters [int or None, default=2] The number of clusters to find. It must be None if distance_threshold is not None.

affinity [str or callable, default='euclidean'] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or “precomputed”. If linkage is “ward”, only “euclidean” is accepted. If “precomputed”, a distance matrix (instead of a similarity matrix) is needed as input for the fit method.

memory [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.
connectivity [array-like or callable, default=None] Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

compute_full_tree [‘auto’ or bool, default=’auto’] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be True if distance_threshold is not None. By default compute_full_tree is “auto”, which is equivalent to True when distance_threshold is not None or that n_clusters is inferior to the maximum between 100 or 0.02 * n_samples. Otherwise, “auto” is equivalent to False.

linkage [{“ward”, “complete”, “average”, “single”}, default=“ward”] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of cluster that minimize this criterion.
• ward minimizes the variance of the clusters being merged.
• average uses the average of the distances of each observation of the two sets.
• complete or maximum linkage uses the maximum distances between all observations of the two sets.
• single uses the minimum of the distances between all observations of the two sets.

distance_threshold [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not None, n_clusters must be None and compute_full_tree must be True.

New in version 0.21.

Attributes

  n_clusters_ [int] The number of clusters found by the algorithm. If distance_threshold=None, it will be equal to the given n_clusters.

  labels_ [ndarray of shape (n_samples)] cluster labels for each point

  n_leaves_ [int] Number of leaves in the hierarchical tree.

  n_connected_components_ [int] The estimated number of connected components in the graph.

  children_ [array-like of shape (n_samples-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children[i][1 – n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i

Examples

```python
>>> from sklearn.cluster import AgglomerativeClustering
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0], ...
                [4, 2], [4, 4], [4, 0]])
>>> clustering = AgglomerativeClustering().fit(X)
>>> clustering
AgglomerativeClustering()
```

__init__(self, n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', distance_threshold=None)

Initialize self. See help(type(self)) for accurate signature.

`fit (self, X, y=None)`
Fit the hierarchical clustering from features, or distance matrix.

Parameters

- **X** [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `affinity='precomputed'`.
- **y** [Ignored] Not used, present here for API consistency by convention.

Returns

- **self**

`fit_predict (self, X, y=None)`
Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

Parameters

- **X** [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `affinity='precomputed'`.
- **y** [Ignored] Not used, present here for API consistency by convention.

Returns

- **labels** [ndarray, shape (n_samples,)] Cluster labels.

`get_params (self, deep=True)`
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

`set_params (self, **params)`
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**sklearn.cluster.Birch**

class sklearn.cluster.Birch (threshold=0.5, branching_factor=50, n_clusters=3, compute_labels=True, copy=True)

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to MiniBatchKMeans. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as AgglomerativeClustering.

Read more in the User Guide.

New in version 0.16.

**Parameters**

threshold [float, default=0.5] The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.

branching_factor [int, default=50] Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the branching_factor then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

n_clusters [int, instance of sklearn.cluster model, default=3] Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.

- None: the final clustering step is not performed and the subclusters are returned as they are.
• **sklearn.cluster** Estimator: If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest sub-cluster.

• **int**: the model fit is **AgglomerativeClustering** with **n_clusters** set to be equal to the int.

**compute_labels** [bool, default=True] Whether or not to compute labels for each fit.

**copy** [bool, default=True] Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

**Attributes**

- **root_** [CFNode] Root of the CFTree.
- **dummy_leaf_** [CFNode] Start pointer to all the leaves.
- **subcluster_centers_** [ndarray] Centroids of all subclusters read directly from the leaves.
- **subcluster_labels_** [ndarray] Labels assigned to the centroids of the subclusters after they are clustered globally.
- **labels_** [ndarray, shape (n_samples,)] Array of labels assigned to the input data. If partial_fit is used instead of fit, they are assigned to the last batch of data.

**See also:**

**MiniBatchKMeans** Alternative implementation that does incremental updates of the centers’ positions using mini-batches.

**Notes**

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

array([0, 0, 0, 1, 1, 1])
```

**__init__**(self, `threshold=0.5, branching_factor=50, n_clusters=3, compute_labels=True, copy=True)

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, `X[, y]`) Build a CF Tree for the input data.

**Parameters**

- `X` ([array-like, sparse matrix], shape (n_samples, n_features)) Input data.
- `y` [Ignored] Not used, present here for API consistency by convention.

**Returns**

- `self` Fitted estimator.

**fit_predict**(self, `X[, y]`) Perform clustering on X and returns cluster labels.

**Parameters**

- `X` [ndarray, shape (n_samples, n_features)] Input data.
- `y` [Ignored] Not used, present for API consistency by convention.

**Returns**

- `labels` [ndarray, shape (n_samples,)] Cluster labels.

**fit_transform**(self, `X[, y=None, **fit_params]`) Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- `X` [numpay array of shape [n_samples, n_features]] Training set.
- `y` [numpay array of shape [n_samples]] Target values.
- `**fit_params` [dict] Additional fit parameters.

**Returns**

- `X_new` [numpay array of shape [n_samples, n_features_new]] Transformed array.
**get_params** *(self, deep=True)*
Get parameters for this estimator.

Parameters

*deep [bool, default=True]* If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

*params [mapping of string to any]* Parameter names mapped to their values.

**partial_fit** *(self, X=None, y=None)*
Online learning. Prevents rebuilding of CFTree from scratch.

Parameters

*X [array-like, sparse matrix], shape (n_samples, n_features), None]* Input data. If X is not provided, only the global clustering step is done.

*y [Ignored]* Not used, present here for API consistency by convention.

Returns

*self Fitted estimator.*

**predict** *(self, X)*
Predict data using the centroids of subclusters.

Avoid computation of the row norms of X.

Parameters

*X [array-like, sparse matrix], shape (n_samples, n_features)]* Input data.

Returns

*labels [ndarray, shape(n_samples)]* Labelled data.

**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict]* Estimator parameters.

Returns

*self [object]* Estimator instance.

**transform** *(self, X)*
Transform X into subcluster centroids dimension.

Each dimension represents the distance from the sample point to each cluster centroid.

Parameters

*X [array-like, sparse matrix], shape (n_samples, n_features)]* Input data.

Returns

*X_trans [array-like, sparse matrix], shape (n_samples, n_clusters)]* Transformed data.
Examples using `sklearn.cluster.Birch`

- Compare BIRCH and MiniBatchKMeans
- Comparing different clustering algorithms on toy datasets

`sklearn.cluster.DBSCAN`

```python
class sklearn.cluster.DBSCAN(eps=0.5, min_samples=5, metric='euclidean', metric_params=None, algorithm='auto', leaf_size=30, p=None, n_jobs=None)
```

Perform DBSCAN clustering from vector array or distance matrix.

DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.

Read more in the User Guide.

**Parameters**

- **eps** [float, default=0.5] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

- **min_samples** [int, default=5] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

- **metric** [string, or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a `Glossary`, in which case only “nonzero” elements may be considered neighbors for DBSCAN.

  New in version 0.17: metric `precomputed` to accept precomputed sparse matrix.

- **metric_params** [dict, default=None] Additional keyword arguments for the metric function.

  New in version 0.19.

- **algorithm** [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

- **leaf_size** [int, default=30] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **p** [float, default=None] The power of the Minkowski metric to be used to calculate distance between points.

- **n_jobs** [int or None, default=None] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

**Attributes**

- **core_sample_indices_** [array, shape = [n_core_samples]] Indices of core samples.

- **components_** [array, shape = [n_core_samples, n_features]] Copy of each core sample found by training.
labels_  [array, shape = [n_samples]] Cluster labels for each point in the dataset given to fit().
    Noisy samples are given the label -1.

See also:

**OPTICS** A similar clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see `examples/cluster/plot_dbscan.py`.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to
O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n).
It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the
algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks
using `NearestNeighbors.radius_neighbors_graph` with mode='distance', then using
metric='precomputed' here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use
sample_weight instead.

`cluster.OPTICS` provides a similar clustering with lower memory usage.

get_params (self[, deep])  Get parameters for this estimator.

set_params (self, **params)  Set the parameters of this estimator.

__init__ (self, eps=0.5, min_samples=5, metric='euclidean', metric_params=None, algorithm='auto', leaf_size=30, p=None, n_jobs=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None, sample_weight=None)
Perform DBSCAN clustering from features, or distance matrix.

Parameters
X  [array-like or sparse matrix, shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if metric='precomputed'. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.
sample_weight  [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.
y  [Ignored] Not used, present here for API consistency by convention.

Returns
self

fit_predict (self, X, y=None, sample_weight=None)
Perform DBSCAN clustering from features or distance matrix, and return cluster labels.

Parameters
X  [array-like or sparse matrix, shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if metric='precomputed'. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.
sample_weight  [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.
y  [Ignored] Not used, present here for API consistency by convention.

Returns
labels  [ndarray, shape (n_samples,)] Cluster labels. Noisy samples are given the label -1.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params  [mapping of string to any] Parameter names mapped to their values.
set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sklearn.cluster.FeatureAgglomeration

class sklearn.cluster.FeatureAgglomeration (n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func=<function mean>, distance_threshold=None)

Agglomerate features.

Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the User Guide.

Parameters

n_clusters [int, default=2] The number of clusters to find. It must be None if distance_threshold is not None.

affinity [str or callable, default='euclidean'] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or ‘precomputed’. If linkage is “ward”, only “euclidean” is accepted.

memory [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

connectivity [array-like or callable, default=None] Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

compute_full_tree [‘auto’ or bool, optional, default=’auto’] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be
True if distance_threshold is not None. By default compute_full_tree is
"auto", which is equivalent to True when distance_threshold is not None or that
n_clusters is inferior to the maximum between 100 or 0.02 * n_samples. Other-
wise, "auto" is equivalent to False.

linkage [{"ward", ‘complete’, ‘average’, ‘single’}, default='ward'] Which linkage criterion to
use. The linkage criterion determines which distance to use between sets of features. The
algorithm will merge the pairs of cluster that minimize this criterion.

• ward minimizes the variance of the clusters being merged.
• average uses the average of the distances of each feature of the two sets.
• complete or maximum linkage uses the maximum distances between all features of the
two sets.
• single uses the minimum of the distances between all observations of the two sets.

pooling_func [callable, default=np.mean] This combines the values of agglomerated features
into a single value, and should accept an array of shape [M, N] and the keyword argument
axis=1, and reduce it to an array of size [M].

distance_threshold [float, default=None] The linkage distance threshold above which,
clusters will not be merged. If not None, n_clusters must be None and
compute_full_tree must be True.

New in version 0.21.

Attributes

n_clusters_ [int] The number of clusters found by the algorithm. If
distance_threshold=None, it will be equal to the given n_clusters.

labels_ [array-like of (n_features,)] cluster labels for each feature.

n_leaves_ [int] Number of leaves in the hierarchical tree.

n_connected_components_ [int] The estimated number of connected components in the graph.

children_ [array-like of shape (n_nodes-1, 2)] The children of each non-leaf node. Values
less than n_features correspond to leaves of the tree which are the original samples. A
node i greater than or equal to n_features is a non-leaf node and has children
children_[i - n_features]. Alternatively at the i-th iteration, children[i][0] and
children[i][1] are merged to form node n_features + i

distances_ [array-like of shape (n_nodes-1,)] Distances between nodes in the corresponding
place in children_. Only computed if distance_threshold is not None.

Examples

```python
>>> import numpy as np
>>> from sklearn import datasets, cluster
>>> digits = datasets.load_digits()
>>> images = digits.images
>>> X = np.reshape(images, (len(images), -1))
>>> agglo = cluster.FeatureAgglomeration(n_clusters=32)
>>> agglo.fit(X)
FeatureAgglomeration(n_clusters=32)
>>> X_reduced = agglo.transform(X)
>>> X_reduced.shape
(1797, 32)
```

__init__(self, n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func=<function mean at 0x7f5106354440>, distance_threshold=None)
```

Initialize self. See help(type(self)) for accurate signature.

```
fit (self, X, y=None, **params)
```

Fit the hierarchical clustering on the data

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data
- **y** [Ignored]

**Returns**

- **self**

```
property fit_predict
```

Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

**Parameters**

- **X** [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `affinity='precomputed'`.
- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **labels** [ndarray, shape (n_samples,)] Cluster labels.

```
fit_transform (self, X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

```
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, Xred)
Inverse the transformation. Return a vector of size nb_features with the values of Xred assigned to each
group of features

Parameters

Xred [array-like of shape (n_samples, n_clusters) or (n_clusters,)] The values to be assigned
to each cluster of samples

Returns

X [array, shape=[n_samples, n_features] or [n_features]] A vector of size n_samples with
the values of Xred assigned to each of the cluster of samples.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Transform a new matrix using the built clustering

Parameters

X [array-like of shape (n_samples, n_features) or (n_samples,)] A M by N array of M ob-
servations in N dimensions or a length M array of M one-dimensional observations.

Returns

Y [array, shape = [n_samples, n_clusters] or [n_clusters]] The pooled values for each feature
cluster.

Examples using sklearn.cluster.FeatureAgglomeration

- Feature agglomeration
- Feature agglomeration vs. univariate selection

sklearn.cluster.KMeans

class sklearn.cluster.KMeans (n_clusters=8, init='k-means++', n_init=10, max_iter=300,
tol=0.0001, precompute_distances='auto', verbose=0, random_state=None, copy_x=True, n_jobs=None, algorithm='auto')

K-Means clustering.
Parameters

- **n_clusters** [int, default=8] The number of clusters to form as well as the number of centroids to generate.
- **init** [{‘k-means++’, ‘random’} or ndarray of shape (n_clusters, n_features), default=’k-means++’] Method for initialization, defaults to ‘k-means++’:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose k observations (rows) at random from data for the initial centroids.
  If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
- **n_init** [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- **max_iter** [int, default=300] Maximum number of iterations of the k-means algorithm for a single run.
- **tol** [float, default=1e-4] Relative tolerance with regards to inertia to declare convergence.
- **precompute_distances** ['auto' or bool, default='auto'] Precompute distances (faster but takes more memory).
  - ‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
  - True : always precompute distances.
  - False : never precompute distances.
- **verbose** [int, default=0] Verbosity mode.
- **random_state** [int, RandomState instance, default=None] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See Glossary.
- **copy_X** [bool, default=True] When pre-computing distances it is more numerically accurate to center the data first. If copy_X is True (default), then the original data is not modified, ensuring X is C-contiguous. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean, in this case it will also not ensure that data is C-contiguous which may cause a significant slowdown.
- **n_jobs** [int, default=None] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.
  - None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **algorithm** [{‘auto’, ‘full’, ‘elkan’}, default=’auto’] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. “auto” chooses “elkan” for dense data and “full” for sparse data.

Attributes
cluster_centers_  [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers. If the algorithm stops before fully converging (see tol and max_iter), these will not be consistent with labels_.

labels_  [ndarray of shape (n_samples,)] Labels of each point

inertia_  [float] Sum of squared distances of samples to their closest cluster center.

n_iter_  [int] Number of iterations run.

See also:

MiniBatchKMeans  Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say n_samples > 10k) MiniBatchKMeans is probably much faster than the default batch implementation.

Notes

The k-means problem is solved using either Lloyd’s or Elkan’s algorithm.

The average complexity is given by O(k n T), were n is the number of samples and T is the number of iteration.

The worst case complexity is given by O(n^(k+2/p)) with n = n_samples, p = n_features. (D. Arthur and S. Vassilvitskii, ‘How slow is the k-means method?’ SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That’s why it can be useful to restart it several times.

If the algorithm stops before fully converging (because of tol or max_iter), labels_ and cluster_centers_ will not be consistent, i.e. the cluster_centers_ will not be the means of the points in each cluster. Also, the estimator will reassign labels_ after the last iteration to make labels_ consistent with predict on the training set.

Examples

```python
>>> from sklearn.cluster import KMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0], ...
[10, 2], [10, 4], [10, 0]])
>>> kmeans = KMeans(n_clusters=2, random_state=0).fit(X)
>>> kmeans.labels_.
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> kmeans.predict([0, 0], [12, 3])
array([1, 0], dtype=int32)
>>> kmeans.cluster_centers_.
array([[10., 2.],
[ 1., 2.]])
```

Methods

| `fit(self, X[, y, sample_weight])` | Compute k-means clustering. |
| `fit_predict(self, X[, y, sample_weight])` | Compute cluster centers and predict cluster index for each sample. |

__init__ (self, n_clusters=8, init='k-means++', n_init=10, max_iter=300, tol=0.0001, precompute_distances='auto', verbose=0, random_state=None, copy_x=True, n_jobs=None, algorithm='auto')

Initialize self. See help(type(self)) for accurate signature.

**fit** (self, X, y=None, sample_weight=None)
Compute k-means clustering.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

- **y** [Ignored] Not used, present here for API consistency by convention.

- **sample_weight** [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

**Returns**

- **self** Fitted estimator.

**fit_predict** (self, X, y=None, sample_weight=None)
Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

- **y** [Ignored] Not used, present here for API consistency by convention.

- **sample_weight** [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

**Returns**

- **labels** [array, shape [n_samples,]] Index of the cluster each sample belongs to.

**fit_transform** (self, X, y=None, sample_weight=None)
Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

- **y** [Ignored] Not used, present here for API consistency by convention.

- **sample_weight** [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).
Returns

X_new  [array, shape [n_samples, k]] X transformed in the new space.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

predict (self, X, sample_weight=None)
Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, cluster_centers_ is called the code book and each value returned by predict is the index of the closest code in the code book.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.

sample_weight  [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels  [array, shape [n_samples,]] Index of the cluster each sample belongs to.

score (self, X, y=None, sample_weight=None)
Opposite of the value of X on the K-means objective.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] New data.

y  [Ignored] Not used, present here for API consistency by convention.

sample_weight  [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

score  [float] Opposite of the value of X on the K-means objective.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

transform (self, X)
Transform X to a cluster-distance space.
In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by transform will typically be dense.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

**Returns**

- **X_new** [array, shape [n_samples, k]] X transformed in the new space.

### sklearn.cluster.MiniBatchKMeans

**class sklearn.cluster.MiniBatchKMeans**(n_clusters=8, init='k-means++', max_iter=100, batch_size=100, verbose=0, compute_labels=True, random_state=None, tol=0.0, max_no_improvement=10, init_size=None, n_init=3, reassignment_ratio=0.01)

Mini-Batch K-Means clustering.

**Parameters**

- **n_clusters** [int, default=8] The number of clusters to form as well as the number of centroids to generate.
- **init** [{‘k-means++’, ‘random’} or ndarray of shape (n_clusters, n_features), default=’k-means++’] Method for initialization
  - ‘k-means++’: selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose k observations (rows) at random from data for the initial centroids.
  - If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
- **max_iter** [int, default=100] Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.
- **batch_size** [int, default=100] Size of the mini batches.
verbose [int, default=0] Verbosity mode.

compute_labels [bool, default=True] Compute label assignment and inertia for the complete
dataset once the minibatch optimization has converged in fit.

random_state [int, RandomState instance, default=None] Determines random number generation
for centroid initialization and random reassignment. Use an int to make the randomness
deterministic. See Glossary.

tol [float, default=0.0] Control early stopping based on the relative center changes as measured
by a smoothed, variance-normalized of the mean center squared position changes. This
early stopping heuristics is closer to the one used for the batch variant of the algorithms but
induces a slight computational and memory overhead over the inertia heuristic.

To disable convergence detection based on normalized center change, set tol to 0.0 (default).

max_no_improvement [int, default=10] Control early stopping based on the consecutive num-
ber of mini batches that does not yield an improvement on the smoothed inertia.

To disable convergence detection based on inertia, set max_no_improvement to None.

init_size [int, default=None] Number of samples to randomly sample for speeding up the initial-
ization (sometimes at the expense of accuracy): the only algorithm is initialized by running
a batch KMeans on a random subset of the data. This needs to be larger than n_clusters.

If None, init_size = 3 * batch_size.

n_init [int, default=3] Number of random initializations that are tried. In contrast to KMeans,
the algorithm is only run once, using the best of the n_init initializations as measured by
inertia.

reassignment_ratio [float, default=0.01] Control the fraction of the maximum number of
counts for a center to be reassigned. A higher value means that low count centers are more
easily reassigned, which means that the model will take longer to converge, but should con-
verge in a better clustering.

Attributes

cluster_centers_ [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers

labels_ [int] Labels of each point (if compute_labels is set to True).

inertia_ [float] The value of the inertia criterion associated with the chosen partition (if com-
pute_labels is set to True). The inertia is defined as the sum of square distances of samples
to their nearest neighbor.

Examples
```python
>>> from sklearn.cluster import MiniBatchKMeans
>>> import numpy as np

>>> X = np.array([[1, 2], [1, 4], [1, 0],
    ...               [4, 2], [4, 0], [4, 4],
    ...               [4, 5], [0, 1], [2, 2],
    ...               [3, 2], [5, 5], [1, -1]])

>>> # manually fit on batches
>>> kmeans = MiniBatchKMeans(n_clusters=2,
    ...                           random_state=0,
    ...                           batch_size=6)

>>> kmeans = kmeans.partial_fit(X[0:6,:])

>>> kmeans = kmeans.partial_fit(X[6:12,:])

>>> kmeans.cluster_centers_
array([[2. , 1. ],
        [3.5, 4.5]])

>>> kmeans.predict([[0, 0], [4, 4]])
array([0, 1], dtype=int32)

>>> # fit on the whole data
>>> kmeans = MiniBatchKMeans(n_clusters=2,
    ...                           random_state=0,
    ...                           batch_size=6,
    ...                           max_iter=10).fit(X)

>>> kmeans.cluster_centers_
array([[3.95918367, 2.40816327],
        [1.12195122, 1.3902439]])

>>> kmeans.predict([[0, 0], [4, 4]])
array([1, 0], dtype=int32)
```

### __init__

```python
__init__(self, n_clusters=8, init='k-means++', max_iter=100, batch_size=100, verbose=0, compute_labels=True, random_state=None, tol=0.0, max_no_improvement=10, init_size=None, n_init=3, reassignment_ratio=0.01)
```

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X[, y=None, sample_weight=None])

Compute the centroids on X by chunking it into mini-batches.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Training instances to cluster.
It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

self

fit_predict (self, X, y=None, sample_weight=None)
Compute cluster centers and predict cluster index for each sample.
Convenience method; equivalent to calling fit(X) followed by predict(X).

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.
y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

fit_transform (self, X, y=None, sample_weight=None)
Compute clustering and transform X to cluster-distance space.
Equivalent to fit(X).transform(X), but more efficiently implemented.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.
y [Ignored] Not used, present here for API consistency by convention.

Returns

X_new [array, shape [n_samples, k]] X transformed in the new space.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y=None, sample_weight=None)
Update k means estimate on a single mini-batch X.

Parameters

X [array-like of shape (n_samples, n_features)] Coordinates of the data points to cluster. It must be noted that X will be copied if it is not C-contiguous.
y [Ignored] Not used, present here for API consistency by convention.

**sample_weight** [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

**Returns**

self

**predict**(self, X, sample_weight=None)

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, **cluster_centers** is called the code book and each value returned by **predict** is the index of the closest code in the code book.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) New data to predict.
- **sample_weight** [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

**Returns**

- **labels** [array, shape [n_samples,]] Index of the cluster each sample belongs to.

**score**(self, X, y=None, sample_weight=None)

Opposite of the value of X on the K-means objective.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) New data.
- **y** [Ignored] Not used, present here for API consistency by convention.
- **sample_weight** [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

**Returns**

- **score** [float] Opposite of the value of X on the K-means objective.

**set_params**(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform**(self, X)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by **transform** will typically be dense.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) New data to transform.

**Returns**
X_new [array, shape [n_samples, k]] X transformed in the new space.

Examples using sklearn.cluster.MiniBatchKMeans

sklearn.cluster.MeanShift

class sklearn.cluster.MeanShift (bandwidth=None, seeds=None, bin_seeding=False,
min_bin_freq=1, cluster_all=True, n_jobs=None, max_iter=300)

Mean shift clustering using a flat kernel.

Mean shift clustering aims to discover “blobs” in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the User Guide.

Parameters

bandwidth [float, optional] Bandwidth used in the RBF kernel.

If not given, the bandwidth is estimated using sklearn.cluster.estimate_bandwidth; see the documentation for that function for hints on scalability (see also the Notes, below).

seeds [array, shape=[n_samples, n_features], optional] Seeds used to initialize kernels. If not set, the seeds are calculated by clustering.get_bin_seeds with bandwidth as the grid size and default values for other parameters.

bin_seeding [boolean, optional] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. default value: False Ignored if seeds argument is not None.

min_bin_freq [int, optional] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds. If not defined, set to 1.

cluster_all [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.
**n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**max_iter** [int, default=300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

New in version 0.22.

**Attributes**

- **cluster_centers_** [array, [n_clusters, n_features]] Coordinates of cluster centers.
- **labels_** Labels of each point.
- **n_iter_** [int] Maximum number of iterations performed on each seed.

New in version 0.22.

**Notes**

**Scalability:**

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards \(O(T*n*log(n))\) in lower dimensions, with \(n\) the number of samples and \(T\) the number of points. In higher dimensions the complexity will tend towards \(O(T*n^2)\).

Scalability can be boosted by using fewer seeds, for example by using a higher value of min_bin_freq in the get_bin_seeds function.

Note that the estimate_bandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

**References**

**Examples**

```python
>>> from sklearn.cluster import MeanShift
>>> import numpy as np

>>> X = np.array([[1, 1], [2, 1], [1, 0],
                [4, 7], [3, 5], [3, 6]])

>>> clustering = MeanShift(bandwidth=2).fit(X)

>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])

>>> clustering.predict([[0, 0], [5, 5]])
array([1, 0])

>>> clustering
MeanShift(bandwidth=2)
```

- **`__init__`**
  
  Initialize self. See help(type(self)) for accurate signature.

- **`fit`**
  
  Perform clustering.

  Parameters
  
  X [array-like of shape (n_samples, n_features)] Samples to cluster.
  
  y [Ignored]

- **`fit_predict`**
  
  Perform clustering on X and returns cluster labels.

  Parameters
  
  X [ndarray, shape (n_samples, n_features)] Input data.
  
  y [Ignored] Not used, present for API consistency by convention.

  Returns
  
  labels [ndarray, shape (n_samples,)] Cluster labels.

- **`get_params`**
  
  Get parameters for this estimator.

  Parameters
  
  deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

  Returns
  
  params [mapping of string to any] Parameter names mapped to their values.

- **`predict`**
  
  Predict the closest cluster each sample in X belongs to.

  Parameters
  
  X [[array-like, sparse matrix], shape=[n_samples, n_features]] New data to predict.

  Returns
  
  labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

- **`set_params`**
  
  Set the parameters of this estimator.

  The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

  Parameters
**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.cluster.MeanShift

- Comparing different clustering algorithms on toy datasets

sklearn.cluster.OPTICS

class sklearn.cluster.OPTICS (min_samples=5, max_eps=inf, metric='minkowski', p=2, metric_params=None, cluster_method='xi', eps=None, xi=0.05, predecessor_correction=True, min_cluster_size=None, algorithm='auto', leaf_size=30, n_jobs=None)

Estimate clustering structure from vector array.

OPTICS (Ordering Points To Identify the Clustering Structure), closely related to DBSCAN, finds core sample of high density and expands clusters from them [R2c55e37003fe-1]. Unlike DBSCAN, keeps cluster hierarchy for a variable neighborhood radius. Better suited for usage on large datasets than the current sklearn implementation of DBSCAN.

Clusters are then extracted using a DBSCAN-like method (cluster_method = ‘dbscan’) or an automatic technique proposed in [R2c55e37003fe-1] (cluster_method = ‘xi’).

This implementation deviates from the original OPTICS by first performing k-nearest-neighborhood searches on all points to identify core sizes, then computing only the distances to unprocessed points when constructing the cluster order. Note that we do not employ a heap to manage the expansion candidates, so the time complexity will be $O(n^2)$.

Read more in the User Guide.

Parameters

- **min_samples** [int > 1 or float between 0 and 1 (default=5)] The number of samples in a neighborhood for a point to be considered as a core point. Also, up and down steep regions can’t have more then **min_samples** consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

- **max_eps** [float, optional (default=np.inf)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of np.inf will identify clusters across all scales; reducing **max_eps** will result in shorter run times.

- **metric** [str or callable, optional (default=’minkowski’)] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string. If metric is “precomputed”, X is assumed to be a distance matrix and must be square.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, optional (default=2)] Parameter for the Minkowski metric from sklearn.metrics.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, optional (default=None)] Additional keyword arguments for the metric function.

cluster_method [str, optional (default='xi')] The extraction method used to extract clusters using the calculated reachability and ordering. Possible values are “xi” and “dbscan”.

eps [float, optional (default=None)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. By default it assumes the same value as max_eps. Used only when cluster_method='dbscan'.

xi [float, between 0 and 1, optional (default=0.05)] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi.

predecessor_correction [bool, optional (default=True)] Correct clusters according to the predecessors calculated by OPTICS [R2c55e37003fe-2]. This parameter has minimal effect on most datasets. Used only when cluster_method='xi'.

min_cluster_size [int > 1 or float between 0 and 1 (default=None)] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If None, the value of min_samples is used instead. Used only when cluster_method='xi'.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, optional (default=30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

labels_ [array, shape (n_samples,)] Cluster labels for each point in the dataset given to fit(). Noisy samples and points which are not included in a leaf cluster of cluster_hierarchy_ are labeled as -1.
reachability_ [array, shape (n_samples,)] Reachability distances per sample, indexed by object order. Use clust.reachability_[clust.ordering_] to access in cluster order.

ordering_ [array, shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [array, shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never become core have a distance of inf. Use clust.core_distances_[clust.ordering_] to access in cluster order.

predecessor_ [array, shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

cluster_hierarchy_ [array, shape (n_clusters, 2)] The list of clusters in the form of [start, end] in each row, with all indices inclusive. The clusters are ordered according to (end, -start) (ascending) so that larger clusters encompassing smaller clusters come after those smaller ones. Since labels_ does not reflect the hierarchy, usually len(cluster_hierarchy_) > np.unique(optics.labels_). Please also note that these indices are of the ordering_, i.e. X[ordering_][start:end + 1] form a cluster. Only available when cluster_method='xi'.

See also:

DBSCAN A similar clustering for a specified neighborhood radius (eps). Our implementation is optimized for runtime.

Examples

```python
>>> from sklearn.cluster import OPTICS
>>> import numpy as np
>>> X = np.array([[1, 2], [2, 5], [3, 6],
... [8, 7], [8, 8], [7, 3]])
>>> clustering = OPTICS(min_samples=2).fit(X)
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
```

Methods

```python
fit(self, X[, y]) Perform OPTICS clustering.
fit_predict(self, X[, y]) Perform clustering on X and returns cluster labels.
get_params(self[, deep]) Get parameters for this estimator.
set_params(self, **params) Set the parameters of this estimator.
```
Extracts an ordered list of points and reachability distances, and performs initial clustering using $\text{max}_\text{eps}$ distance specified at OPTICS object instantiation.

**Parameters**

- **X** [array, shape (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'] A feature array, or array of distances between samples if metric='precomputed'.
- **y** [ignored] Ignored.

**Returns**

- **self** [instance of OPTICS] The instance.

**fit_predict**(self, X, y=None)
Perform clustering on X and returns cluster labels.

**Parameters**

- **X** [ndarray, shape (n_samples, n_features)] Input data.
- **y** [Ignored] Not used, present for API consistency by convention.

**Returns**

- **labels** [ndarray, shape (n_samples,)] Cluster labels.

**get_params**(self, deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params**(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**Examples using sklearn.cluster.OPTICS**

- Demo of OPTICS clustering algorithm
- Comparing different clustering algorithms on toy datasets
Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling `fit`, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distance $d(X, X)$:

$$\exp(-\gamma \times d(X, X)^2)$$

or a k-nearest neighbors connectivity matrix.

Alternatively, using `precomputed`, a user-provided affinity matrix can be used.

**Parameters**

- `n_clusters` [integer, optional] The dimension of the projection subspace.
- `eigen_solver` [None, ‘arpack’, ‘lobpcg’, or ‘amg’] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.
- `n_components` [integer, optional, default=n_clusters] Number of eigen vectors to use for the spectral embedding.
- `random_state` [int, RandomState instance or None (default)] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when `eigen_solver='amg'` and by the K-Means initialization. Use an int to make the randomness deterministic. See [Glossary](http://scikit-learn.org/stable/glossary.html).
- `n_init` [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- `gamma` [float, default=1.0] Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for `affinity='nearest_neighbors'`.
- `affinity` [string or callable, default='rbf']

**How to construct the affinity matrix.**

- ‘nearest_neighbors’ : construct the affinity matrix by computing a graph of nearest neighbors.
- ‘rbf’ : construct the affinity matrix using a radial basis function (RBF) kernel.
- ‘precomputed’ : interpret X as a precomputed affinity matrix.
• ‘precomputed_nearest_neighbors’ : interpret X as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the n_neighbors nearest neighbors.

• one of the kernels supported by pairwise_kernels.

Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.

n_neighbors [integer] Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for affinity='rbf'.

eigen_tol [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when eigen_solver='arpack'.

assign_labels [[‘kmeans’, ‘discretize’], default: ‘kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

degree [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

coeff0 [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params [dictionary of string to any, optional] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

affinity_matrix_ [array-like, shape (n_samples, n_samples)] Affinity matrix used for clustering. Available only if after calling fit.

labels_ [array, shape (n_samples,)] Labels of each point

Notes

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values mean very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

\[
\exp(- \text{dist} \cdot \delta^2 / (2 \cdot \delta^2))
\]

Where \(\delta\) is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points. If the pyamg package is installed, it is used: this greatly speeds up computation.

References

Examples

```python
>>> from sklearn.cluster import SpectralClustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralClustering(n_clusters=2, ...
... assign_labels="discretize", ...
... random_state=0).fit(X)
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
>>> clustering
SpectralClustering(assign_labels='discretize', n_clusters=2, random_state=0)
```

Methods

- `fit(self, X[, y])` Perform spectral clustering from features, or affinity matrix.
- `fit_predict(self, X[, y])` Perform spectral clustering from features, or affinity matrix, and return cluster labels.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, \*\*params)` Set the parameters of this estimator.

```python
__init__(self, n_clusters=8, eigen_solver=None, n_components=None, random_state=None, n_init=10, gamma=1.0, affinity='rbf', n_neighbors=10, eigen_tol=0.0, assign_labels='kmeans', degree=3, coef0=1, kernel_params=None, n_jobs=None)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y=None)
```
Perform spectral clustering from features, or affinity matrix.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse matrix is provided in a format other than `csr_matrix`, `csc_matrix`, or `coo_matrix`, it will be converted into a sparse `csr_matrix`.
- `y` [Ignored] Not used, present here for API consistency by convention.

**Returns**

- `self`

```python
fit_predict (self, X, y=None)
```
Perform spectral clustering from features, or affinity matrix, and return cluster labels.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between
instances if affinity='precomputed'. If a sparse matrix is provided in a format other than csr_matrix, csc_matrix, or coo_matrix, it will be converted into a sparse csr_matrix.

y [Ignored] Not used, present here for API consistency by convention.

Returns
labels [ndarray, shape (n_samples,)] Cluster labels.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
deepl [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

Examples using sklearn.cluster.SpectralClustering

- Comparing different clustering algorithms on toy datasets

sklearn.cluster.SpectralBiclustering
class sklearn.cluster.SpectralBiclustering (n_clusters=3, method='bistochastic', n_components=6, n_best=3, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs=None, random_state=None)

Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure. Read more in the User Guide.

Parameters
**n_clusters** [int or tuple (n_row_clusters, n_column_clusters), default=3] The number of row and column clusters in the checkerboard structure.

**method** [{‘bistochastic’, ‘scale’, ‘log’}, default=’bistochastic’] Method of normalizing and converting singular vectors into biclusters. May be one of ‘scale’, ‘bistochastic’, or ‘log’. The authors recommend using ‘log’. If the data is sparse, however, log normalization will not work, which is why the default is ‘bistochastic’.

**n_components** [int, default=6] Number of singular vectors to check.

**n_best** [int, default=3] Number of best singular vectors to which to project the data for clustering.

**svd_method** [{‘randomized’, ‘arpack’}, default=’randomized’] Selects the algorithm for finding singular vectors. May be ‘randomized’ or ‘arpack’. If ‘randomized’, uses `randomized_svd` which may be faster for large matrices. If ‘arpack’, uses `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.

**n_svd_vecs** [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to `ncv` when `svd_method=arpack` and `n_oversamples` when `svd_method` is ‘randomized’.

**mini_batch** [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

**init** [{‘k-means++’, ‘random’} or ndarray of (n_clusters, n_features), default=’k-means++’] Method for initialization of k-means algorithm; defaults to ‘k-means++’.

**n_init** [int, default=10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

**n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random_state** [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See *Glossary*.

**Attributes**

**rows_** [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling `fit`.

**columns_** [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like `rows`.

**row_labels_** [array-like of shape (n_rows,)] Row partition labels.

**column_labels_** [array-like of shape (n_cols,)] Column partition labels.
References

- Kluger, Yuval, et. al., 2003. Spectral biclustering of microarray data: coclustering genes and conditions.

Examples

```python
>>> from sklearn.cluster import SpectralBiclustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralBiclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 1], dtype=int32)
>>> clustering
SpectralBiclustering(n_clusters=2, random_state=0)
```

Methods

- `fit(self, X[, y])` Creates a biclustering for X.
- `get_indices(self, i)` Row and column indices of the i’th bicluster.
- `get_params(self[, deep])` Get parameters for this estimator.
- `get_shape(self, i)` Shape of the i’th bicluster.
- `get_submatrix(self, i, data)` Return the submatrix corresponding to bicluster i.
- `set_params(self, **params)` Set the parameters of this estimator.

```
__init__(self, n_clusters=3, method='bistochastic', n_components=6, n_best=3,
         svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++',
         n_init=10, n_jobs=None, random_state=None)
```

Initialize self. See help(type(self)) for accurate signature.

- `biclusters_` Convenient way to get row and column indicators together.

```
fit (self, X, y=None)
```

Creates a biclustering for X.

Parameters

- `X` [array-like, shape (n_samples, n_features)]
- `y` [Ignored]

- `get_indices (self, i)` Row and column indices of the i’th bicluster.

Parameters

- `i` [int] The index of the cluster.

Returns

7.3. sklearn.cluster: Clustering
row_ind  [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind  [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

dee [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

get_shape (self, i)
Shape of the i’th bicluster.

Parameters

i  [int] The index of the cluster.

Returns

shape  [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix (self, i, data)
Return the submatrix corresponding to bicluster i.

Parameters

i  [int] The index of the cluster.

data  [array] The data.

Returns

submatrix  [array] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

Examples using sklearn.cluster.SpectralBiclustering

• A demo of the Spectral Biclustering algorithm
sklearn.cluster.SpectralCoclustering

class sklearn.cluster.SpectralCoclustering(n_clusters=3, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs=None, random_state=None)

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array X to solve the relaxed normalized cut of the bipartite graph created from X as follows: the edge between row vertex i and column vertex j has weight X[i, j].

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the User Guide.

Parameters

n_clusters [int, default=3] The number of biclusters to find.

svd_method [‘randomized’, ‘arpack’, default=’randomized’] Selects the algorithm for finding singular vectors. May be ‘randomized’ or ‘arpack’. If ‘randomized’, use sklearn.utils.extmath.randomized_svd, which may be faster for large matrices. If ‘arpack’, use scipy.sparse.linalg.svds, which is more accurate, but possibly slower in some cases.

n_svd_vecs [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to ncv when svd_method=arpack and n_oversamples when svd_method is ‘randomized’.

mini_batch [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

init [‘k-means++’, ‘random’, or ndarray of shape (n_clusters, n_features), default=’k-means++‘] Method for initialization of k-means algorithm; defaults to ‘k-means++’.

n_init [int, default=10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See Glossary.

Attributes

rows_ [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling fit.

columns_ [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like rows.

row_labels_ [array-like of shape (n_rows,)] The bicluster label of each row.
column_labels_ [array-like of shape (n_cols,)] The bicluster label of each column.

References

Examples

```python
>>> from sklearn.cluster import SpectralCoclustering
>>> import numpy as np

>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
               [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralCoclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([0, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 0], dtype=int32)
>>> clustering
SpectralCoclustering(n_clusters=2, random_state=0)
```

Methods

- `fit(self, X[, y])` Creates a biclustering for X.
- `get_indices(self, i)` Row and column indices of the i’th bicluster.
- `get_params(self[, deep])` Get parameters for this estimator.
- `get_shape(self, i)` Shape of the i’th bicluster.
- `get_submatrix(self, i, data)` Return the submatrix corresponding to bicluster i.
- `set_params(self,**params)` Set the parameters of this estimator.

```
__init__(self, n_clusters=3, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs=None, random_state=None)
```

Initialize self. See help(type(self)) for accurate signature.

property biclusters_

Convenient way to get row and column indicators together.

Returns the rows_ and columns_ members.

```
fit (self, X, y=None)
```

Creates a biclustering for X.

Parameters

- `X` [array-like, shape (n_samples, n_features)]
- `y` [Ignored]
Returns

row_ind [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_shape (self, i)
Shape of the i’th bicluster.

Parameters

i [int] The index of the cluster.

Returns

shape [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix (self, i, data)
Return the submatrix corresponding to bicluster i.

Parameters

i [int] The index of the cluster.

data [array] The data.

Returns

submatrix [array] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

**sklearn.cluster.affinity_propagation**

Perform Affinity Propagation Clustering of data

Read more in the User Guide.

Parameters

- `S` [array-like, shape (n_samples, n_samples)] Matrix of similarities between points
- `preference` [array-like, shape (n_samples,)] or float, optional] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.
- `convergence_iter` [int, optional, default: 15] Number of iterations with no change in the number of estimated clusters that stops the convergence.
- `max_iter` [int, optional, default: 200] Maximum number of iterations
- `damping` [float, optional, default: 0.5] Damping factor between 0.5 and 1.
- `copy` [boolean, optional, default: True] If copy is False, the affinity matrix is modified in place by the algorithm, for memory efficiency
- `verbose` [boolean, optional, default: False] The verbosity level
return_n_iter  [bool, default False] Whether or not to return the number of iterations.

Returns

cluster_centers_indices  [array, shape (n_clusters,)] index of clusters centers
labels  [array, shape (n_samples,)] cluster labels for each point
n_iter  [int] number of iterations run. Returned only if return_n_iter is set to True.

Notes

For an example, see examples/cluster/plot_affinity_propagation.py.

When the algorithm does not converge, it returns an empty array as cluster_center_indices and -1 as label for each training sample.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, a single cluster center and label 0 for every sample will be returned. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

References

Examples using sklearn.cluster.affinity_propagation

- Visualizing the stock market structure

sklearn.cluster.cluster_optics_dbscan

sklearn.cluster.cluster_optics_dbscan(reachability, core_distances, ordering, eps)
Performs DBSCAN extraction for an arbitrary epsilon.

Extracting the clusters runs in linear time. Note that this results in labels_ which are close to a DBSCAN with similar settings and eps, only if eps is close to max_eps.

Parameters

reachability  [array, shape (n_samples,)] Reachability distances calculated by OPTICS (reachability_)
core_distances  [array, shape (n_samples,)] Distances at which points become core (core_distances_)
ordering  [array, shape (n_samples,)] OPTICS ordered point indices (ordering_)
eps  [float] DBSCAN eps parameter. Must be set to < max_eps. Results will be close to DBSCAN algorithm if eps and max_eps are close to one another.

Returns

labels_  [array, shape (n_samples,)] The estimated labels.
Examples using `sklearn.cluster.cluster_optics_dbscan`

- Demo of OPTICS clustering algorithm

`sklearn.cluster.cluster_optics_xi`

Automatically extract clusters according to the Xi-steep method.

**Parameters**

- `reachability` [array, shape (n_samples,)] Reachability distances calculated by OPTICS
- `predecessor` [array, shape (n_samples,)] Predecessors calculated by OPTICS.
- `ordering` [array, shape (n_samples,)] OPTICS ordered point indices
- `min_samples` [int > 1 or float between 0 and 1] The same as the min_samples given to OPTICS. Up and down steep regions can’t have more then min_samples consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).
- `min_cluster_size` [int > 1 or float between 0 and 1 (default=None)] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If None, the value of min_samples is used instead.
- `xi` [float, between 0 and 1, optional (default=0.05)] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi.
- `predecessor_correction` [bool, optional (default=True)] Correct clusters based on the calculated predecessors.

**Returns**

- `labels` [array, shape (n_samples)] The labels assigned to samples. Points which are not included in any cluster are labeled as -1.
- `clusters` [array, shape (n_clusters, 2)] The list of clusters in the form of [start, end] in each row, with all indices inclusive. The clusters are ordered according to (end, -start) (ascending) so that larger clusters encompassing smaller clusters come after such nested smaller clusters. Since labels does not reflect the hierarchy, usually len(clusters) > np.unique(labels).

`sklearn.cluster.compute_optics_graph`

Computes the OPTICS reachability graph.

Read more in the User Guide.

**Parameters**

- `X` [array, shape (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'.] A feature array, or array of distances between samples if metric='precomputed'
min_samples [int > 1 or float between 0 and 1] The number of samples in a neighborhood for a point to be considered as a core point. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

max_eps [float, optional (default=np.inf)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of np.inf will identify clusters across all scales; reducing max_eps will result in shorter run times.

metric [string or callable, optional (default=’minkowski’)] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used. If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string. If metric is “precomputed”, X is assumed to be a distance matrix and must be square.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.

p [integer, optional (default=2)] Parameter for the Minkowski metric from sklearn.metrics.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, optional (default=None)] Additional keyword arguments for the metric function.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:
- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, optional (default=30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

ordering_ [array, shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [array, shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use clust.core_distances_[clust.ordering_] to access in cluster order.
reachability_ [array, shape (n_samples,)] Reachability distances per sample, indexed by object order. Use clust.reachability_[clust.ordering_] to access in cluster order.

predecessor_ [array, shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

References

[1]

sklearn.cluster.dbscan

**sklearn.cluster.dbscan** *(X, eps=0.5, min_samples=5, metric='minkowski', metric_params=None, algorithm='auto', leaf_size=30, p=2, sample_weight=None, n_jobs=None)*

Perform DBSCAN clustering from vector array or distance matrix.

Read more in the *User Guide*.

**Parameters**

- **X** [array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape (n_samples, n_samples)] A feature array, or array of distances between samples if metric='precomputed'.
- **eps** [float, optional] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.
- **min_samples** [int, optional] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.
- **metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by sklearn.metrics.pairwise_distances for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a Glossary, in which case only “nonzero” elements may be considered neighbors.
- **metric_params** [dict, optional] Additional keyword arguments for the metric function.

New in version 0.19.

- **algorithm** [[‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], optional] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.
- **leaf_size** [int, optional (default = 30)] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
- **p** [float, optional] The power of the Minkowski metric to be used to calculate distance between points.
- **sample_weight** [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.
n_jobs: [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

core_samples: [array [n_core_samples]] Indices of core samples.

labels: [array [n_samples]] Cluster labels for each point. Noisy samples are given the label -1.

See also:

DBSCAN: An estimator interface for this clustering algorithm.

OPTICS: A similar estimator interface clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see examples/cluster/plot_dbscan.py.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n). It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using NearestNeighbors.radius_neighbors_graph with mode='distance', then using metric='precomputed' here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use sample_weight instead.

cluster.optics provides a similar clustering with lower memory usage.

References

sklearn.cluster.estimate_bandwidth

sklearn.cluster.estimate_bandwidth(X, quantile=0.3, n_samples=None, random_state=0, n_jobs=None)

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in n_samples. For large datasets, it’s wise to set that parameter to a small value.

Parameters

X: [array-like of shape (n_samples, n_features)] Input points.

quantile: [float, default 0.3] should be between [0, 1] 0.5 means that the median of all pairwise distances is used.
n_samples  [int, optional] The number of samples to use. If not given, all samples are used.

random_state  [int, RandomState instance or None (default)] The generator used to randomly select the samples from input points for bandwidth estimation. Use an int to make the randomness deterministic. See Glossary.

n_jobs  [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

bandwidth  [float] The bandwidth parameter.

Examples using sklearn.cluster.estimate_bandwidth

- A demo of the mean-shift clustering algorithm
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.k_means

sklearn.cluster.k_means(X, n_clusters, sample_weight=None, init='k-means++', precompute_distances='auto', n_init=10, max_iter=300, verbose=False, tol=0.0001, random_state=None, copy_x=True, n_jobs=None, algorithm='auto', return_n_iter=False)

K-means clustering algorithm.

Parameters

X  [array-like or sparse matrix, shape (n_samples, n_features)] The observations to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

n_clusters  [int] The number of clusters to form as well as the number of centroids to generate.

sample_weight  [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

init  [{'k-means++', 'random', or ndarray, or a callable}, optional] Method for initialization, default to ‘k-means++’:

‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

‘random’ : choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

If a callable is passed, it should take arguments X, k and a random state and return an initialization.

precompute_distances  [{'auto', True, False}] Precompute distances (faster but takes more memory).

‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
True : always precompute distances
False : never precompute distances

n_init [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

max_iter [int, optional, default 300] Maximum number of iterations of the k-means algorithm to run.

verbose [boolean, optional] Verbosity mode.

tol [float, optional] The relative increment in the results before declaring convergence.

random_state [int, RandomState instance or None (default)] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See Glossary.

copy_x [bool, optional] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True (default), then the original data is not modified, ensuring X is C-contiguous. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean, in this case it will also not ensure that data is C-contiguous which may cause a significant slowdown.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

algorithm [“auto”, “full” or “elkan”, default=”auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. “auto” chooses “elkan” for dense data and “full” for sparse data.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

centroid [float ndarray with shape (k, n_features)] Centroids found at the last iteration of k-means.

label [integer ndarray with shape (n_samples,)] label[i] is the code or index of the centroid the i’th observation is closest to.

inertia [float] The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

best_n_iter [int] Number of iterations corresponding to the best results. Returned only if return_n_iter is set to True.

sklearn.cluster.mean_shift

sklearn.cluster.mean_shift (X, bandwidth=None, seeds=None, bin_seeding=False, min_bin_freq=1, cluster_all=True, max_iter=300, n_jobs=None)

Perform mean shift clustering of data using a flat kernel.

Read more in the User Guide.

Parameters
X [array-like of shape (n_samples, n_features)] Input data.

If bandwidth is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The sklearn.cluster.estimate_bandwidth function can be used to do this more efficiently.

seeds [array-like of shape (n_seeds, n_features) or None] Point used as initial kernel locations. If None and bin_seeding=False, each data point is used as a seed. If None and bin_seeding=True, see bin_seeding.

bin_seeding [boolean, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if seeds argument is not None.

min_bin_freq [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

cluster_all [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

max_iter [int, default 300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.17: Parallel Execution using n_jobs.

Returns

cluster_centers [array, shape=[n_clusters, n_features]] Coordinates of cluster centers.

labels [array, shape=[n_samples]] Cluster labels for each point.

Notes

For an example, see examples/cluster/plot_mean_shift.py.

sklearn.cluster.spectral_clustering

sklearn.cluster.spectral_clustering(affinity, n_clusters=8, n_components=None, eigen_solver=None, random_state=None, n_init=10, eigen_tol=0.0, assign_labels='kmeans')

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance, when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the User Guide.
Parameters

affinity [array-like or sparse matrix, shape: (n_samples, n_samples)] The affinity matrix describing the relationship of the samples to embed. Must be symmetric.

Possible examples:

- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,
- symmetric k-nearest neighbours connectivity matrix of the samples.

n_clusters [integer, optional] Number of clusters to extract.

n_components [integer, optional, default is n_clusters] Number of eigen vectors to use for the spectral embedding

eigen_solver [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities

random_state [int, RandomState instance or None (default)] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == ‘amg’ and by the K-Means initialization. Use an int to make the randomness deterministic. See Glossary.

n_init [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

eigen_tol [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

assign_labels [{‘kmeans’, ‘discretize’}, default: ‘kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the ‘Multiclass spectral clustering’ paper referenced below for more details on the discretization approach.

Returns

labels [array of integers, shape: n_samples] The labels of the clusters.

Notes

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for k=2: it is a normalized spectral clustering.

References

7.3. sklearn.cluster: Clustering
Examples using `sklearn.cluster.spectral_clustering`

- Segmenting the picture of greek coins in regions
- Spectral clustering for image segmentation

`sklearn.cluster.ward_tree`

`sklearn.cluster.ward_tree(X, connectivity=None, n_clusters=None, return_distance=False)`

Ward clustering based on a Feature matrix.

- Recursively merges the pair of clusters that minimally increases within-cluster variance.
- The inertia matrix uses a Heapq-based representation.
- This is the structured version, that takes into account some topological structure between samples.
- Read more in the *User Guide*.

**Parameters**

- **X** [array, shape (n_samples, n_features)] feature matrix representing n_samples samples to be clustered
- **connectivity** [sparse matrix (optional).] connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e., the Ward algorithm is unstructured.
- **n_clusters** [int (optional)] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the ‘children’ output is of limited use, and the ‘parents’ output should rather be used. This option is valid only when specifying a connectivity matrix.
- **return_distance** [bool (optional)] If True, return the distance between the clusters.

**Returns**

- **children** [2D array, shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children[i - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i
- **n_connected_components** [int] The number of connected components in the graph.
- **n_leaves** [int] The number of leaves in the tree
- **parents** [1D array, shape (n_nodes, ) or None] The parent of each node. Only returned when a connectivity matrix is specified, elsewhere ‘None’ is returned.
- **distances** [1D array, shape (n_nodes-1, )] Only returned if return_distance is set to True (for compatibility). The distances between the centers of the nodes. distances[i] corresponds to a weighted euclidean distance between the nodes children[i, 1] and children[i, 2]. If the nodes refer to leaves of the tree, then distances[i] is their unweighted euclidean distance. Distances are updated in the following way (from scipy.hierarchy.linkage):
The new entry \( d(u, v) \) is computed as follows,
\[
d(u, v) = \sqrt{\frac{|v| + |s|}{T} d(v, s)^2 + \frac{|v| + |t|}{T} d(v, t)^2 - \frac{|v|}{T} d(s, t)^2}
\]
where \( u \) is the newly joined cluster consisting of clusters \( s \) and \( t \), \( v \) is an unused cluster in the forest, \( T = |v| + |s| + |t| \), and \( |*| \) is the cardinality of its argument. This is also known as the incremental algorithm.

### 7.4 sklearn.compose: Composite Estimators

Meta-estimators for building composite models with transformers

In addition to its current contents, this module will eventually be home to refurbished versions of Pipeline and FeatureUnion.

**User guide:** See the Pipelines and composite estimators section for further details.

```python
comp_columnTransformer(transformers[, ...])
```
Applies transformers to columns of an array or pandas DataFrame.

```python
comp_transformedTargetRegressor(...)  
```
Meta-estimator to regress on a transformed target.

### 7.4.1 sklearn.compose.ColumnTransformer

```
class sklearn.compose.ColumnTransformer(transformers,       remainder='drop',
                                         sparse_threshold=0.3,  n_jobs=None,  transformer_weights=None, verbose=False)
```
Applies transformers to columns of an array or pandas DataFrame.

This estimator allows different columns or column subsets of the input to be transformed separately and the features generated by each transformer will be concatenated to form a single feature space. This is useful for heterogeneous or columnar data, to combine several feature extraction mechanisms or transformations into a single transformer.

Read more in the User Guide.

New in version 0.20.

**Parameters**

- **transformers** [list of tuples] List of (name, transformer, column(s)) tuples specifying the transformer objects to be applied to subsets of the data.
- **name** [string] Like in Pipeline and FeatureUnion, this allows the transformer and its parameters to be set using set_params and searched in grid search.
- **transformer** [estimator or {'passthrough', 'drop'}] Estimator must support fit and transform. Special-cased strings ‘drop’ and ‘passthrough’ are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.
- **column(s)** [string or int, array-like of string or int, slice, boolean mask array or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where transformer expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data \( x \) and can
return any of the above. To select multiple columns by name or dtype, you can use `make_column_transformer`.

**remainder** [({'drop', 'passthrough'}) or estimator, default 'drop'] By default, only the specified columns in `transformers` are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying `remainder='passthrough'`, all remaining columns that were not specified in `transformers` will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting `remainder` to be an estimator, the remaining non-specified columns will use the `remainder` estimator. The estimator must support `fit` and `transform`. Note that using this feature requires that the DataFrame columns input at `fit` and `transform` have identical order.

**sparse_threshold** [float, default = 0.3] If the output of the different transformers contains sparse matrices, these will be stacked as a sparse matrix if the overall density is lower than this value. Use `sparse_threshold=0` to always return dense. When the transformed output consists of all dense data, the stacked result will be dense, and this keyword will be ignored.

**n_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**transformer_weights** [dict, optional] Multiplicative weights for features per transformer. The output of the transformer is multiplied by these weights. Keys are transformer names, values the weights.

**verbose** [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Attributes**

**transformers_** [list] The collection of fitted transformers as tuples of (name, fitted_transformer, column). `fitted_transformer` can be an estimator, ‘drop’, or ‘passthrough’. In case there were no columns selected, this will be the unfitted transformer. If there are remaining columns, the final element is a tuple of the form: (‘remainder’, transformer, remaining_columns) corresponding to the `remainder` parameter. If there are remaining columns, then len(transformers_)==len(transformers)+1, otherwise len(transformers_)==len(transformers).

**named_transformers_** [Bunch object, a dictionary with attribute access] Access the fitted transformer by name.

**sparse_output_** [boolean] Boolean flag indicating whether the output of `transform` is a sparse matrix or a dense numpy array, which depends on the output of the individual transformers and the `sparse_threshold` keyword.

**See also:**

`sklearn.compose.make_column_transformer` convenience function for combining the outputs of multiple transformer objects applied to column subsets of the original feature space.

`sklearn.compose.make_column_selector` convenience function for selecting columns based on datatype or the columns name with a regex pattern.

**Notes**

The order of the columns in the transformed feature matrix follows the order of how the columns are specified in the `transformers` list. Columns of the original feature matrix that are not specified are dropped from the
resulting transformed feature matrix, unless specified in the `passthrough` keyword. Those columns specified with `passthrough` are added at the right to the output of the transformers.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.compose import ColumnTransformer
>>> from sklearn.preprocessing import Normalizer

>>> ct = ColumnTransformer([("norm1", Normalizer(norm='l1'), [0, 1]),
                          ("norm2", Normalizer(norm='l1'), slice(2, 4))])

>>> X = np.array([[0., 1., 2., 2.],
                [1., 1., 0., 1.]])

>>> # Normalizer scales each row of X to unit norm. A separate scaling
>>> # is applied for the two first and two last elements of each
>>> # row independently.
>>> ct.fit_transform(X)
array([[0. , 1. , 0.5, 0.5],
       [0.5, 0.5, 0. , 1. ]])
```

**Methods**

- `fit(self, X[, y])` Fit all transformers using X.
- `fit_transform(self, X[, y])` Fit all transformers, transform the data and concatenate results.
- `get_feature_names(self)` Get feature names from all transformers.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, **kwargs)` Set the parameters of this estimator.
- `transform(self, X)` Transform X separately by each transformer, concatenate results.

```python
__init__(self, transformers, remainder='drop', sparse_threshold=0.3, n_jobs=None, transformer_weights=None, verbose=False)
```

Initialize self. See help(type(self)) for accurate signature.

`fit (self, X, y=None)`

Fit all transformers using X.

**Parameters**

- `X` [array-like or DataFrame of shape [n_samples, n_features]] Input data, of which specified subsets are used to fit the transformers.

**Returns**

- `self` [ColumnTransformer] This estimator

`fit_transform(self, X, y=None)`

Fit all transformers, transform the data and concatenate results.

**Parameters**

- `X` [array-like or DataFrame of shape [n_samples, n_features]] Input data, of which specified subsets are used to fit the transformers.
y [array-like, shape (n_samples, ...), optional] Targets for supervised learning.

Returns

X_t [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

get_feature_names (self)
Get feature names from all transformers.

Returns

feature_names [list of strings] Names of the features produced by transform.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property named_transformers_
Access the fitted transformer by name.

Read-only attribute to access any transformer by given name. Keys are transformer names and values are the fitted transformer objects.

set_params (self, **kwargs)
Set the parameters of this estimator.

Valid parameter keys can be listed with get_params().

Returns

self

transform (self, X)
Transform X separately by each transformer, concatenate results.

Parameters

X [array-like or DataFrame of shape [n_samples, n_features]] The data to be transformed by subset.

Returns

X_t [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

Examples using sklearn.compose.ColumnTransformer

- Permutation Importance vs Random Forest Feature Importance (MDI)
- Column Transformer with Mixed Types
- Column Transformer with Heterogeneous Data Sources
7.4.2 sklearn.compose.TransformedTargetRegressor

```python
class sklearn.compose.TransformedTargetRegressor (regressor=None, transformer=None, func=None, inverse_func=None, check_inverse=True)
```

Meta-estimator to regress on a transformed target.

Useful for applying a non-linear transformation to the target $y$ in regression problems. This transformation can be given as a Transformer such as the QuantileTransformer or as a function and its inverse such as $\log$ and $\exp$.

The computation during `fit` is:

```python
regressor.fit(X, func(y))
```

or:

```python
regressor.fit(X, transformer.transform(y))
```

The computation during `predict` is:

```python
inverse_func(regressor.predict(X))
```

or:

```python
transformer.inverse_transform(regressor.predict(X))
```

Read more in the *User Guide*.

**Parameters**

- `regressor` [object, default=LinearRegression()] Regressor object such as derived from `RegressorMixin`. This regressor will automatically be cloned each time prior to fitting.

- `transformer` [object, default=None] Estimator object such as derived from `TransformerMixin`. Cannot be set at the same time as `func` and `inverse_func`. If `transformer` is `None` as well as `func` and `inverse_func`, the transformer will be an identity transformer. Note that the transformer will be cloned during fitting. Also, the transformer is restricting $y$ to be a numpy array.

- `func` [function, optional] Function to apply to $y$ before passing to `fit`. Cannot be set at the same time as `transformer`. The function needs to return a 2-dimensional array. If `func` is `None`, the function used will be the identity function.

- `inverse_func` [function, optional] Function to apply to the prediction of the regressor. Cannot be set at the same time as `transformer` as well. The function needs to return a 2-dimensional array. The inverse function is used to return predictions to the same space of the original training labels.

- `check_inverse` [bool, default=True] Whether to check that `transform` followed by `inverse_transform` or `func` followed by `inverse_func` leads to the original targets.

**Attributes**

- `transformer_` [object] Transformer used in `fit` and `predict`.
Notes

Internally, the target $y$ is always converted into a 2-dimensional array to be used by scikit-learn transformers. At the time of prediction, the output will be reshaped to a have the same number of dimensions as $y$.

See examples/compose/plot_transformed_target.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.compose import TransformedTargetRegressor
... tt = TransformedTargetRegressor(regressor=LinearRegression(),
...     func=np.log, inverse_func=np.exp)
>>> X = np.arange(4).reshape(-1, 1)
>>> y = np.exp(2 * X).ravel()
>>> tt.fit(X, y)
TransformedTargetRegressor(...)
>>> tt.score(X, y)
1.0
>>> tt.regressor_.coef_
array([2.])
```

Methods

- `fit` (self, X, y,**fit_params) Fit the model according to the given training data.
- `get_params`(self[, deep]) Get parameters for this estimator.
- `predict`(self, X) Predict using the base regressor, applying inverse.
- `score`(self, X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.
- `set_params`(self, **params) Set the parameters of this estimator.

- `__init__`(self, regressor=None, transformer=None, func=None, inverse_func=None, check_inverse=True) Initialize self. See help(type(self)) for accurate signature.

- `fit`(self, X, y, **fit_params) Fit the model according to the given training data.

  Parameters

  - `X` [[array-like, sparse matrix], shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
  - `y` [array-like, shape (n_samples,)] Target values.

  **fit_params** [dict of string -> object] Parameters passed to the fit method of the underlying regressor.

  Returns

  - `self` [object]

- `get_params`(self, deep=True) Get parameters for this estimator.

  Parameters

  - `deep` [bool]

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(self, X)*

Predict using the base regressor, applying inverse.

The regressor is used to predict and the `inverse_func` or `inverse_transform` is applied before returning the prediction.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

**Returns**

**y_hat** [array, shape = (n_samples,)] Predicted values.

**score** *(self, X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean()}) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

**score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**
Examples using `sklearn.compose.TransformedTargetRegressor`

- **Effect of transforming the targets in regression model**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compose.make_column_transformer()</code></td>
<td>Construct a ColumnTransformer from the given transformers.</td>
</tr>
<tr>
<td><code>compose.make_column_selector([pattern, ...])</code></td>
<td>Create a callable to select columns to be used with ColumnTransformer.</td>
</tr>
</tbody>
</table>

### 7.4.3 sklearn.compose.make_column_transformer

**sklearn.compose.make_column_transformer(*transformers, **kwargs)**

Construct a ColumnTransformer from the given transformers.

This is a shorthand for the ColumnTransformer constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting with `transformer_weights`.

Read more in the *User Guide*.

**Parameters**

- **transformers** [tuples] Tuples of the form (transformer, column(s)) specifying the transformer objects to be applied to subsets of the data.
- **transformer** [estimator or {'passthrough', 'drop'}] Estimator must support `fit` and `transform`. Special-cased strings ‘drop’ and ‘passthrough’ are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.
- **column(s)** [string or int, array-like of string or int, slice, boolean mask array or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where transformer expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data X and can return any of the above.
- **remainder** [‘drop’, ‘passthrough’) or estimator, default ‘drop’) By default, only the specified columns in transformers are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying remainder='passthrough', all remaining columns that were not specified in transformers will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting remainder to be an estimator, the remaining non-specified columns will use the remainder estimator. The estimator must support `fit` and `transform`.
- **sparse_threshold** [float, default = 0.3] If the transformed output consists of a mix of sparse and dense data, it will be stacked as a sparse matrix if the density is lower than this value. Use sparse_threshold=0 to always return dense. When the transformed output consists of all sparse or all dense data, the stacked result will be sparse or dense, respectively, and this keyword will be ignored.
- **n_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See *Glossary* for more details.
verbose [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

Returns

ct [ColumnTransformer]

See also:

sklearn.compose.ColumnTransformer Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

Examples

```python
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer

make_column_transformer(
    ... (StandardScaler(), 'numerical_column'),
    ... (OneHotEncoder(), 'categorical_column'))

ColumnTransformer(transformers=[('standardscaler', StandardScaler(...),
    ['numerical_column']),
    ('onehotencoder', OneHotEncoder(...),
    ['categorical_column'])])
```

7.4.4 sklearn.compose.make_column_selector

sklearn.compose.make_column_selector(pattern=None, dtype_include=None, dtype_exclude=None)

Create a callable to select columns to be used with ColumnTransformer.

make_column_selector can select columns based on datatype or the columns name with a regex. When using multiple selection criteria, all criteria must match for a column to be selected.

Parameters

pattern [str, default=None] Name of columns containing this regex pattern will be included. If None, column selection will not be selected based on pattern.

dtype_include [column dtype or list of column dtypes, default=None] A selection of dtypes to include. For more details, see pandas.DataFrame.select_dtypes.

dtype_exclude [column dtype or list of column dtypes, default=None] A selection of dtypes to exclude. For more details, see pandas.DataFrame.select_dtypes.

Returns

selector [callable] Callable for column selection to be used by ColumnTransformer.

See also:

sklearn.compose.ColumnTransformer Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

Examples
```python
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> from sklearn.compose import make_column_selector
>>> import pandas as pd
# doctest: +SKIP

>>> X = pd.DataFrame({'city': ['London', 'London', 'Paris', 'Sallisaw'],
...                   'rating': [5, 3, 4, 5]})
# doctest: +SKIP

>>> ct = make_column_transformer(
...                                (StandardScaler(),
...                                make_column_selector(dtype_include=np.number)),  # rating
...                                (OneHotEncoder(),
...                                make_column_selector(dtype_include=object)))  # city

>>> ct.fit_transform(X)
# doctest: +SKIP
array([[ 0.90453403, 1. , 0. , 0. ],
       [-1.50755672, 1. , 0. , 0. ],
       [-0.30151134, 0. , 1. , 0. ],
       [ 0.90453403, 0. , 0. , 1. ]])
```

## 7.5 `sklearn.covariance`: Covariance Estimators

The `sklearn.covariance` module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance estimation is closely related to the theory of Gaussian Graphical Models.

**User guide:** See the Covariance estimation section for further details.

### 7.5.1 `sklearn.covariance.EmpiricalCovariance`

**class** `sklearn.covariance.EmpiricalCovariance` *(store_precision=True, assume_centered=False)*

Maximum likelihood covariance estimator

Read more in the *User Guide*.

**Parameters**

- `store_precision` [bool] Specifies if the estimated precision is stored.
- `assume_centered` [bool] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.
Attributes

- **location_** [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.
- **covariance_** [2D ndarray, shape (n_features, n_features)] Estimated covariance matrix.
- **precision_** [2D ndarray, shape (n_features, n_features)] Estimated pseudo-inverse matrix. (stored only if store_precision is True)

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import EmpiricalCovariance
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
                      [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
                            cov=real_cov,
                            size=500)
>>> cov = EmpiricalCovariance().fit(X)
>>> cov.covariance_
array([[0.7569..., 0.2818...],
       [0.2818..., 0.3928...]])
>>> cov.location_
array([0.0622..., 0.0193...])
```

Methods

- **error_norm**(self, comp_cov[, norm, scaling, ...]) Computes the Mean Squared Error between two covariance estimators.
- **fit**(self, X[, y]) Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.
- **get_params**(self[, deep]) Get parameters for this estimator.
- **get_precision**(self) Getter for the precision matrix.
- **mahalanobis**(self, X) Computes the squared Mahalanobis distances of given observations.
- **score**(self, X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.
- **set_params**(self, **params) Set the parameters of this estimator.

__init__(self, store_precision=True, assume_centered=False) Initialize self. See help(type(self)) for accurate signature.

**error_norm**(self, comp_cov, norm='frobenius', scaling=True, squared=True) Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’
(default): \(\sqrt{\text{tr}(A^tA)}\) - 'spectral': \(\sqrt{\text{max(eigenvalues}(A^tA))}\) where A is the error (\(\text{comp\_cov} - \text{self\_covariance}\_\)).

**scaling** [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
The Mean Squared Error (in the sense of the Frobenius norm) between
self and comp\_cov covariance estimators.

**fit** (self, X, y=None)
Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

Parameters
X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y not used, present for API consistence purpose.

Returns
self [object]

**get_params** (self, deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

**get_precision** (self)
Getter for the precision matrix.

Returns
precision_ [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (self, X)
Computes the squared Mahalanobis distances of given observations.

Parameters
X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns
dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

**score** (self, X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters
X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.covariance.EmpiricalCovariance

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate

7.5.2 sklearn.covariance.EllipticEnvelope

class sklearn.covariance.EllipticEnvelope (store_precision=True, assume_centered=False, support_fraction=None, contamination=0.1, random_state=None)

An object for detecting outliers in a Gaussian distributed dataset.

Read more in the User Guide.

Parameters

store_precision [boolean, optional (default=True)] Specify if the estimated precision is stored.

assume_centered [boolean, optional (default=False)] If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction [float in (0., 1.), optional (default=None)] The proportion of points to be included in the support of the raw MCD estimate. If None, the minimum value of support_fraction will be used within the algorithm: \[ \frac{n_{sample} + n_{features} + 1}{2}. \]

contamination [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set.
random_state [int, RandomState instance or None, optional (default=None)] The seed of the
to use when shuffling the data. If int, random_state is the seed used by the random number generator; If
RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState
instance used by np.random.

Attributes

location_ [array-like, shape (n_features,)] Estimated robust location
covariance_ [array-like, shape (n_features, n_features)] Estimated robust covariance matrix
precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored
only if store_precision is True)
support_ [array-like, shape (n_samples,)] A mask of the observations that have been used to
compute the robust estimates of location and shape.
offset_ [float] Offset used to define the decision function from the raw scores. We have the rela-
tion: decision_function = score_samples - offset_. The offset depends
on the contamination parameter and is defined in such a way we obtain the expected number
of outliers (samples with decision function < 0) in training.

See also:

EmpiricalCovariance, MinCovDet

Notes

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In
particular, one will always take care to work with n_samples > n_features ** 2.

References

[R68ae096da0e4-1]

Examples

```python
def import numpy as np
def from sklearn.covariance import EllipticEnvelope
def true_cov = np.array([[.8, .3],
... [.3, .4]])
def X = np.random.RandomState(0).multivariate_normal(mean=[0, 0],
... cov=true_cov,
... size=500)
def cov = EllipticEnvelope(random_state=0).fit(X)
def # predict returns 1 for an inlier and -1 for an outlier
def cov.predict([[0, 0],
... [3, 3]])
def array([[1, -1]])
def cov.covariance_
def array([[0.7411..., 0.2535...],
... [0.2535..., 0.3053...]])
def cov.location_
def array([0.0813..., 0.0427...])
```
Methods

**correct_covariance**(self, data)  
Apply a correction to raw Minimum Covariance Determinant estimates.

**decision_function**(self, X)  
Compute the decision function of the given observations.

**error_norm**(self, comp_cov[, norm, scaling, ...])  
Computes the Mean Squared Error between two covariance estimators.

**fit**(self, X[, y])  
Fit the EllipticEnvelope model.

**fit_predict**(self, X[, y])  
Perform fit on X and returns labels for X.

**get_params**(self[, deep])  
Get parameters for this estimator.

**get_precision**(self)  
Getter for the precision matrix.

**mahalanobis**(self, X)  
Computes the squared Mahalanobis distances of given observations.

**predict**(self, X)  
Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.

**reweight_covariance**(self, data)  
Re-weight raw Minimum Covariance Determinant estimates.

**score**(self, X, y[, sample_weight])  
Returns the mean accuracy on the given test data and labels.

**score_samples**(self, X)  
Compute the negative Mahalanobis distances.

**set_params**(self, **params)  
Set the parameters of this estimator.

__init__ (self, store_precision=True, assume_centered=False, support_fraction=None, contamination=0.1, random_state=None)  
Initialize self. See help(type(self)) for accurate signature.

**correct_covariance**(self, data)  
Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

**Parameters**

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

covariance_corrected [array-like, shape (n_features, n_features)] Corrected robust covariance estimate.

References

[RVD]

decision_function**(self, X)  
Compute the decision function of the given observations.

**Parameters**

X [array-like, shape (n_samples, n_features)]

**Returns**
decision [array-like, shape (n_samples, )] Decision function of the samples. It is equal to the shifted Mahalanobis distances. The threshold for being an outlier is 0, which ensures a compatibility with other outlier detection algorithms.

error_norm (self, comp_cov, norm='frobenius', scaling=True, squared=True)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (self, X, y=None)
Fit the EllipticEnvelope model.

Parameters

X [numpy array or sparse matrix, shape (n_samples, n_features).] Training data

y [Ignored] not used, present for API consistency by convention.

fit_predict (self, X, y=None)
Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

y [ndarray, shape (n_samples,)] 1 for inliers, -1 for outliers.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision (self)
Getter for the precision matrix.
Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

mahalanobis (self, X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

predict (self, X)
Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

is_inlier [array, shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

reweight_covariance (self, data)
Re-weight raw Minimum Covariance Determinant estimates.
Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

Parameters

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

location_reweighted [array-like, shape (n_features, )] Re-weighted robust location estimate.
covariance_reweighted [array-like, shape (n_features, n_features)] Re-weighted robust covariance estimate.
support_reweighted [array-like, type boolean, shape (n_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

References

[RVDriessen]
score (self, X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape (n_samples, n_features)] Test samples.
y [array-like, shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like, shape (n_samples,), optional] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

score_samples (self, X)
Compute the negative Mahalanobis distances.

Parameters
X [array-like, shape (n_samples, n_features)]

Returns
negative_mahal_distances [array-like, shape (n_samples, )] Opposite of the Mahalanobis distances.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

Examples using sklearn.covariance.EllipticEnvelope

• Comparing anomaly detection algorithms for outlier detection on toy datasets
• Outlier detection on a real data set

7.5.3 sklearn.covariance.GraphicalLasso

class sklearn.covariance.GraphicalLasso (alpha=0.01, mode='cd', tol=0.0001, enet_tol=0.0001, max_iter=100, verbose=False, assume_centered=False)

Sparse inverse covariance estimation with an l1-penalized estimator.

Read more in the User Guide.

Parameters
alpha [positive float, default 0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

mode [{‘cd’, ‘lars’}, default ‘cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [positive float, default 1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.
enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, default 100] The maximum number of iterations.

verbose [boolean, default False] If verbose is True, the objective function and dual gap are plotted at each iteration.

assume_centered [boolean, default False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix.

n_iter_ [int] Number of iterations run.

graphical_lasso, GraphicalLassoCV

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLasso
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
                        [0.0, 0.4, 0.0, 0.0],
                        [0.2, 0.0, 0.3, 0.1],
                        [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
                        cov=true_cov,
                        size=200)
>>> cov = GraphicalLasso().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.049, 0.218, 0.019],
       [0.049, 0.364, 0.017, 0.034],
       [0.218, 0.017, 0.322, 0.093],
       [0.019, 0.034, 0.093, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```

Continued on next page
### mahalanobis

**Function**: Computes the squared Mahalanobis distances of given observations.

**Signature**: `mahalanobis(self, X)`

- **Parameters**
  - `self`: Object
  - `X`: array-like of shape (n_samples, n_features)

**Example**

```python
from sklearn import mahalanobis

# Assume X is a 2D array
mahalanobis_distances = mahalanobis(X, MahalanobisObject)
```

### score

**Function**: Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Signature**: `score(self, X_test[, y])`

- **Parameters**
  - `self`: Object
  - `X_test`: array-like of shape (n_samples, n_features)
  - `y`: array-like of shape (n_samples,) (optional)

**Example**

```python
from sklearn import score

# Assume X_test is a 2D array
log_likelihood = score(X_test, GaussianObject)
```

### set_params

**Function**: Set the parameters of this estimator.

**Signature**: `set_params(self, **params)`

- **Parameters**
  - `self`: Object
  - `**params`: mapping of string to any

**Example**

```python
from sklearn import set_params

# Assume ParameterObject is an instance
set_params(ParameterObject, new_params)
```

---

**__init__**

**Function**: Initialize self. See help(type(self)) for accurate signature.

**Signature**: `__init__(self, alpha=0.01, mode='cd', tol=0.0001, enet_tol=0.0001, max_iter=100, verbose=False, assume_centered=False)`

- **Parameters**
  - `self`: Object
  - `alpha`: float (default=0.01)
  - `mode`: str (default='cd')
  - `tol`: float (default=0.0001)
  - `enet_tol`: float (default=0.0001)
  - `max_iter`: int (default=100)
  - `verbose`: bool (default=False)
  - `assume_centered`: bool (default=False)

**Example**

```python
from sklearn import __init_

# Assume ParameterObject is an instance
init(ParameterObject, new_params)
```

### error_norm

**Function**: Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Signature**: `error_norm(self, comp_cov[, norm='frobenius', scaling=True, squared=True])`

- **Parameters**
  - `self`: Object
  - `comp_cov`: array-like of shape (n_features, n_features)
  - `norm`: str (default='frobenius')
    - 'frobenius': sqrt(tr(A^t.A))
    - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).
  - `scaling`: bool (default=True)
    - True: the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
  - `squared`: bool (default=True)
    - True: the squared error norm is returned. If False, the error norm is returned.

**Example**

```python
from sklearn import error_norm

# Assume ParameterObject is an instance
error_norm(ParameterObject, other_covariance)
```

### fit

**Function**: Fits the GraphicalLasso model to X.

**Signature**: `fit(self, X[, y=None])`

- **Parameters**
  - `self`: Object
  - `X`: array-like of shape (n_samples, n_features)
  - `y`: (optional)

**Example**

```python
from sklearn import fit

# Assume ParameterObject is an instance
fit(ParameterObject, X_data)
```

### get_params

**Function**: Get parameters for this estimator.

**Signature**: `get_params(self[, deep=True])`

- **Parameters**
  - `self`: Object
  - `deep`: bool (default=True)

**Example**

```python
from sklearn import get_params

# Assume ParameterObject is an instance
get_params(ParameterObject)
```

### get_precision

**Function**: Getter for the precision matrix.

**Signature**: `get_precision(self)`

- **Parameters**
  - `self`: Object

**Example**

```python
from sklearn import get_precision

# Assume ParameterObject is an instance
get_precision(ParameterObject)
```

---

**The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.**

**fit**

- **Parameters**
  - `self`: Object
  - `X`: array-like of shape (n_samples, n_features)
  - `y`: (optional)

**Example**

```python
from sklearn import fit

# Assume ParameterObject is an instance
fit(ParameterObject, X_data)
```

**get_params**

- **Parameters**
  - `self`: Object
  - `deep`: bool (default=True)

**Example**

```python
from sklearn import get_params

# Assume ParameterObject is an instance
get_params(ParameterObject)
```
mahalanobis (self, X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

score (self, X_test, y=None)
 Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.5.4 sklearn.covariance.GraphicalLassoCV

class sklearn.covariance.GraphicalLassoCV (alphas=4, n_refinements=4, cv=None, tol=0.0001, enet_tol=0.0001, max_iter=100, mode='cd', n_jobs=None, verbose=False, assume_centered=False)

Sparse inverse covariance w/ cross-validated choice of the l1 penalty.

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters

alphas [integer, or list positive float, optional] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details.
**n_refinements**  [strictly positive integer] The number of times the grid is refined. Not used if explicit values of alphas are passed.

**cv**  [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: *cv* default value if None changed from 3-fold to 5-fold.

**tol**  [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

**enet_tol**  [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

**max_iter**  [integer, optional] Maximum number of iterations.

**mode**  [{'cd', 'lars'}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer cd which is more numerically stable.

**n_jobs**  [int or None, optional (default=None)] number of jobs to run in parallel. None means 1 unless in a *joblib.parallel_backend* context. -1 means using all processors. See *Glossary* for more details.

**verbose**  [boolean, optional] If verbose is True, the objective function and duality gap are printed at each iteration.

**assume_centered**  [boolean] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

**Attributes**

- **location_**  [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.
- **covariance_**  [numpy.ndarray, shape (n_features, n_features)] Estimated covariance matrix.
- **precision_**  [numpy.ndarray, shape (n_features, n_features)] Estimated precision matrix (inverse covariance).
- **alpha_**  [float] Penalization parameter selected.
- **cv_alphas_**  [list of float] All penalization parameters explored.
- **grid_scores_**  [2D numpy.ndarray (n_alphas, n_folds)] Log-likelihood score on left-out data across folds.
- **n_iter_**  [int] Number of iterations run for the optimal alpha.

See also:

`graphical_lasso`, `GraphicalLasso`
Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-
validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLassoCV

true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
                      [0.0, 0.4, 0.0, 0.0],
                      [0.2, 0.0, 0.3, 0.1],
                      [0.0, 0.0, 0.1, 0.7]])

np.random.seed(0)
X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
                                  cov=true_cov,
                                  size=200)

cov = GraphicalLassoCV().fit(X)

np.around(cov.covariance_, decimals=3)
array([[0.816, 0.051, 0.220, 0.017],
       [0.051, 0.364, 0.018, 0.036],
       [0.220, 0.018, 0.322, 0.094],
       [0.017, 0.036, 0.094, 0.690]])

np.around(cov.location_, decimals=3)
array([0.073, 0.040, 0.038, 0.143])
```

`__init__` (self, alphas=4, n_refinements=4, cv=None, tol=0.0001, enet_tol=0.0001, max_iter=100, mode='cd', n_jobs=None, verbose=False, assume_centered=False)
Initialize self. See help(type(self)) for accurate signature.

`error_norm` (self, comp_cov[, norm, scaling, squared])
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters
**comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.

**norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \(\sqrt{tr(A^t.A)}\) - ‘spectral’: \(\sqrt{max(eigenvalues(A^t.A))}\) where \(A\) is the error (comp_cov - self.covariance_).

**scaling** [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

**fit** (self, X, y=None)
Fits the GraphicalLasso covariance model to X.

**Parameters**

- **X** [ndarray, shape (n_samples, n_features)] Data from which to compute the covariance estimate
- **y** [(ignored)]

**get_params** (self, deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**get_precision** (self)
Getter for the precision matrix.

**Returns**

- **precision_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (self, X)
Computes the squared Mahalanobis distances of given observations.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- **dist** [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

**score** (self, X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

**Parameters**
X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.covariance.GraphicalLassoCV

• Sparse inverse covariance estimation
• Visualizing the stock market structure

7.5.5 sklearn.covariance.LedoitWolf

class sklearn.covariance.LedoitWolf (store_precision=True, assume_centered=False, block_size=1000)

LedoitWolf Estimator

Read more in the User Guide.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix
**precision_** [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

**shrinkage_** [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

**Notes**

The regularised covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features and shrinkage is given by the Ledoit and Wolf formula (see References)

**References**

**Examples**

```python
>>> import numpy as np
>>> from sklearn.covariance import LedoitWolf
>>> real_cov = np.array([[.4, .2],
...                        [.2, .8]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0],
...                                    cov=real_cov,
...                                    size=50)
>>> cov = LedoitWolf().fit(X)
>>> cov.covariance_
array([[0.4406..., 0.1616...],
       [0.1616..., 0.8022...]])
>>> cov.location_
array([ 0.0595..., -0.0075...])
```

**Methods**

- **error_norm**(self, comp_cov[, norm, scaling, ...]) Computes the Mean Squared Error between two covariance estimators.
- **fit**(self, X[, y]) Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.
- **get_params**(self[, deep]) Get parameters for this estimator.
- **get_precision**(self) Getter for the precision matrix.
- **mahalanobis**(self, X) Computes the squared Mahalanobis distances of given observations.
- **score**(self, X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.
- **set_params**(self, **params) Set the parameters of this estimator.
__init__ (self, store_precision=True, assume_centered=False, block_size=1000)
Initialize self. See help(type(self)) for accurate signature.

error_norm (self, comp_cov, norm='frobenius', scaling=True, squared=True)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.
norm [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \sqrt{\text{tr}(A^t.A)} - ‘spectral’: \sqrt{\max(\text{eigenvalues}(A^t.A))} where A is the error (comp_cov - self.covariance_).
scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (self, X, y=None)
Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y not used, present for API consistence purpose.

Returns
self [object]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

get_precision (self)
Getter for the precision matrix.

Returns
precision_ [array-like] The precision matrix associated to the current covariance object.

mahalanobis (self, X)
Computes the squared Mahalanobis distances of given observations.

Parameters
X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

score (self, X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.covariance.LedoitWolf

- Ledoit-Wolf vs OAS estimation
- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)

7.5.6 sklearn.covariance.MinCovDet

class sklearn.covariance.MinCovDet (store_precision=True, assume_centered=False, support_fraction=None, random_state=None)
Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a MinCovDet object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.

Read more in the User Guide.
Parameters

store_precision  [bool] Specify if the estimated precision is stored.

assume_centered  [bool] If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction  [float, 0 < support_fraction < 1] The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of support_fraction will be used within the algorithm: \[\frac{n_{\text{sample}} + n_{\text{features}} + 1}{2}\]

random_state  [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by \texttt{np.random}.

Attributes

raw_location_  [array-like, shape (n_features,)] The raw robust estimated location before correction and re-weighting.

raw_covariance_  [array-like, shape (n_features, n_features)] The raw robust estimated covariance before correction and re-weighting.

raw_support_  [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

location_  [array-like, shape (n_features,)] Estimated robust location

covariance_  [array-like, shape (n_features, n_features)] Estimated robust covariance matrix

precision_  [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_  [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

dist_  [array-like, shape (n_samples,)] Mahalanobis distances of the training set (on which \texttt{fit} is called) observations.

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import MinCovDet
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                        [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                              cov=real_cov,
...                              size=500)
```
```python
>>> cov = MinCovDet(random_state=0).fit(X)
>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])
>>> cov.location_
array([0.0813..., 0.0427...])
```

**Methods**

```python
__init__(self, store_precision=True, assume_centered=False, support_fraction=None, random_state=None)  
Initialize self. See help(type(self)) for accurate signature.
```

**`correct_covariance`** *(self, data)*

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

**Parameters**

- **data** [array-like, shape (n_samples, n_features)] The data matrix, with \( p \) features and \( n \) samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **covariance_corrected** [array-like, shape (n_features, n_features)] Corrected robust covariance estimate.

**References**

[RVD]

**`error_norm`** *(self, comp_cov, norm='frobenius', scaling=True, squared=True)*

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**
comp_cov  [array-like of shape (n_features, n_features)] The covariance to compare with.

norm  [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A))) where A is the error (comp_cov - self.covariance_).

scaling  [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared  [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit  (self, X, y=None)
Fits a Minimum Covariance Determinant with the FastMCD algorithm.

Parameters
X  [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y  not used, present for API consistence purpose.

Returns
self  [object]

get_params  (self, deep=True)
Get parameters for this estimator.

Parameters
deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params  [mapping of string to any] Parameter names mapped to their values.

get_precision  (self)
Getter for the precision matrix.

Returns
precision_  [array-like] The precision matrix associated to the current covariance object.

mahalanobis  (self, X)
Computes the squared Mahalanobis distances of given observations.

Parameters
X  [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns
dist  [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

reweight_covariance  (self, data)
Re-weight raw Minimum Covariance Determinant estimates.
Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

Parameters

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

location_reweighted [array-like, shape (n_features, )] Re-weighted robust location estimate.

covariance_reweighted [array-like, shape (n_features, n_features)] Re-weighted robust covariance estimate.

support_reweighted [array-like, type boolean, shape (n_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

References

[RVDriessen]

score (self, X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.covariance.MinCovDet

- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate
7.5.7 sklearn.covariance.OAS

**class sklearn.covariance.OAS(store_precision=True, assume_centered=False)**

Oracle Approximating Shrinkage Estimator

Read more in the User Guide.

The formula used here does not correspond to the one given in the article. In the original article, formula (23) states that 2/p is multiplied by Trace(cov*cov) in both the numerator and denominator, but this operation is omitted because for a large p, the value of 2/p is so small that it doesn’t affect the value of the estimator.

**Parameters**

- **store_precision** [bool, default=True] Specify if the estimated precision is stored.
- **assume_centered** [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

**Attributes**

- **covariance_** [array-like, shape (n_features, n_features)] Estimated covariance matrix.
- **precision_** [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
- **shrinkage_** [float, 0 <= shrinkage <= 1] coefficient in the convex combination used for the computation of the shrunk estimate.

**Notes**

The regularised covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features and shrinkage is given by the OAS formula (see References)

score(self, X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

set_params(self, **params) Set the parameters of this estimator.

__init__(self, store_precision=True, assume_centered=False)
Initialize self. See help(type(self)) for accurate signature.

error_norm(self, comp_cov, norm='frobenius', scaling=True, squared=True)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit(self, X, y=None)
Fits the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y not used, present for API consistence purpose.

Returns

self [object]

get_params(self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(self)
Getter for the precision matrix.

Returns
precision_ [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** *(self, X)*

Computes the squared Mahalanobis distances of given observations.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- **dist** [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

**score** *(self, X_test, y=None)*

Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

**Parameters**

- **X_test** [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).
- **y** not used, present for API consistence purpose.

**Returns**

- **res** [float] The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form *<component>__<parameter>* so that it’s possible to update each component of a nested object.

**Parameters**

- ****params [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**Examples using sklearn.covariance.OAS**

- *Ledoit-Wolf vs OAS estimation*
- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

**7.5.8 sklearn.covariance.ShrunkenCovariance**

class sklearn.covariance.ShrunkenCovariance *(store_precision=True, assume_centered=False, shrinkage=0.1)*

Covariance estimator with shrinkage

Read more in the *User Guide*.

**Parameters**

---

7.5. sklearn.covariance: Covariance Estimators 1655
store_precision  [boolean, default True] Specify if the estimated precision is stored

assume_centered  [boolean, default False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

shrinkage  [float, 0 <= shrinkage <= 1, default 0.1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Attributes

location_  [array-like, shape (n_features,)] Estimated location, i.e., the estimated mean.

covariance_  [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_  [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

Notes

The regularized covariance is given by:

$$ (1 - \text{shrinkage}) \cdot \text{cov} + \text{shrinkage} \cdot \mu \cdot \text{np.identity(n_features)} $$

where $\mu = \text{trace(cov)} / n_{\text{features}}$

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import ShrunkCovariance
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([[.8, .3], [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0], cov=real_cov, size=500)
>>> cov = ShrunkCovariance().fit(X)
>>> cov.covariance_
array([[0.7387..., 0.2536...],
        [0.2536..., 0.4110...]])
>>> cov.location_
array([0.0622..., 0.0193...])
```

**__init__** *(self, store_precision=True, assume_centered=False, shrinkage=0.1)*

Initialize self. See help(type(self)) for accurate signature.

**error_norm** *(self, comp_cov, norm='frobenius', scaling=True, squared=True)*

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \( \sqrt{\text{tr}(A^t.A)} \) - ‘spectral’: \( \sqrt{\text{max(eigenvalues}(A^t.A))} \) where \( A \) is the error \( \text{comp_cov} - \text{self.covariance}_\).  
- **scaling** [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

The Mean Squared Error (in the sense of the Frobenius norm) between **self** and **comp_cov** covariance estimators.

**fit** *(self, X, y=None)*

Fits the shrunk covariance model according to the given training data and parameters.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** not used, present for API consistence purpose.

**Returns**

**self** [object]

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get_precision** *(self)*

Getter for the precision matrix.

**Returns**

**precision_** [array-like] The precision matrix associated to the current covariance object.
mahalanobis(self, X)

Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

score(self, X_test, y=None)

Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.covariance.ShrunkCovariance

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)

**7.5.9 sklearn.covariance.empirical_covariance**

This function computes the Maximum likelihood covariance estimator. It takes two parameters:

- `X`: An array-like with shape (n_samples, n_features) indicating the data from which to compute the covariance estimate.
- `assume_centered`: A boolean indicating whether the data should be centered before computation.

The function returns an empirical covariance estimate (Maximum Likelihood Estimator).

**Examples using sklearn.covariance.empirical_covariance**

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

**7.5.10 sklearn.covariance.graphical_lasso**

This function computes an l1-penalized covariance estimator using the `graphical_lasso` method. It takes several parameters:

- `emp_cov`: An array-like with shape (n_samples, n_features) indicating the empirical covariance from which to compute the covariance estimate.
- `alpha`: A positive float indicating the regularization parameter for the covariance.
- `cov_init`: An optional array-like with shape (n_features, n_features) indicating the initial guess for the covariance.
- `mode`: A string indicating the Lasso solver to use: 'cd' for coordinate descent or 'lars' for LARS.
- `tol`, `enet_tol`, `max_iter`, `verbose`, `return_costs`, `return_n_iter`: Various optional parameters controlling the solver's behavior and output.

The function returns an estimated covariance matrix.

Read more in the User Guide.
verbose [boolean, optional] If verbose is True, the objective function and dual gap are printed at each iteration.

return_costs [boolean, optional] If return_costs is True, the objective function and dual gap at each iteration are returned.

es [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

covariance [2D ndarray, shape (n_features, n_features)] The estimated covariance matrix.

precision [2D ndarray, shape (n_features, n_features)] The estimated (sparse) precision matrix.

costs [list of (objective, dual_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if return_costs is True.

n_iter [int] Number of iterations. Returned only if return_n_iter is set to True.

See also:

GraphicalLasso, GraphicalLassoCV

Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R glasso package.

One possible difference with the glasso R package is that the diagonal coefficients are not penalized.

7.5.11 sklearn.covariance.ledoit_wolf

sklearn.covariance.ledoit_wolf(X, assume_centered=False, block_size=1000)

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the User Guide.

Parameters

X [array-like, shape (n_samples, n_features)] Data from which to compute the covariance estimate.

assume_centered [boolean, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

Returns

shrunk_cov [array-like, shape (n_features, n_features)] Shrunk covariance.

shrinkage [float] Coefficient in the convex combination used for the computation of the shrunk estimate.
Notes

The regularized (shrunk) covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity}(n\text{\_features})\]

where \(\mu = \text{trace}(\text{cov}) / n\text{\_features}\)

Examples using `sklearn.covariance.ledoit_wolf`

- Sparse inverse covariance estimation

7.5.12 `sklearn.covariance.oas`

`sklearn.covariance.oas(X, assume_centered=False)`

Estimate covariance with the Oracle Approximating Shrinkage algorithm.

Parameters

- `X` [array-like, shape (n_samples, n_features)] Data from which to compute the covariance estimate.
- `assume_centered` [boolean] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

Returns

- `shrunk_cov` [array-like, shape (n_features, n_features)] Shrunk covariance.
- `shrinkage` [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised (shrunk) covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity}(n\text{\_features})\]

where \(\mu = \text{trace}(\text{cov}) / n\text{\_features}\)

The formula we used to implement the OAS is slightly modified compared to the one given in the article. See `OAS` for more details.

7.5.13 `sklearn.covariance.shrunk_covariance`

`sklearn.covariance.shrunk_covariance(emp_cov, shrinkage=0.1)`

Calculates a covariance matrix shrunk on the diagonal

Read more in the `User Guide`.

Parameters

- `emp_cov` [array-like, shape (n_features, n_features)] Covariance matrix to be shrunk
- `shrinkage` [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Returns
shrunk_cov  [array-like]  Shrunk covariance.

Notes
The regularized (shrunk) covariance is given by:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

7.6 sklearn.cross_decomposition: Cross decomposition

User guide: See the Cross decomposition section for further details.

+---------------------------------+--------------------------------------------------+
| cross_decomposition.CCA           | CCA Canonical Correlation Analysis.               |
| cross_decomposition.PLSCanonical  | PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000]. |
| cross_decomposition.PLSSVD        | PLS regression                                    |
| cross_decomposition.PLSSVD([n_components,...]) | Partial Least Square SVD                            |

7.6.1 sklearn.cross_decomposition.CCA

class sklearn.cross_decomposition.CCA (n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)

CCA Canonical Correlation Analysis.
CCA inherits from PLS with mode="B" and deflation_mode="canonical".
Read more in the User Guide.

Parameters

- n_components [int, (default 2.)] number of components to keep.
- scale [boolean, (default True)] whether to scale the data?
- max_iter [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop
- tol [non-negative real, default 1e-06.] the tolerance used in the iterative algorithm
- copy [boolean] Whether the deflation be done on a copy. Let the default value to True unless you don’t care about side effects

Attributes

- x_weights_ [array, [p, n_components]] X block weights vectors.
- y_weights_ [array, [q, n_components]] Y block weights vectors.
- x_loadings_ [array, [p, n_components]] X block loadings vectors.
- y_loadings_ [array, [q, n_components]] Y block loadings vectors.
x_scores_  [array, [n_samples, n_components]] X scores.
y_scores_  [array, [n_samples, n_components]] Y scores.
x_rotations_  [array, [p, n_components]] X block to latents rotations.
y_rotations_  [array, [q, n_components]] Y block to latents rotations.
n_iter_  [array-like] Number of iterations of the NIPALS inner loop for each component.

See also:

PLSCanonical

PLSSVD

Notes

For each component k, find the weights u, v that maximizes max corr(Xk u, Yk v), such that |u| = |v| = 1

Note that it maximizes only the correlations between the scores.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score.

References

Examples

```python
>>> from sklearn.cross_decomposition import CCA
>>> X = [[1.0, 0.0, 1.0], [1.0, 0.0, 1.0], [2.0, 2.0, 2.0], [3.0, 5.0, 4.0]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> cca = CCA(n_components=1)
>>> cca.fit(X, Y)
CCA(n_components=1)
>>> X_c, Y_c = cca.transform(X, Y)
```

Methods

- `fit(self, X, Y)`: Fit model to data.
- `fit_transform(self, X[, y])`: Learn and apply the dimension reduction on the train data.
- `get_params(self[, deep])`: Get parameters for this estimator.
- `inverse_transform(self, X)`: Transform data back to its original space.
- `predict(self, X[, copy])`: Apply the dimension reduction learned on the train data.

__init__ (self, n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, Y)
Fit model to data.

Parameters
- X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform (self, X, y=None)
Learn and apply the dimension reduction on the train data.

Parameters
- X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns
- x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)
Transform data back to its original space.

Parameters
- X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns
- x_reconstructed [array-like of shape (n_samples, n_features)]
Notes

This transformation will only be exact if n_components=n_features

**predict**(self, X, copy=True)
Apply the dimension reduction learned on the train data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

**score**(self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred)**2).sum() and v is the total sum of squares ((y_true - y_true.mean())**2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

**set_params**(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**
**self** [object] Estimator instance.

**transform** *(self, X, Y=None, copy=True)*

Apply the dimension reduction learned on the train data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **Y** [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.
- **copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

**Returns**

- **x_scores** if Y is not given, (x_scores, y_scores) otherwise.

**Examples using sklearn.cross_decomposition.CCA**

- Multilabel classification
- Compare cross decomposition methods

### 7.6.2 sklearn.cross_decomposition.PLSCanonical

**class** *sklearn.cross_decomposition.PLSCanonical*(**n_components=2, scale=True, algorithm='nipals', max_iter=500, tol=1e-06, copy=True*)

PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].

This class inherits from PLS with mode="A" and deflation_mode="canonical", norm_y_weights=True and algorithm="nipals", but svd should provide similar results up to numerical errors.

Read more in the *User Guide*.

New in version 0.8.

**Parameters**

- **n_components** [int, (default 2)] Number of components to keep
- **scale** [boolean, (default True)] Option to scale data
- **algorithm** [string, "nipals" or "svd"] The algorithm used to estimate the weights. It will be called n_components times, i.e. once for each iteration of the outer loop.
- **max_iter** [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")
- **tol** [non-negative real, default 1e-06] the tolerance used in the iterative algorithm
- **copy** [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don’t care about side effect

**Attributes**

- **x_weights_** [array, shape = [p, n_components]] X block weights vectors.
- **y_weights_** [array, shape = [q, n_components]] Y block weights vectors.
- **x_loadings_** [array, shape = [p, n_components]] X block loadings vectors.
y_loadings_ [array, shape = [q, n_components]] Y block loadings vectors.

x_scores_ [array, shape = [n_samples, n_components]] X scores.

y_scores_ [array, shape = [n_samples, n_components]] Y scores.

x_rotations_ [array, shape = [p, n_components]] X block to latents rotations.

y_rotations_ [array, shape = [q, n_components]] Y block to latents rotations.

n_iter_ [array-like] Number of iterations of the NIPALS inner loop for each component. Not useful if the algorithm provided is "svd".

See also:

CCA
PLSSVD

Notes

Matrices:

T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings_

Are computed such that:

\[ X = T P.T + \text{Err} \quad \text{and} \quad Y = U Q.T + \text{Err} \]

\[ T[:, k] = X_k W[:, k] \quad \text{for} \quad k \in \text{range}(n\text{-}components) \]

\[ U[:, k] = Y_k C[:, k] \quad \text{for} \quad k \in \text{range}(n\text{-}components) \]

x_rotations_ = W (P.T W)^{-1}

y_rotations_ = C (Q.T C)^{-1}

where Xk and Yk are residual matrices at iteration k.

Slides explaining PLS

For each component k, find weights u, v that optimize:

\[ \max \, \text{corr}(X_k u, Y_k v) \times \text{std}(X_k u) \times \text{std}(Y_k u), \text{ such that } ||u|| = ||v|| = 1 \]

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score. This performs a canonical symmetric version of the PLS regression. But slightly different than the CCA. This is mostly used for modeling.

This implementation provides the same results that the “plspm” package provided in the R language (R-project), using the function plsca(X, Y). Results are equal or collinear with the function pls(..., mode = "canonical") of the “mixOmics” package. The difference relies in the fact that mixOmics implementation does not exactly implement the Wold algorithm since it does not normalize y_weights to one.
References

Examples

```python
>>> from sklearn.cross_decomposition import PLSCanonical
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> plsca = PLSCanonical(n_components=2)
>>> plsca.fit(X, Y)
PLSCanonical()
>>> X_c, Y_c = plsca.transform(X, Y)
```

Methods

- `fit(self, X, Y)` Fit model to data.
- `fit_transform(self, X[, y])` Learn and apply the dimension reduction on the train data.
- `get_params(self[, deep])` Get parameters for this estimator.
- `inverse_transform(self, X)` Transform data back to its original space.
- `predict(self, X[, copy])` Apply the dimension reduction learned on the train data.
- `score(self, X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X[, Y , copy])` Apply the dimension reduction learned on the train data.

```
__init__(self, n_components=2, scale=True, algorithm='nipals', max_iter=500, tol=1e-06, copy=True)
```

Initialize self. See help(type(self)) for accurate signature.

- `fit(self, X, Y)` Fit model to data.
  - **Parameters**
    - `X` [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
    - `Y` [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

- `fit_transform(self, X, y=None)` Learn and apply the dimension reduction on the train data.
  - **Parameters**
    - `X` [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)
Transform data back to its original space.

Parameters

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns

x_reconstructed [array-like of shape (n_samples, n_features)]

Notes

This transformation will only be exact if n_components=n_features

predict (self, X, copy=True)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score (self, X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares ($(y_{true} - y_{pred})^2$).sum() and $v$ is the total sum of squares ($(y_{true} - y_{true.mean})^2$).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X, Y=None, copy=True)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using sklearn.cross_decomposition.PLSCanonical

- Compare cross decomposition methods

7.6.3 sklearn.cross_decomposition.PLSRegression

class sklearn.cross_decomposition.PLSRegression (n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)
PLSRegression implements the PLS 2 blocks regression known as PLS2 or PLS1 in case of one dimensional response. This class inherits from _PLS with mode="A", deflation_mode="regression", norm_y_weights=False and algorithm="nipals".

Read more in the User Guide.

New in version 0.8.

Parameters

- **n_components** [int, (default 2)] Number of components to keep.
- **scale** [boolean, (default True)] whether to scale the data
- **max_iter** [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")
- **tol** [non-negative real] Tolerance used in the iterative algorithm default 1e-06.
- **copy** [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don’t care about side effect

Attributes

- **x_weights_** [array, [p, n_components]] X block weights vectors.
- **y_weights_** [array, [q, n_components]] Y block weights vectors.
- **x_loadings_** [array, [p, n_components]] X block loadings vectors.
- **y_loadings_** [array, [q, n_components]] Y block loadings vectors.
- **x_scores_** [array, [n_samples, n_components]] X scores.
- **y_scores_** [array, [n_samples, n_components]] Y scores.
- **x_rotations_** [array, [p, n_components]] X block to latents rotations.
- **y_rotations_** [array, [q, n_components]] Y block to latents rotations.
- **coef_** [array, [p, q]] The coefficients of the linear model: \( Y = X \ coefficient + Err \)
- **n_iter_** [array-like] Number of iterations of the NIPALS inner loop for each component.

Notes

Matrices:

- \( T : x_{\text{scores}} \)
- \( U : y_{\text{scores}} \)
- \( W : x_{\text{weights}} \)
- \( C : y_{\text{weights}} \)
- \( P : x_{\text{loadings}} \)
- \( Q : y_{\text{loadings}} \)

Are computed such that:

\[
X = T P.T + Err \ \ \ \text{and} \ \ \ Y = U Q.T + Err \\
T[:, k] = X_k W[:, k] \ \ \ \text{for} \ \ k \ \ \text{in} \ \ \text{range}(n_{\text{components}}) \\
U[:, k] = Y_k C[:, k] \ \ \ \text{for} \ \ k \ \ \text{in} \ \ \text{range}(n_{\text{components}}) \\
x_{\text{rotations}}_ = W (P.T W)^{-1} \\
y_{\text{rotations}}_ = C (Q.T C)^{-1}
\]
where \( X_k \) and \( Y_k \) are residual matrices at iteration \( k \).

**Slides explaining PLS**

For each component \( k \), find weights \( u, v \) that optimizes:

\[
\max \text{corr}(X_k u, Y_k v) \cdot \frac{\text{std}(X_k u)}{\text{std}(Y_k u)}, \text{such that } |u| = 1
\]

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of \( X \) (\( X_{k+1} \)) block is obtained by the deflation on the current \( X \) score: \( x_{\text{score}} \).

The residual matrix of \( Y \) (\( Y_{k+1} \)) block is obtained by deflation on the current \( X \) score. This performs the PLS regression known as PLS2. This mode is prediction oriented.

This implementation provides the same results that 3 PLS packages provided in the R language (R-project):

- “mixOmics” with function pls(X, Y, mode = “regression”)
- “plspm ” with function plsreg2(X, Y)
- “pls” with function oscorespls.fit(X, Y)

**References**

**Examples**

```python
>>> from sklearn.cross_decomposition import PLSRegression
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> pls2 = PLSRegression(n_components=2)
>>> pls2.fit(X, Y)
PLSRegression()
>>> Y_pred = pls2.predict(X)
```

__init__(self, n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)
Initialize self. See help(type(self)) for accurate signature.

fit(self, X, Y)
Fit model to data.

Parameters
X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform(self, X, y=None)
Learn and apply the dimension reduction on the train data.

Parameters
X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns
x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(self, X)
Transform data back to its original space.

Parameters
X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns
x_reconstructed [array-like of shape (n_samples, n_features)]

Notes
This transformation will only be exact if n_components=n_features

predict(self, X, copy=True)
Apply the dimension reduction learned on the train data.

Parameters
X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score (self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X, Y=None, copy=True)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.
copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using sklearn.cross_decomposition.PLSRegression

• Compare cross decomposition methods

7.6.4 sklearn.cross_decomposition.PLSSVD

class sklearn.cross_decomposition.PLSSVD(n_components=2, scale=True, copy=True)
Partial Least Square SVD

Simply perform a svd on the crosscovariance matrix: X′Y There are no iterative deflation here.

Read more in the User Guide.

New in version 0.8.

Parameters

n_components [int, default 2] Number of components to keep.

scale [boolean, default True] Whether to scale X and Y.

copy [boolean, default True] Whether to copy X and Y, or perform in-place computations.

Attributes

x_weights_ [array, [p, n_components]] X block weights vectors.

y_weights_ [array, [q, n_components]] Y block weights vectors.

x_scores_ [array, [n_samples, n_components]] X scores.

y_scores_ [array, [n_samples, n_components]] Y scores.

__init__(self, n_components=2, scale=True, copy=True)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, Y)

Fit model to data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform (self, X, y=None)

Learn and apply the dimension reduction on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform** (self, X, Y=None)

Apply the dimension reduction learned on the train data.

**Parameters**

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

## 7.7 sklearn.datasets: Datasets

The `sklearn.datasets` module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

**User guide:** See the `Dataset loading utilities` section for further details.

**sklearn.datasets.clear_data_home**

Delete all the content of the data home cache.

**Parameters**

- `data_home` [str | None] The path to scikit-learn data dir.

**sklearn.datasets.dump_svmlight_file**

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

**Parameters**

- `X` [array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like, sparse matrix], shape = [n_samples, n_labels] Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.
- `f` [string or file-like in binary mode] If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.
- `zero_based` [boolean, optional] Whether column indices should be written zero-based (True) or one-based (False).
- `comment` [string, optional] Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.
- `query_id` [array-like of shape (n_samples,)] Array containing pairwise preference constraints (qid in svmlight format).
**multilabel** [boolean, optional] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

New in version 0.17: parameter `multilabel` to support multilabel datasets.

**Examples using sklearn.datasets.dump_svmlight_file**

- Libsvm GUI

**sklearn.datasets.fetch_20newsgroups**

```python
sklearn.datasets.fetch_20newsgroups(data_home=None, subset='train', categories=None, shuffle=True, random_state=42, remove=(), download_if_missing=True, return_X_y=False)
```

Load the filenames and data from the 20 newsgroups dataset (classification).

Download it if necessary.

<table>
<thead>
<tr>
<th>Classes</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples total</td>
<td>18846</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>1</td>
</tr>
<tr>
<td>Features</td>
<td>text</td>
</tr>
</tbody>
</table>

Read more in the *User Guide*.

**Parameters**

- **data_home** [optional, default: None] Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **subset** ['train' or 'test', 'all', optional] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.

- **categories** [None or collection of string or unicode] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

- **shuffle** [bool, optional] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

- **random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

- **remove** [tuple] May contain any subset of (‘headers’, ‘footers’, ‘quotes’). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

  - ‘headers’ removes newsgroup headers, ‘footers’ removes blocks at the ends of posts that look like signatures, and ‘quotes’ removes lines that appear to be quoting another post.

  - ‘headers’ follows an exact standard; the other filters are not always correct.

- **download_if_missing** [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

- **return_X_y** [bool, default=False.] If True, returns `(data.data, data.target)` instead of a Bunch object.
New in version 0.22.

Returns

**bunch** [Bunch object with the following attribute:]

- data: list, length [n_samples]
- target: array, shape [n_samples]
- filenames: list, length [n_samples]
- DESCRI: a description of the dataset.
- target_names: a list of categories of the returned data, length [n_classes]. This depends on the categories parameter.

(data, target) [tuple if return_X_y=True] New in version 0.22.

Examples using sklearn.datasets.fetch_20newsgroups

- Sample pipeline for text feature extraction and evaluation

sklearn.datasets.fetch_20newsgroups_vectorized

```
sklearn.datasets.fetch_20newsgroups_vectorized(subset='train', remove=(),
                                                data_home=None, download_if_missing=True,
                                                return_X_y=False, normalize=True)
```

Load the 20 newsgroups dataset and vectorize it into token counts (classification).

Download it if necessary.

This is a convenience function; the transformation is done using the default settings for sklearn.feature_extraction.text.CountVectorizer. For more advanced usage (stopword filtering, n-gram extraction, etc.), combine fetch_20newsgroups with a custom sklearn.feature_extraction.text.CountVectorizer, sklearn.feature_extraction.text.HashingVectorizer, or sklearn.feature_extraction.text.TfidfTransformer or sklearn.feature_extraction.text.TfidfVectorizer.

The resulting counts are normalized using sklearn.preprocessing.normalize unless normalize is set to False.

Read more in the User Guide.

Parameters

- **subset** ['train' or 'test', 'all', optional] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.

- **remove** [tuple] May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.
headers’ removes newsgroup headers, ‘footers’ removes blocks at the ends of posts that look like signatures, and ‘quotes’ removes lines that appear to be quoting another post.

**data_home** [optional, default: None] Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

**download_if_missing** [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

**return_X_y** [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.20.

**normalize** [bool, default=True] If True, normalizes each document’s feature vector to unit norm using sklearn.preprocessing.normalize.

New in version 0.22.

Returns

**bunch** [Bunch object with the following attribute:]

- bunch.data: sparse matrix, shape [n_samples, n_features]
- bunch.target: array, shape [n_samples]
- bunch.target_names: a list of categories of the returned data, length [n_classes].
- bunch.DESCR: a description of the dataset.

(data, target) [tuple if return_X_y is True] New in version 0.20.

**Examples using sklearn.datasets.fetch_20newsgroups_vectorized**

- The Johnson-Lindenstrauss bound for embedding with random projections
- Model Complexity Influence
- Multiclass sparse logistic regression on 20newsgroups

**sklearn.datasets.fetch_california_housing**

sklearn.datasets.fetch_california_housing(data_home=None, download_if_missing=True, return_X_y=False)

Load the California housing dataset (regression).

<table>

</table>

Read more in the User Guide.

**Parameters**

- **data_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **download_if_missing** [optional, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
return_X_y [boolean, default=False] If True, returns (data.data, data.target) instead of a Bunch object.
New in version 0.20.

Returns

dataset [dict-like object with the following attributes:]
dataset.data [ndarray, shape [20640, 8]] Each row corresponding to the 8 feature values in order.
dataset.target [numpy array of shape (20640,)] Each value corresponds to the average house value in units of 100,000.
dataset.feature_names [array of length 8] Array of ordered feature names used in the dataset.
dataset.DESCR [string] Description of the California housing dataset.
(data, target) [tuple if return_X_y is True] New in version 0.20.

Notes

This dataset consists of 20,640 samples and 9 features.

Examples using sklearn.datasets.fetch_california_housing

• Partial Dependence Plots
• Imputing missing values with variants of IterativeImputer
• Compare the effect of different scalers on data with outliers

sklearn.datasets.fetch_covtype

sklearn.datasets.fetch_covtype(data_home=None, download_if_missing=True, random_state=None, shuffle=False, return_X_y=False)

Load the covtype dataset (classification).
Download it if necessary.

<table>

Read more in the User Guide.

Parameters

data_home [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

download_if_missing [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.
shuffle  [bool, default=False] Whether to shuffle dataset.

return_X_y  [boolean, default=False.] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.20.

Returns

dataset  [dict-like object with the following attributes:]

dataset.data  [numpy array of shape (581012, 54)] Each row corresponds to the 54 features in the dataset.

dataset.target  [numpy array of shape (581012,)] Each value corresponds to one of the 7 forest covertypes with values ranging between 1 to 7.

dataset.DESCR  [string] Description of the forest covertype dataset.

(data, target)  [tuple if return_X_y is True] New in version 0.20.

7.7. sklearn.datasets: Datasets

sklearn.datasets.fetch_kddcup99

sklearn.datasets.fetch_kddcup99 (subset=None, data_home=None, shuffle=False, random_state=None, percent10=True, download_if_missing=True, return_X_y=False)

Load the kddcup99 dataset (classification).

Download it if necessary.

<table>

Read more in the User Guide.

New in version 0.18.

Parameters

data_home  [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders. .. versionadded:: 0.19

shuffle  [bool, default=False] Whether to shuffle dataset.

random_state  [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and for selection of abnormal samples if subset='SA'. Pass an int for reproducible output across multiple function calls. See Glossary.

percent10  [bool, default=True] Whether to load only 10 percent of the data.

download_if_missing  [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y  [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.
New in version 0.20.

Returns

data  [Bunch]

Dictionary-like object, the interesting attributes are:

- ‘data’, the data to learn.
- ‘target’, the regression target for each sample.
- ‘DESCR’, a description of the dataset.

(data, target)  [tuple if return_X_y is True] New in version 0.20.

sklearn.datasets.fetch_lfw_pairs

sklearn.datasets.fetch_lfw_pairs (subset='train', data_home=None, funneled=True, resize=0.5, color=False, slice_=(slice(70, 195, None), slice(78, 172, None)), download_if_missing=True)

Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).

Download it if necessary.

<table>
<thead>
<tr>
<th>Classes</th>
<th>5749</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples total</td>
<td>13233</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>5828</td>
</tr>
<tr>
<td>Features</td>
<td>real, between 0 and 255</td>
</tr>
</tbody>
</table>

In the official README.txt this task is described as the “Restricted” task. As I am not sure as to implement the “Unrestricted” variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Read more in the User Guide.

Parameters

subset  [optional, default: ‘train’] Select the dataset to load: ‘train’ for the development training set, ‘test’ for the development test set, and ‘10_folds’ for the official evaluation set that is meant to be used with a 10-folds cross validation.

data_home  [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

funneled  [boolean, optional, default: True] Download and use the funneled variant of the dataset.

resize  [float, optional, default 0.5] Ratio used to resize the each face picture.

color  [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

slice_  [optional] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background

download_if_missing  [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
Returns

The data is returned as a Bunch object with the following attributes:

- **data** [numpy array of shape (2200, 5828)]. Shape depends on `subset`. Each row corresponds to 2 ravel’d face images of original size 62 x 47 pixels. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

- **pairs** [numpy array of shape (2200, 2, 62, 47)]. Shape depends on `subset`. Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

- **target** [numpy array of shape (2200,)]. Shape depends on `subset`. Labels associated to each pair of images. The two label values being different persons or the same person.

DESCR [string] Description of the Labeled Faces in the Wild (LFW) dataset.

```python
sklearn.datasets.fetch_lfw_people
data_home=None, funneled=True, resize=0.5,
min_faces_per_person=0, color=False, slice_=(slice(70,
195, None), slice(78, 172, None)),
download_if_missing=True, return_X_y=False)
```

Load the Labeled Faces in the Wild (LFW) people dataset (classification).

Download it if necessary.

<table>
<thead>

<tr>
<td>Dimensionality</td>
<td>5828</td>
</tr>
<tr>
<td>Features</td>
<td>real, between 0 and 255</td>
</tr>
</tbody>
</table>

Read more in the *User Guide*.

Parameters

- **data_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **funneled** [boolean, optional, default: True] Download and use the funneled variant of the dataset.

- **resize** [float, optional, default 0.5] Ratio used to resize the each face picture.

- **min_faces_per_person** [int, optional, default None] The extracted dataset will only retain pictures of people that have at least `min_faces_per_person` different pictures.

- **color** [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

- **slice_** [optional] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background.

- **download_if_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
return_X_y [boolean, default=False] If True, returns (dataset.data, dataset.target) instead of a Bunch object. See below for more information about the dataset.data and dataset.target object.

New in version 0.20.

Returns

dataset [dict-like object with the following attributes:]

dataset.data [numpy array of shape (13233, 2914)] Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the slice_ or resize parameters will change the shape of the output.

dataset.images [numpy array of shape (13233, 62, 47)] Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the slice_ or resize parameters will change the shape of the output.

dataset.target [numpy array of shape (13233,)] Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.

dataset.DESCR [string] Description of the Labeled Faces in the Wild (LFW) dataset.

(data, target) [tuple if return_X_y is True] New in version 0.20.

Examples using sklearn.datasets.fetch_lfw_people

- Faces recognition example using eigenfaces and SVMs

sklearn.datasets.fetch_olivetti_faces

sklearn.datasets.fetch_olivetti_faces (data_home=None, shuffle=False, random_state=0, download_if_missing=True, return_X_y=False)

Load the Olivetti faces data-set from AT&T (classification).

Download it if necessary.

<table>
<thead>
<tr>
<th>Classes</th>
<th>40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples total</td>
<td>400</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>4096</td>

<tr>
<td>Features</td>
<td>real, between 0 and 1</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

shuffle [boolean, optional] If True the order of the dataset is shuffled to avoid having images of the same person grouped.

random_state [int, RandomState instance or None (default=0)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

download_if_missing [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
**return_X_y** [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.22.

**Returns**

**bunch** [Bunch object with the following attributes:]

- **data**: ndarray, shape (400, 4096). Each row corresponds to a ravelled face image of original size 64 x 64 pixels.
- **images**: ndarray, shape (400, 64, 64). Each row is a face image corresponding to one of the 40 subjects of the dataset.
- **target**: ndarray, shape (400,). Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.
- **DESCR**: string. Description of the modified Olivetti Faces Dataset.

*(data, target)* [tuple if return_X_y=True] New in version 0.22.

**Examples using sklearn.datasets.fetch_olivetti_faces**

- Face completion with a multi-output estimators
- Online learning of a dictionary of parts of faces
- Faces dataset decompositions
- Pixel importances with a parallel forest of trees

**sklearn.datasets.fetch_openml**

**sklearn.datasets.fetch_openml** *(name=None, version=’active’, data_id=None, data_home=None, target_column=’default-target’, cache=True, return_X_y=False, as_frame=False)*

Fetch dataset from openml by name or dataset id.

Datasets are uniquely identified by either an integer ID or by a combination of name and version (i.e. there might be multiple versions of the ‘iris’ dataset). Please give either name or data_id (not both). In case a name is given, a version can also be provided.

Read more in the User Guide.

**Note:** EXPERIMENTAL

The API is experimental (particularly the return value structure), and might have small backward-incompatible changes in future releases.

**Parameters**

- **name** [str or None] String identifier of the dataset. Note that OpenML can have multiple datasets with the same name.

- **version** [integer or ‘active’, default=‘active’] Version of the dataset. Can only be provided if also name is given. If ‘active’ the oldest version that’s still active is used. Since there may be more than one active version of a dataset, and those versions may fundamentally be different from one another, setting an exact version is highly recommended.
**data_id** [int or None] OpenML ID of the dataset. The most specific way of retrieving a dataset. If `data_id` is not given, name (and potential version) are used to obtain a dataset.

**data_home** [string or None, default None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

**target_column** [string, list or None, default ‘default-target’] Specify the column name in the data to use as target. If ‘default-target’, the standard target column a stored on the server is used. If None, all columns are returned as data and the target is None. If list (of strings), all columns with these names are returned as multi-target (Note: not all scikit-learn classifiers can handle all types of multi-output combinations)

**cache** [boolean, default=True] Whether to cache downloaded datasets using joblib.

**return_X_y** [boolean, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` objects.

**as_frame** [boolean, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of `target_column`. The Bunch will contain a `frame` attribute with the target and the data. If `return_X_y` is True, then `(data, target)` will be pandas DataFrames or Series as describe above.

**Returns**

**data** [Bunch] Dictionary-like object, with attributes:

- **data** [np.array, scipy.sparse.csr_matrix of floats, or pandas DataFrame] The feature matrix. Categorical features are encoded as ordinals.
- **target** [np.array, pandas Series or DataFrame] The regression target or classification labels, if applicable. Dtype is float if numeric, and object if categorical. If `as_frame` is True, `target` is a pandas object.
- **DESCR** [str] The full description of the dataset
- **feature_names** [list] The names of the dataset columns
- **target_names** [list] The names of the target columns
- **categories** [dict or None] Maps each categorical feature name to a list of values, such that the value encoded as `i` is `ith` in the list. If `as_frame` is True, this is None.
- **details** [dict] More metadata from OpenML
- **frame** [pandas DataFrame] Only present when `as_frame=True`. DataFrame with `data` and `target`.

**Note:** EXPERIMENTAL

This interface is experimental and subsequent releases may change attributes without notice (although there should only be minor changes to `data` and `target`).

Missing values in the ‘data’ are represented as NaN’s. Missing values in ‘target’ are represented as NaN’s (numerical target) or None (categorical target)
Examples using `sklearn.datasets.fetch_openml`

- Approximate nearest neighbors in TSNE

`sklearn.datasets.fetch_rcv1`

```python
sklearn.datasets.fetch_rcv1(data_home=None, subset='all', download_if_missing=True, random_state=None, shuffle=False, return_X_y=False)
```

Load the RCV1 multilabel dataset (classification).

Download it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

New in version 0.17.

Parameters

- **data_home** [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **subset** [string, ‘train’, ‘test’, or ‘all’, default=’all’] Select the dataset to load: ‘train’ for the training set (23149 samples), ‘test’ for the test set (781265 samples), ‘all’ for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

- **download_if_missing** [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

- **random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

- **shuffle** [bool, default=False] Whether to shuffle dataset.

- **return_X_y** [boolean, default=False.] If True, returns `(dataset.data, dataset.target)` instead of a Bunch object. See below for more information about the dataset.data and dataset.target object.

Returns

- **dataset** [dict-like object with the following attributes:]

  - **dataset.data** [scipy csr array, dtype np.float64, shape (804414, 47236)] The array has 0.16% of non zero values.

  - **dataset.target** [scipy csr array, dtype np.uint8, shape (804414, 103)] Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values.

  - **dataset.sample_id** [numpy array, dtype np.uint32, shape (804414,)] Identification number of each sample, as ordered in dataset.data.
dataset.target_names  [ndarray, dtype object, length (103)] Names of each target (RCV1 topics), as ordered in dataset.target.
dataset.DESCR  [string] Description of the RCV1 dataset.
(data, target)  [tuple if return_X_y is True] New in version 0.20.

sklearn.datasets.fetch_species_distributions

sklearn.datasets.fetch_species_distributions(data_home=None, download_if_missing=True)

Loader for species distribution dataset from Phillips et. al. (2006)
Read more in the User Guide.

Parameters

data_home  [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
download_if_missing  [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

The data is returned as a Bunch object with the following attributes:

coverages  [array, shape = [14, 1592, 1212]] These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.
train  [record array, shape = (1624,)] The training points for the data. Each point has three fields:
• train[‘species’] is the species name
• train[‘dd long’] is the longitude, in degrees
• train[‘dd lat’] is the latitude, in degrees
test  [record array, shape = (620,)] The test points for the data. Same format as the training data.
Nx, Ny  [integers] The number of longitudes (x) and latitudes (y) in the grid
x_left_lower_corner, y_left_lower_corner  [floats] The (x,y) position of the lower-left corner, in degrees
grid_size  [float] The spacing between points of the grid, in degrees

Notes

This dataset represents the geographic distribution of species. The dataset is provided by Phillips et. al. (2006).
The two species are:
• “Bradypus variegatus”, the Brown-throated Sloth.
• “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.
• For an example of using this dataset with scikit-learn, see examples/applications/plot_species_distribution_modeling.py.
References

Examples using `sklearn.datasets.fetch_species_distributions`

- Species distribution modeling
- Kernel Density Estimate of Species Distributions

`sklearn.datasets.get_data_home`

`sklearn.datasets.get_data_home(data_home=None)`

Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named ‘scikit_learn_data’ in the user home folder.

Alternatively, it can be set by the ‘SCIKIT_LEARN_DATA’ environment variable or programmatically by giving an explicit folder path. The ‘~’ symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

Parameters

- `data_home` [str | None] The path to scikit-learn data dir.

Examples using `sklearn.datasets.get_data_home`

- Out-of-core classification of text documents

`sklearn.datasets.load_boston`

`sklearn.datasets.load_boston(return_X_y=False)`

Load and return the boston house-prices dataset (regression).

Read more in the User Guide.

Parameters

- `return_X_y` [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns
**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the regression targets, ‘DESCR’, the full description of the dataset, and ‘filename’, the physical location of boston csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

**Notes**

Changed in version 0.20: Fixed a wrong data point at [445, 0].

**Examples**

```python
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> print(X.shape)
(506, 13)
```

**Examples using sklearn.datasets.load_boston**

- Advanced Plotting With Partial Dependence
- Plot individual and voting regression predictions
- Gradient Boosting regression
- Combine predictors using stacking
- Outlier detection on a real data set
- Model Complexity Influence
- Feature selection using SelectFromModel and LassoCV
- Imputing missing values before building an estimator
- Plotting Cross-Validated Predictions
- Effect of transforming the targets in regression model

**sklearn.datasets.load_breast_cancer**

`sklearn.datasets.load_breast_cancer(return_X_y=False)`

Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

**Parameters**
return_X_y [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘target_names’, the meaning of the labels, ‘feature_names’, the meaning of the features, and ‘DESCR’, the full description of the dataset, ‘filename’, the physical location of breast cancer csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is downloaded from:
https://goo.gl/U2Uwz2

Examples

Let’s say you are interested in the samples 10, 50, and 85, and want to know their class name.

```python
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

Examples using sklearn.datasets.load_breast_cancer

- Post pruning decision trees with cost complexity pruning
- Permutation Importance with Multicollinear or Correlated Features

sklearn.datasets.load_diabetes

sklearn.datasets.load_diabetes (return_X_y=False)

Load and return the diabetes dataset (regression).

| Samples total  | 442  |
| Dimensionality | 10   |
| Features       | real, -2 < x < 2 |
| Targets        | integer 25 - 346 |

Read more in the User Guide.

Parameters

return_X_y [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns
data [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the regression target for each sample, ‘data_filename’, the physical location of diabetes data csv dataset, and ‘target_filename’, the physical location of diabetes targets csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

Examples using sklearn.datasets.load_diabetes

- Lasso path using LARS
- Linear Regression Example
- Sparsity Example: Fitting only features 1 and 2
- Lasso and Elastic Net
- Lasso model selection: Cross-Validation / AIC / BIC
- Imputing missing values before building an estimator
- Cross-validation on diabetes Dataset Exercise

sklearn.datasets.load_digits

sklearn.datasets.load_digits (n_class=10, return_X_y=False)
Load and return the digits dataset (classification).
Each datapoint is a 8x8 image of a digit.

<table>
<thead>
<tr>
<th>Classes</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples per class</td>
<td>~180</td>
</tr>
<tr>
<td>Samples total</td>
<td>1797</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>64</td>
</tr>
<tr>
<td>Features</td>
<td>integers 0-16</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

- n_class [integer, between 0 and 10, optional (default=10)] The number of classes to return.
- return_X_y [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns

- data [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘images’, the images corresponding to each sample, ‘target’, the classification labels for each sample, ‘target_names’, the meaning of the labels, and ‘DESCR’, the full description of the dataset.

(data, target) [tuple if return_X_y is True] New in version 0.18.

This is a copy of the test set of the UCI ML hand-written digits dataset
Examples

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_digits
digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```

Examples using `sklearn.datasets.load_digits`

- The Johnson-Lindenstrauss bound for embedding with random projections
- Explicit feature map approximation for RBF kernels
- Recognizing hand-written digits
- Feature agglomeration
- Various Agglomerative Clustering on a 2D embedding of digits
- A demo of K-Means clustering on the handwritten digits data
- The Digit Dataset
- Early stopping of Gradient Boosting
- Recursive feature elimination
- Comparing various online solvers
- L1 Penalty and Sparsity in Logistic Regression
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…
- Plotting Validation Curves
- Parameter estimation using grid search with cross-validation
- Comparing randomized search and grid search for hyperparameter estimation
- Balance model complexity and cross-validated score
- Plotting Learning Curves
- Kernel Density Estimation
- Caching nearest neighbors
- Dimensionality Reduction with Neighborhood Components Analysis
- Restricted Boltzmann Machine features for digit classification
- Compare Stochastic learning strategies for MLPClassifier
- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
sklearn.datasets.load_files

sklearn.datasets.load_files(container_path, description=None, categories=None, load_content=True, shuffle=True, encoding=None, decode_error='strict', random_state=0)

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

```
container_folder/
  category_1_folder/ file_1.txt file_2.txt ... file_42.txt
  category_2_folder/ file_43.txt file_44.txt ...
```

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if load_content is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the \texttt{sklearn.feature_extraction.text} module to build a feature extraction transformer that suits your problem.

If you set load_content=True, you should also specify the encoding of the text using the ‘encoding’ parameter. For many modern text files, ‘utf-8’ will be the correct encoding. If you leave encoding equal to None, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in \texttt{text}.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the User Guide.

Parameters

- **container_path** [string or unicode] Path to the main folder holding one subfolder per category
- **description** [string or unicode, optional (default=None)] A paragraph describing the characteristic of the dataset: its source, reference, etc.
- **categories** [A collection of strings or None, optional (default=None)] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).
- **load_content** [boolean, optional (default=True)] Whether to load or not the content of the different files. If true a ‘data’ attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.
- **shuffle** [bool, optional (default=True)] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.
- **encoding** [string or None (default is None)] If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if load_content is True.
- **decode_error** [‘strict’, ‘ignore’, ‘replace’], optional] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. Passed as keyword argument ‘errors’ to bytes.decode.
random_state [int, RandomState instance or None (default=0)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: either data, the raw text data to learn, or 'filenames', the files holding it, 'target', the classification labels (integer index), 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

sklearn.datasets.load_iris

sklearn.datasets.load_iris (return_X_y=False)

Load and return the iris dataset (classification).

The iris dataset is a classic and very easy multi-class classification dataset.

<table>
<thead>
<tr>
<th>Classes</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples per class</td>

<tr>
<td>Features</td>
<td>real, positive</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

return_X_y [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘target_names’, the meaning of the labels, ‘feature_names’, the meaning of the features, ‘DESCR’, the full description of the dataset, ‘filename’, the physical location of iris csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

Notes

Changed in version 0.20: Fixed two wrong data points according to Fisher’s paper. The new version is the same as in R, but not as in the UCI Machine Learning Repository.

Examples

Let’s say you are interested in the samples 10, 25, and 50, and want to know their class name.

```bash
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
array([0, 0, 1])
>>> list(data.target_names)
['setosa', 'versicolor', 'virginica']
```
Examples using `sklearn.datasets.load_iris`

- Plot classification probability
- Plot Hierarchical Clustering Dendrogram
- K-means Clustering
- The Iris Dataset
- Plot the decision surface of a decision tree on the iris dataset
- Understanding the decision tree structure
- PCA example with Iris Data-set
- Incremental PCA
- Comparison of LDA and PCA 2D projection of Iris dataset
- Plot the decision boundaries of a VotingClassifier
- Early stopping of Gradient Boosting
- Plot the decision surfaces of ensembles of trees on the iris dataset
- Test with permutations the significance of a classification score
- Univariate Feature Selection
- GMM covariances
- Gaussian process classification (GPC) on iris dataset
- Regularization path of L1- Logistic Regression
- Logistic Regression 3-class Classifier
- Plot multi-class SGD on the iris dataset

- SVM with custom kernel
- SVM-Anova: SVM with univariate feature selection
- Plot different SVM classifiers in the iris dataset
- RBF SVM parameters
• SVM Exercise

**sklearn.datasets.load_linnerud**

`sklearn.datasets.load_linnerud(return_X_y=False)`

Load and return the linnerud dataset (multivariate regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>3 (for both data and target)</td>
</tr>
<tr>
<td>Features</td>
<td>integer</td>
</tr>
<tr>
<td>Targets</td>
<td>integer</td>
</tr>
</tbody>
</table>

Read more in the *User Guide*.

**Parameters**

- `return_X_y` [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

  New in version 0.18.

**Returns**

- `data` [Bunch] Dictionary-like object, the interesting attributes are: `data` and `target`, the two multivariate datasets, with `data` corresponding to the exercise and `target` corresponding to the physiological measurements, as well as `feature_names` and `target_names`. In addition, you will also have access to `data_filename`, the physical location of linnerud data csv dataset, and `target_filename`, the physical location of linnerud targets csv datataset (added in version 0.20).

  `(data, target)` [tuple if `return_X_y` is True] New in version 0.18.

**sklearn.datasets.load_sample_image**

`sklearn.datasets.load_sample_image(image_name)`

Load the numpy array of a single sample image

Read more in the *User Guide*.

**Parameters**

- `image_name` [{`china.jpg`, `flower.jpg`}] The name of the sample image loaded

**Returns**

- `img` [3D array] The image as a numpy array: height x width x color

**Examples**

```python
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')  # doctest: +SKIP
>>> china.dtype  # doctest: +SKIP
dtype('uint8')
>>> china.shape  # doctest: +SKIP
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg')  # doctest: +SKIP
```

(continues on next page)
Examples using `sklearn.datasets.load_sample_image`

- **Color Quantization using K-Means**

**sklearn.datasets.load_sample_images**

`sklearn.datasets.load_sample_images()`  
Load sample images for image manipulation.  
Loads both, `china` and `flower`.  
Read more in the User Guide.

**Returns**

data [Bunch] Dictionary-like object with the following attributes:  
`images`, the two sample images,  
`filenames`, the file names for the images,  
and `'DESCR'` the full description of the dataset.

**Examples**

To load the data and visualize the images:

```python  
>>> from sklearn.datasets import load_sample_images  
>>> dataset = load_sample_images()  
>>> len(dataset.images)  
2  
>>> first_img_data = dataset.images[0]  
>>> first_img_data.shape  
(427, 640, 3)  
>>> first_img_data.dtype  
dtype('uint8')
```

**sklearn.datasets.load_svmlight_file**

`sklearn.datasets.load_svmlight_file(f, n_features=None, dtype=<class 'numpy.float64'>, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)`

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.
Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with joblib.Memory.cache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

https://github.com/mblondel/svmlight-loader

**Parameters**

- **f** ([str, file-like, int]) (Path to) a file to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

- **n_features** [int or None] The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. n_features is only required if offset or length are passed a non-default value.

- **dtype** [numpy data type, default np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays X and y.

- **multilabel** [boolean, optional, default False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

- **zero_based** [boolean or “auto”, optional, default “auto”] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

- **query_id** [boolean, default False] If True, will return the query_id array for each file.

- **offset** [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

- **length** [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

**Returns**

- **X** [scipy.sparse matrix of shape (n_samples, n_features)]

- **y** [ndarray of shape (n_samples,), or, in the multilabel a list of] tuples of length n_samples.

- **query_id** [array of shape (n_samples,)] query_id for each sample. Only returned when query_id is set to True.

**See also:**
**load_svmlight_files** similar function for loading multiple files in this format, enforcing the same number of features/columns on all of them.

**Examples**

To use joblib.Memory to cache the svmlight file:

```python
from joblib import Memory
from .datasets import load_svmlight_file

mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

**sklearn.datasets.load_svmlight_files**

Load dataset from multiple files in SVMlight format

This function is equivalent to mapping `load_svmlight_file` over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the `query_id` parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

**Parameters**

- `files` [iterable over {str, file-like, int}] (Paths of) files to load. If a path ends in ".gz" or ".bz2", it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-like objects will not be closed by this function. File-like objects must be opened in binary mode.

- `n_features` [int or None] The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

  This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

- `dtype` [numpy data type, default `numpy.float64`] Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

- `multilabel` [boolean, optional] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

- `zero_based` [boolean or "auto", optional] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to "auto", a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length
is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id [boolean, defaults to False] If True, will return the query_id array for each file.

offset [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

[X1, y1, ..., Xn, yn]
where each (Xi, yi) pair is the result from load_svmlight_file(files[i]).
If query_id is set to True, this will return instead [X1, y1, q1, ...
..., Xn, yn, qn] where (Xi, yi, qi) is the result from
load_svmlight_file(files[i])

See also:
load_svmlight_file

Notes

When fitting a model to a matrix X_train and evaluating it against a matrix X_test, it is essential that X_train and X_test have the same number of features (X_train.shape[1] == X_test.shape[1]). This may not be the case if you load the files individually with load_svmlight_file.

sklearn.datasets.load_wine

sklearn.datasets.load_wine(return_X_y=False)
Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

Read more in the User Guide.

Parameters

return_X_y [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘target_names’, the meaning of the labels, ‘feature_names’, the meaning of the features, and ‘DESCR’, the full description of the dataset.
The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit standard format from: https://archive.ics.uci.edu/ml/machine-learning-databases/wine/wine.data

Examples

Let’s say you are interested in the samples 10, 80, and 140, and want to know their class name.

```python
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

**sklearn.datasets.make_biclusters**

**sklearn.datasets.make_biclusters** *(shape, n_clusters, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)*

Generate an array with constant block diagonal structure for biclustering.

Read more in the *User Guide*.

**Parameters**

- **shape** [iterable (n_rows, n_cols)] The shape of the result.
- **n_clusters** [integer] The number of biclusters.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- **minval** [int, optional (default=10)] Minimum value of a bicluster.
- **maxval** [int, optional (default=100)] Maximum value of a bicluster.
- **shuffle** [boolean, optional (default=True)] Shuffle the samples.
- **random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- **X** [array of shape shape] The generated array.
- **rows** [array of shape (n_clusters, X.shape[0]),] The indicators for cluster membership of each row.
- **cols** [array of shape (n_clusters, X.shape[1]),] The indicators for cluster membership of each column.

See also:

- **make_checkerboard**

**References**

[1]

**sklearn.datasets.make_blobs**

`sklearn.datasets.make_blobs(n_samples=100, n_features=2, centers=None, cluster_std=1.0, center_box=(-10.0, 10.0), shuffle=True, random_state=None)`

Generate isotropic Gaussian blobs for clustering.

Read more in the User Guide.

**Parameters**

- `n_samples` [int or array-like, optional (default=100)] If int, it is the total number of points equally divided among clusters. If array-like, each element of the sequence indicates the number of samples per cluster.

- `n_features` [int, optional (default=2)] The number of features for each sample.

- `centers` [int or array of shape [n_centers, n_features], optional] (default=None) The number of centers to generate, or the fixed center locations. If `n_samples` is an int and `centers` is None, 3 centers are generated. If `n_samples` is array-like, centers must be either None or an array of length equal to the length of `n_samples`.

- `cluster_std` [float or sequence of floats, optional (default=1.0)] The standard deviation of the clusters.

- `center_box` [pair of floats (min, max), optional (default=(-10.0, 10.0))] The bounding box for each cluster center when centers are generated at random.

- `shuffle` [boolean, optional (default=True)] Shuffle the samples.

- `random_state` [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- `X` [array of shape [n_samples, n_features]] The generated samples.

- `y` [array of shape [n_samples]] The integer labels for cluster membership of each sample.

See also:

`make_classification` a more intricate variant

**Examples**

```python
>>> from sklearn.datasets import make_blobs
>>> X, y = make_blobs(n_samples=10, centers=3, n_features=2, ...
...                   random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 0, 1, 0, 2, 2, 2, 1, 1, 0])
>>> X, y = make_blobs(n_samples=[3], centers=None, n_features=2, ...
...                   random_state=0)
>>> print(X.shape)
(10, 2)

`sklearn.datasets.make_checkerboard`

`sklearn.datasets.make_checkerboard(shape, n_clusters, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)`

Generate an array with block checkerboard structure for biclustering.

Read more in the [User Guide](https://scikit-learn.org/0.22/modules/generated/sklearn.datasets.make_checkerboard.html).

**Parameters**

- `shape` [iterable (n_rows, n_cols)] The shape of the result.
n_clusters [integer or iterable (n_row_clusters, n_column_clusters)] The number of row and
column clusters.
noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.
minval [int, optional (default=10)] Minimum value of a bicluster.
maxval [int, optional (default=100)] Maximum value of a bicluster.
shuffle [boolean, optional (default=True)] Shuffle the samples.
random_state [int, RandomState instance or None (default)] Determines random number gen-
eration for dataset creation. Pass an int for reproducible output across multiple function
calls. See Glossary.

Returns
X [array of shape shape] The generated array.
rows [array of shape (n_clusters, X.shape[0],)] The indicators for cluster membership of each
row.
cols [array of shape (n_clusters, X.shape[1],)] The indicators for cluster membership of each
column.

sklearn.datasets.make_circles

sklearn.datasets.make_circles (n_samples=100, shuffle=True, noise=None, random_state=None,
factor=0.8)
Make a large circle containing a smaller circle in 2d.
A simple toy dataset to visualize clustering and classification algorithms.
Read more in the User Guide.

Parameters
n_samples [int, optional (default=100)] The total number of points generated. If odd, the inner
circle will have one point more than the outer circle.
shuffle [bool, optional (default=True)] Whether to shuffle the samples.
noise [double or None (default=None)] Standard deviation of Gaussian noise added to the data.
random_state [int, RandomState instance or None (default)] Determines random number gen-
eration for dataset shuffling and noise. Pass an int for reproducible output across multiple
function calls. See Glossary.
factor [0 < double < 1 (default=.8)] Scale factor between inner and outer circle.
Returns

X  [array of shape [n_samples, 2]] The generated samples.

y  [array of shape [n_samples]] The integer labels (0 or 1) for class membership of each sample.

sklearn.datasets.make_classification

sklearn.datasets.make_classification(n_samples=100, n_features=20, n_informative=2, n_redundant=2, n_repeated=0, n_classes=2, n_clusters_per_class=2, weights=None, flip_y=0.01, class_sep=1.0, hypercube=True, shift=0.0, scale=1.0, shuffle=True, random_state=None)

Generate a random n-class classification problem.

This initially creates clusters of points normally distributed (std=1) about vertices of an n_informative-dimensional hypercube with sides of length 2*class_sep and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Without shuffling, X horizontally stacks features in the following order: the primary n_informative features, followed by n_redundant linear combinations of the informative features, followed by n_repeated duplicates, drawn randomly with replacement from the informative and redundant features. The remaining features are filled with random noise. Thus, without shuffling, all useful features are contained in the columns X[:, :n_informative + n_redundant + n_repeated].

Read more in the User Guide.

Parameters

n_samples  [int, optional (default=100)] The number of samples.

n_features  [int, optional (default=20)] The total number of features. These comprise n_informative informative features, n_redundant redundant features, n_repeated duplicated features and n_features-n_informative-n_redundant-n_repeated useless features drawn at random.
n_informative [int, optional (default=2)] The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension n_informative. For each cluster, informative features are drawn independently from N(0, 1) and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.

n_redundant [int, optional (default=2)] The number of redundant features. These features are generated as random linear combinations of the informative features.

n_repeated [int, optional (default=0)] The number of duplicated features, drawn randomly from the informative and the redundant features.

n_classes [int, optional (default=2)] The number of classes (or labels) of the classification problem.

n_clusters_per_class [int, optional (default=2)] The number of clusters per class.

weights [array-like of shape (n_classes,) or (n_classes - 1,), (default=None)] The proportions of samples assigned to each class. If None, then classes are balanced. Note that if len(weights) == n_classes - 1, then the last class weight is automatically inferred. More than n_samples samples may be returned if the sum of weights exceeds 1.

flip_y [float, optional (default=0.01)] The fraction of samples whose class is assigned randomly. Larger values introduce noise in the labels and make the classification task harder.

class_sep [float, optional (default=1.0)] The factor multiplying the hypercube size. Larger values spread out the clusters/classes and make the classification task easier.

hypercube [boolean, optional (default=True)] If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.

shift [float, array of shape [n_features] or None, optional (default=0.0)] Shift features by the specified value. If None, then features are shifted by a random value drawn in [-class_sep, class_sep].

scale [float, array of shape [n_features] or None, optional (default=1.0)] Multiply features by the specified value. If None, then features are scaled by a random value drawn in [1, 100]. Note that scaling happens after shifting.

shuffle [boolean, optional (default=True)] Shuffle the samples and the features.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for class membership of each sample.

sklearn.datasets.make_friedman1

sklearn.datasets.make_friedman1(n_samples=100, n_features=10, noise=0.0, random_state=None)

Generate the “Friedman #1” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are independent features uniformly distributed on the interval [0, 1]. The output y is created according to the formula:

\[
y(X) = 10 \times \sin(\pi \times X[:, 0] \times X[:, 1]) + 20 \times (X[:, 2] - 0.5)^2 + 10 \times X[:, 3] + 5 \times X[:, 4] + \text{noise} \times N(0, 1).
\]

Out of the n_features features, only 5 are actually used to compute y. The remaining features are independent of y.

The number of features has to be \( \geq 5 \).

Read more in the User Guide.

Parameters

- **n_samples** [int, optional (default=100)] The number of samples.
- **n_features** [int, optional (default=10)] The number of features. Should be at least 5.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
**random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- X [array of shape [n_samples, n_features]] The input samples.
- y [array of shape [n_samples]] The output values.

**References**

[1], [2]

**sklearn.datasets.make_friedman2**

```
sklearn.datasets.make_friedman2(n_samples=100, noise=0.0, random_state=None)
```

Generate the “Friedman #2” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are 4 independent features uniformly distributed on the intervals:

```
0 <= X[:, 0] <= 100,
40 * pi <= X[:, 1] <= 560 * pi,
0 <= X[:, 2] <= 1,
1 <= X[:, 3] <= 11.
```

The output y is created according to the formula:

```
y(X) = (X[:, 0] ** 2 + (X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) ** 2) ** 0.5 + noise * N(0, 1).
```

Read more in the *User Guide*.

**Parameters**

- **n_samples** [int, optional (default=100)] The number of samples.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- X [array of shape [n_samples, 4]] The input samples.
- y [array of shape [n_samples]] The output values.

**References**

[1], [2]
sklearn.datasets.make_friedman3

sklearn.datasets.make_friedman3(n_samples=100, noise=0.0, random_state=None)

Generate the “Friedman #3” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs $X$ are 4 independent features uniformly distributed on the intervals:

$0 \leq X[:, 0] \leq 100$,
$40 \times \pi \leq X[:, 1] \leq 560 \times \pi$,
$0 \leq X[:, 2] \leq 1$,
$1 \leq X[:, 3] \leq 11$.

The output $y$ is created according to the formula:

$$y(X) = \arctan((X[:, 1] \times X[:, 2] - 1 / (X[:, 1] \times X[:, 3])) / X[:, 0]) + \text{noise} \cdot \mathcal{N}(0, 1).$$

Read more in the User Guide.

Parameters

- **n_samples** [int, optional (default=100)] The number of samples.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- $X$ [array of shape [n_samples, 4]] The input samples.
- $y$ [array of shape [n_samples]] The output values.

sklearn.datasets.make_gaussian_quantiles

sklearn.datasets.make_gaussian_quantiles(mean=None, cov=1.0, n_samples=100, n_features=2, n_classes=3, shuffle=True, random_state=None)

Generate isotropic Gaussian and label samples by quantile

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the $\chi^2$ distribution).

Read more in the User Guide.

Parameters

- **mean** [array of shape [n_features], optional (default=None)] The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).
cov [float, optional (default=1.)] The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.

n_samples [int, optional (default=100)] The total number of points equally divided among classes.

n_features [int, optional (default=2)] The number of features for each sample.

n_classes [int, optional (default=3)] The number of classes

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for quantile membership of each sample.

Notes

The dataset is from Zhu et al [1].

References

[1]

- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees

sklearn.datasets.make_hastie_10_2

sklearn.datasets.make_hastie_10_2 (n_samples=12000, random_state=None)
Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target y is defined by:

\[ y[i] = 1 \text{ if } \sum X[i] ** 2 > 9.34 \text{ else } -1 \]

Read more in the User Guide.

Parameters

n_samples [int, optional (default=12000)] The number of samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns
X  [array of shape [n_samples, 10]] The input samples.

y  [array of shape [n_samples]] The output values.

`sklearn.datasets.make_low_rank_matrix`

`sklearn.datasets.make_low_rank_matrix(n_samples=100, n_features=100, effective_rank=10, tail_strength=0.5, random_state=None)`

Generate a mostly low rank matrix with bell-shaped singular values

Most of the variance can be explained by a bell-shaped curve of width `effective_rank`: the low rank part of the singular values profile is:

\[(1 - \text{tail_strength}) \times \exp(-1.0 \times (i / \text{effective_rank}) ^ 2)\]

The remaining singular values’ tail is fat, decreasing as:

\[\text{tail_strength} \times \exp(-0.1 \times i / \text{effective_rank})\]

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

This kind of singular profiles is often seen in practice, for instance:

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

Read more in the `User Guide`.

Parameters

- `n_samples` [int, optional (default=100)] The number of samples.
- `n_features` [int, optional (default=100)] The number of features.
- `effective_rank` [int, optional (default=10)] The approximate number of singular vectors required to explain most of the data by linear combinations.
- `tail_strength` [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile.
random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns
X [array of shape [n_samples, n_features]] The matrix.

sklearn.datasets.make_moons

sklearn.datasets.make_moons (n_samples=100, shuffle=True, noise=None, random_state=None)
Make two interleaving half circles
A simple toy dataset to visualize clustering and classification algorithms. Read more in the User Guide.

Parameters
n_samples [int, optional (default=100)] The total number of points generated.
shuffle [bool, optional (default=True)] Whether to shuffle the samples.
noise [double or None (default=None)] Standard deviation of Gaussian noise added to the data.
random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns
X [array of shape [n_samples, 2]] The generated samples.
y [array of shape [n_samples]] The integer labels (0 or 1) for class membership of each sample.

Examples using sklearn.datasets.make_moons

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Classifier comparison
- Comparing different hierarchical linkage methods on toy datasets
- Comparing different clustering algorithms on toy datasets
- Varying regularization in Multi-layer Perceptron
- Compare Stochastic learning strategies for MLPClassifier
- Feature discretization

sklearn.datasets.make_multilabel_classification

sklearn.datasets.make_multilabel_classification (n_samples=100, n_features=20, n_classes=5, n_labels=2, length=50, allow_unlabeled=True, sparse=False, return_indicator='dense', return_distributions=False, random_state=None)

Generate a random multilabel classification problem.
For each sample, the generative process is:
• pick the number of labels: \( n \sim \text{Poisson}(n\_\text{labels}) \)
• \( n \) times, choose a class \( c \): \( c \sim \text{Multinomial}(\theta) \)
• pick the document length: \( k \sim \text{Poisson}(\text{length}) \)
• \( k \) times, choose a word: \( w \sim \text{Multinomial}(\theta_c) \)

In the above process, rejection sampling is used to make sure that \( n \) is never zero or more than \( n\_\text{classes} \), and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the *User Guide*.

Parameters

- **n_samples** [int, optional (default=100)] The number of samples.
- **n_features** [int, optional (default=20)] The total number of features.
- **n_classes** [int, optional (default=5)] The number of classes of the classification problem.
- **n_labels** [int, optional (default=2)] The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with \( n\_\text{labels} \) as its expected value, but samples are bounded (using rejection sampling) by \( n\_\text{classes} \), and must be nonzero if \( \text{allow\_unlabeled} \) is False.
- **length** [int, optional (default=50)] The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.
- **allow_unlabeled** [bool, optional (default=True)] If True, some instances might not belong to any class.
- **sparse** [bool, optional (default=False)] If True, return a sparse feature matrix
  
  New in version 0.17: parameter to allow sparse output.
- **return_indicator** ['dense' (default) | 'sparse' | False] If dense return \( Y \) in the dense binary indicator format. If 'sparse' return \( Y \) in the sparse binary indicator format. False returns a list of lists of labels.
- **return_distributions** [bool, optional (default=False)] If True, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.
- **random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

- **X** [array of shape \([n\_\text{samples}, n\_\text{features}]\)] The generated samples.
- **Y** [array or sparse CSR matrix of shape \([n\_\text{samples}, n\_\text{classes}]\)] The label sets.
- **p_c** [array, shape \([n\_\text{classes}]\)] The probability of each class being drawn. Only returned if \( \text{return\_distributions} = \text{True} \).
- **p_w_c** [array, shape \([n\_\text{features}, n\_\text{classes}]\)] The probability of each feature being drawn given each class. Only returned if \( \text{return\_distributions} = \text{True} \).

Examples using \texttt{sklearn.datasets.make_multilabel_classification}

- *Multilabel classification*
- *Plot randomly generated multilabel dataset*
Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See `make_low_rank_matrix` for more details.

The output is generated by applying a (potentially biased) random linear regression model with \( n_{\text{ininformative}} \) nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the User Guide.

Parameters

- \( n_{\text{samples}} \) [int, optional (default=100)] The number of samples.
- \( n_{\text{features}} \) [int, optional (default=100)] The number of features.
- \( n_{\text{informative}} \) [int, optional (default=10)] The number of informative features, i.e., the number of features used to build the linear model used to generate the output.
- \( n_{\text{targets}} \) [int, optional (default=1)] The number of regression targets, i.e., the dimension of the \( y \) output vector associated with a sample. By default, the output is a scalar.
- \( \text{bias} \) [float, optional (default=0.0)] The bias term in the underlying linear model.
- \( \text{effective_rank} \) [int or None, optional (default=None)]
  - if not None: The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.
  - if None: The input set is well conditioned, centered and gaussian with unit variance.
- \( \text{tail_strength} \) [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile if \( \text{effective_rank} \) is not None.
- \( \text{noise} \) [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
- \( \text{shuffle} \) [boolean, optional (default=True)] Shuffle the samples and the features.
- \( \text{coef} \) [boolean, optional (default=False)] If True, the coefficients of the underlying linear model are returned.
- \( \text{random_state} \) [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- \( X \) [array of shape \([n_{\text{samples}}, n_{\text{features}}]\)] The input samples.
- \( y \) [array of shape \([n_{\text{samples}}]\) or \([n_{\text{samples}}, n_{\text{targets}}]\)] The output values.
- \( \text{coef} \) [array of shape \([n_{\text{features}}]\) or \([n_{\text{features}}, n_{\text{targets}}]\), optional] The coefficient of the underlying linear model. It is returned only if \( \text{coef} \) is True.
Examples using `sklearn.datasets.make_regression`

- Prediction Latency
- Plot Ridge coefficients as a function of the L2 regularization
- Robust linear model estimation using RANSAC
- HuberRegressor vs Ridge on dataset with strong outliers
- Lasso on dense and sparse data
- Effect of transforming the targets in regression model

`sklearn.datasets.make_s_curve`

`sklearn.datasets.make_s_curve(n_samples=100, noise=0.0, random_state=None)`

Generate an S curve dataset.

Read more in the User Guide.

Parameters

- `n_samples` [int, optional (default=100)] The number of sample points on the S curve.
- `noise` [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- `random_state` [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- `X` [array of shape [n_samples, 3]] The points.
- `t` [array of shape [n_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

Examples using `sklearn.datasets.make_s_curve`

- Comparison of Manifold Learning methods
- t-SNE: The effect of various perplexity values on the shape

`sklearn.datasets.make_sparse_coded_signal`

`sklearn.datasets.make_sparse_coded_signal(n_samples, n_components, n_features, n_nonzero_coefs, random_state=None)`

Generate a signal as a sparse combination of dictionary elements.

Returns a matrix Y = DX, such as D is (n_features, n_components), X is (n_components, n_samples) and each column of X has exactly n_nonzero_coefs non-zero elements.

Read more in the User Guide.

Parameters

- `n_samples` [int] number of samples to generate
- `n_components` [int,] number of components in the dictionary
**n_features** [int] number of features of the dataset to generate

**n_nonzero_coefs** [int] number of active (non-zero) coefficients in each sample

**random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

**data** [array of shape [n_features, n_samples]] The encoded signal (Y).

**dictionary** [array of shape [n_features, n_components]] The dictionary with normalized components (D).

**code** [array of shape [n_components, n_samples]] The sparse code such that each column of this matrix has exactly n_nonzero_coefs non-zero items (X).

Examples using `sklearn.datasets.make_sparse_coded_signal`

- **Orthogonal Matching Pursuit**

`sklearn.datasets.make_sparse_spd_matrix`

`sklearn.datasets.make_sparse_spd_matrix(dim=1, alpha=0.95, norm_diag=False, smallest_coef=0.1, largest_coef=0.9, random_state=None)`

Generate a sparse symmetric definite positive matrix.

Read more in the User Guide.

Parameters

**dim** [integer, optional (default=1)] The size of the random matrix to generate.

**alpha** [float between 0 and 1, optional (default=0.95)] The probability that a coefficient is zero (see notes). Larger values enforce more sparsity.

**norm_diag** [boolean, optional (default=False)] Whether to normalize the output matrix to make the leading diagonal elements all 1

**smallest_coef** [float between 0 and 1, optional (default=0.1)] The value of the smallest coefficient.

**largest_coef** [float between 0 and 1, optional (default=0.9)] The value of the largest coefficient.

**random_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

**prec** [sparse matrix of shape (dim, dim)] The generated matrix.

See also:

`make_spd_matrix`
Notes

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into the filling fraction of the matrix itself.

Examples using `sklearn.datasets.make_sparse_spd_matrix`

- Sparse inverse covariance estimation

`sklearn.datasets.make_sparse_uncorrelated`

```python
sklearn.datasets.make_sparse_uncorrelated(n_samples=100, n_features=10, random_state=None)
```

Generate a random regression problem with sparse uncorrelated design

This dataset is described in Celeux et al [1]. as:

\[
X \sim N(0, 1) \\
y(X) = X[:, 0] + 2 \times X[:, 1] - 2 \times X[:, 2] - 1.5 \times X[:, 3]
\]

Only the first 4 features are informative. The remaining features are useless.

Read more in the User Guide.

Parameters

- `n_samples` [int, optional (default=100)] The number of samples.
- `n_features` [int, optional (default=10)] The number of features.
- `random_state` [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- `X` [array of shape [n_samples, n_features]] The input samples.
- `y` [array of shape [n_samples]] The output values.

References

[1]

`sklearn.datasets.make_spd_matrix`

```python
sklearn.datasets.make_spd_matrix(n_dim, random_state=None)
```

Generate a random symmetric, positive-definite matrix.

Read more in the User Guide.

Parameters

- `n_dim` [int] The matrix dimension.
- `random_state` [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.
Returns

X [array of shape [n_dim, n_dim]] The random symmetric, positive-definite matrix.

See also:

make_sparse_spd_matrix

sklearn.datasets.make_swiss_roll

sklearn.datasets.make_swiss_roll (n_samples=100, noise=0.0, random_state=None)
Generate a swiss roll dataset.
Read more in the User Guide.

Parameters

n_samples [int, optional (default=100)] The number of sample points on the S curve.
noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.
random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [array of shape [n_samples, 3]] The points.
t [array of shape [n_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

Notes

The algorithm is from Marsland [1].

References

[1]

Examples using sklearn.datasets.make_swiss_roll

- Hierarchical clustering: structured vs unstructured ward
- Swiss Roll reduction with LLE

7.8 sklearn.decomposition: Matrix Decomposition

The sklearn.decomposition module includes matrix decomposition algorithms, including among others PCA, NMF or ICA. Most of the algorithms of this module can be regarded as dimensionality reduction techniques.

User guide: See the Decomposing signals in components (matrix factorization problems) section for further details.
Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

$$(U^*, V^*) = \arg\min_{(U, V)} 0.5 \| Y - U V \|^2_2 + \alpha \| U \|_1$$

with $\| V_k \|_2 = 1$ for all $0 \leq k < n_{\text{components}}$

Read more in the User Guide.

**Parameters**

- **n_components** [int, default=n_features] number of dictionary elements to extract
- **alpha** [float, default=1.0] sparsity controlling parameter
- **max_iter** [int, default=1000] maximum number of iterations to perform
- **tol** [float, default=1e-8] tolerance for numerical error
fit_algorithm [{'lars', 'cd'}, default='lars'] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

New in version 0.17: cd coordinate descent method to improve speed.

transform_algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='omp'] Algorithm used to transform the data lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'

New in version 0.17: lasso_cd coordinate descent method to improve speed.

transform_n_nonzero_coefs [int, default=0.1*n_features] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case.

transform_alpha [float, default=1.0] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.

n_jobs [int or None, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

code_init [array of shape (n_samples, n_components), default=None] initial value for the code, for warm restart

dict_init [array of shape (n_components, n_features), default=None] initial values for the dictionary, for warm restart

verbose [bool, default=False] To control the verbosity of the procedure.

split_sign [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

random_state [int, RandomState instance or None, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

positive_dict [bool, default=False] Whether to enforce positivity when finding the dictionary

New in version 0.20.

transform_max_iter [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or lasso_lars.

New in version 0.22.

Attributes
components_ [array, [n_components, n_features]] dictionary atoms extracted from the data

error_ [array] vector of errors at each iteration

n_iter_ [int] Number of iterations run.

Methods

```python
fit(self, X[, y]) Fit the model from data in X.

fit_transform(self, X[, y]) Fit to data, then transform it.

get_params(self[, deep]) Get parameters for this estimator.

set_params(self[, **params]) Set the parameters of this estimator.

transform(self, X) Encode the data as a sparse combination of the dictionary atoms.
```

```python
__init__(self, n_components=None, alpha=1, max_iter=1000, tol=1e-08, fit_algorithm='lars',
         transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None,
         n_jobs=None, code_init=None, dict_init=None, verbose=False, split_sign=False,
         random_state=None, positive_code=False, positive_dict=False, transform_max_iter=1000)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Fit the model from data in X.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [Ignored]

Returns

- **self** [object] Returns the object itself

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params *(self, deep=True)*

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform *(self, X)*

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data

7.8.2 `sklearn.decomposition.FactorAnalysis`

class `sklearn.decomposition.FactorAnalysis`(n_components=None, tol=0.01, copy=True, max_iter=1000, noise_variance_init=None, svd_method='randomized', iterated_power=3, random_state=0)

Factor Analysis (FA)

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain PPCA.
FactorAnalysis performs a maximum likelihood estimate of the so-called loading matrix, the transformation of the latent variables to the observed ones, using SVD based approach.

Read more in the User Guide.

New in version 0.13.

Parameters

- **n_components** [int | None] Dimensionality of latent space, the number of components of X that are obtained after transform. If None, n_components is set to the number of features.
- **tol** [float] Stopping tolerance for log-likelihood increase.
- **copy** [bool] Whether to make a copy of X. If False, the input X gets overwritten during fitting.
- **max_iter** [int] Maximum number of iterations.
- **noise_variance_init** [None | array, shape=(n_features,)] The initial guess of the noise variance for each feature. If None, it defaults to np.ones(n_features)
- **svd_method** [{'lapack', 'randomized'}] Which SVD method to use. If ‘lapack’ use standard SVD from scipy.linalg, if ‘randomized’ use fast randomized_svd function. Defaults to ‘randomized’. For most applications ‘randomized’ will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for iterated_power. If this is not sufficient, for maximum precision you should choose ‘lapack’.
- **iterated_power** [int, optional] Number of iterations for the power method. 3 by default. Only used if svd_method equals ‘randomized’
- **random_state** [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Only used when svd_method equals ‘randomized’.

Attributes

- **components_** [array, [n_components, n_features]] Components with maximum variance.
- **loglike_** [list, [n_iterations]] The log likelihood at each iteration.
- **noise_variance_** [array, shape=(n_features,)] The estimated noise variance for each feature.
- **n_iter_** [int] Number of iterations run.
- **mean_** [array, shape=(n_features,)] Per-feature empirical mean, estimated from the training set.

See also:

**PCA** Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

**FastICA** Independent component analysis, a latent variable model with non-Gaussian latent variables.

References

Examples
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FactorAnalysis
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FactorAnalysis(n_components=7, random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)

Methods

**fit**(self, X[, y])

Fit the FactorAnalysis model to X using SVD based approach

**fit_transform**(self, X[, y])

Fit to data, then transform it.

**get_covariance**(self)

Compute data covariance with the FactorAnalysis model.

**get_params**(self[, deep])

Get parameters for this estimator.

**get_precision**(self)

Compute data precision matrix with the FactorAnalysis model.

**score**(self, X[, y])

Compute the average log-likelihood of the samples

**score_samples**(self, X)

Compute the log-likelihood of each sample

**set_params**(self, **params)

Set the parameters of this estimator.

**transform**(self, X)

Apply dimensionality reduction to X using the model.

__init__**(self, n_components=None, tol=0.01, copy=True, max_iter=1000, noise_variance_init=None, svd_method='randomized', iterated_power=3, random_state=0)

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y=None)

Fit the FactorAnalysis model to X using SVD based approach

**Parameters**

X [array-like, shape (n_samples, n_features)] Training data.

y [Ignored]

**Returns**

self

**fit_transform**(self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

**Returns**

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.
get_covariance (self)
Compute data covariance with the FactorAnalysis model.

cov = components_.T * components_ + diag(noise_variance)

Returns

cov [array, shape (n_features, n_features)] Estimated covariance of data.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision (self)
Compute data precision matrix with the FactorAnalysis model.

Returns

precision [array, shape (n_features, n_features)] Estimated precision of data.

score (self, X, y=None)
Compute the average log-likelihood of the samples

Parameters

X [array, shape (n_samples, n_features)] The data
y [Ignored]

Returns

ll [float] Average log-likelihood of the samples under the current model

score_samples (self, X)
Compute the log-likelihood of each sample

Parameters

X [array, shape (n_samples, n_features)] The data

Returns

ll [array, shape (n_samples,) Log-likelihood of each sample under the current model

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.
**transform** *(self, X)*

Apply dimensionality reduction to X using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

**Parameters**

- X : array-like, shape (n_samples, n_features) Training data.

**Returns**

- X_new : array-like, shape (n_samples, n_components) The latent variables of X.

**Examples using sklearn.decomposition.FactorAnalysis**

- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Faces dataset decompositions

### 7.8.3 sklearn.decomposition.FastICA

**class sklearn.decomposition.FastICA**(n_components=None, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None)

FastICA: a fast algorithm for Independent Component Analysis.

**Parameters**

- n_components: int, optional] Number of components to use. If none is passed, all are used.
- algorithm: [{'parallel', 'deflation'}] Apply parallel or deflational algorithm for FastICA.
- whiten: [boolean, optional] If whitened is false, the data is already considered to be whitened, and no whitening is performed.
- fun: [string or function, optional. Default: 'logcosh'] The functional form of the G function used in the approximation to neg-entropy. Could be either 'logcosh', 'exp', or 'cube'. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

```python
def my_g(x):
    return x ** 3, (3 * x ** 2).mean(axis=-1)
```
- fun_args: [dictionary, optional] Arguments to send to the functional form. If empty and if fun='logcosh', fun_args will take value {'alpha': 1.0}.
- max_iter: [int, optional] Maximum number of iterations during fit.
- tol: [float, optional] Tolerance on update at each iteration.
- w_init: [None of an (n_components, n_components) ndarray] The mixing matrix to be used to initialize the algorithm.
- random_state: [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Attributes**
components_ [2D array, shape (n_components, n_features)] The linear operator to apply to the data to get the independent sources. This is equal to the unmixing matrix when whiten is False, and equal to np.dot(unmixing_matrix, self.whitening_) when whiten is True.

mixing_ [array, shape (n_features, n_components)] The pseudo-inverse of components_. It is the linear operator that maps independent sources to the data.

mean_ [array, shape(n_features)] The mean over features. Only set if self.whiten is True.

n_iter_ [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

whitening_ [array, shape (n_components, n_features)] Only set if whiten is ‘True’. This is the pre-whitening matrix that projects data onto the first n_components principal components.

Notes

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FastICA

>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FastICA(n_components=7,
                          random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Methods

```
fit(self, X[, y])  Fit the model to X.
fit_transform(self, X[, y])  Fit the model and recover the sources from X.
get_params(self[, deep])  Get parameters for this estimator.
inverse_transform(self, X[, copy])  Transform the sources back to the mixed data (apply mixing matrix).
set_params(self, **params)  Set the parameters of this estimator.
transform(self, X[, copy])  Recover the sources from X (apply the unmixing matrix).
```

__init__ (self, n_components=None, algorithm='parallel', whiten= True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Fit the model to X.

Parameters

X  [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number
of samples and \( n \text{\_features} \) is the number of features.

\[ y \quad [\text{Ignored}] \]

Returns

self

**fit\_transform**(\(self, X, y=None\))

Fit the model and recover the sources from \( X \).

Parameters

\( X \quad [\text{array-like, shape (n\_samples, n\_features)}] \) Training data, where \( n \text{\_samples} \) is the number of samples and \( n \text{\_features} \) is the number of features.

\( y \quad [\text{Ignored}] \)

Returns

\( X\_new \quad [\text{array-like, shape (n\_samples, n\_components)}] \)

**get\_params**(\(self, deep=True\))

Get parameters for this estimator.

Parameters

\( deep \quad [\text{bool, default=True}] \) If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

\( params \quad [\text{mapping of string to any}] \) Parameter names mapped to their values.

**inverse\_transform**(\(self, X, copy=True\))

Transform the sources back to the mixed data (apply mixing matrix).

Parameters

\( X \quad [\text{array-like, shape (n\_samples, n\_components)}] \) Sources, where \( n \text{\_samples} \) is the number of samples and \( n \text{\_components} \) is the number of components.

\( copy \quad [\text{bool (optional)}] \) If False, data passed to fit are overwritten. Defaults to True.

Returns

\( X\_new \quad [\text{array-like, shape (n\_samples, n\_features)}] \)

**set\_params**(\(self, **params\))

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

\( **params \quad [\text{dict}] \) Estimator parameters.

Returns

self \( [\text{object}] \) Estimator instance.

**transform**(\(self, X, copy=True\))

Recover the sources from \( X \) (apply the unmixing matrix).

Parameters
X [array-like, shape (n_samples, n_features)] Data to transform, where n_samples is the number of samples and n_features is the number of features.

copy [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples using sklearn.decomposition.FastICA

- Blind source separation using FastICA
- FastICA on 2D point clouds
- Faces dataset decompositions

7.8.4 sklearn.decomposition.IncrementalPCA

class sklearn.decomposition.IncrementalPCA(n_components=None, whiten=False, copy=True, batch_size=None)

Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of the data, keeping only the most significant singular vectors to project the data to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA, and allows sparse input.

This algorithm has constant memory complexity, on the order of $\text{batch\_size} \times \text{n\_features}$, enabling use of np.memmap files without loading the entire file into memory. For sparse matrices, the input is converted to dense in batches (in order to be able to subtract the mean) which avoids storing the entire dense matrix at any one time.

The computational overhead of each SVD is $O(\text{batch\_size} \times \text{n\_features}^2)$, but only $2 * \text{batch\_size}$ samples remain in memory at a time. There will be $\text{n\_samples} / \text{batch\_size}$ SVD computations to get the principal components, versus 1 large SVD of complexity $O(\text{n\_samples} \times \text{n\_features}^2)$ for PCA.

Read more in the User Guide.

New in version 0.16.

Parameters

- n_components [int or None, (default=None)] Number of components to keep. If n_components is None, then n_components is set to min(n_samples, n_features).

- whiten [bool, optional] When True (False by default) the components_ vectors are divided by n_samples times components_ to ensure uncorrelated outputs with unit component-wise variances.

  Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.

- copy [bool, (default=True)] If False, X will be overwritten. copy=False can be used to save memory but is unsafe for general use.
batch_size [int or None, (default=None)] The number of samples to use for each batch. Only used when calling fit. If batch_size is None, then batch_size is inferred from the data and set to $5 \times n\_features$, to provide a balance between approximation accuracy and memory consumption.

Attributes

components_ [array, shape (n_components, n_features)] Components with maximum variance.

explained_variance_ [array, shape (n_components,)] Variance explained by each of the selected components.

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

mean_ [array, shape (n_features,)] Per-feature empirical mean, aggregate over calls to partial_fit.

var_ [array, shape (n_features,)] Per-feature empirical variance, aggregate over calls to partial_fit.

n_components_ [int] The estimated number of components. Relevant when n_components=None.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across partial_fit calls.

TruncatedSVD

Notes

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is Matrix Computations, Third Edition, G. Holub and C. Van Loan, Chapter 5, section 5.4.4, pp 252-253.. This technique has been omitted because it is advantageous only when decomposing a matrix with n_samples (rows) >=
$5/3 * \text{n\_features (columns),}$ and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

References

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import IncrementalPCA
>>> from scipy import sparse

>>> X, _ = load_digits(return_X_y=True)
>>> transformer = IncrementalPCA(n_components=7, batch_size=200)
>>> transformer.partial_fit(X[:100, :])
>>> X_sparse = sparse.csr_matrix(X)
>>> X_transformed = transformer.fit_transform(X_sparse)
>>> X_transformed.shape
(1797, 7)
```

Methods

```python
fit(self, X[, y])
Fit the model with X, using minibatches of size batch_size.

fit_transform(self, X[, y])
Fit to data, then transform it.

get_covariance(self)
Compute data covariance with the generative model.

get_params(self[, deep])
Get parameters for this estimator.

get_precision(self)
Compute data precision matrix with the generative model.

inverse_transform(self, X)
Transform data back to its original space.

partial_fit(self, X[, y, check_input])
Incremental fit with X.

set_params(self, **params)
Set the parameters of this estimator.

transform(self, X)
Apply dimensionality reduction to X.
```

```python
__init__(self, n_components=None, whiten=False, copy=True, batch_size=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Fit the model with X, using minibatches of size batch_size.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]
```

Returns
self [object] Returns the instance itself.

**fit_transform**(self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_covariance**(self)

Compute data covariance with the generative model.

\[
\text{cov} = \text{components}_\cdot^T \ast \text{S} \ast \text{components} + \text{sigma2} \ast \text{eye(n_features)}
\]

where S contains the explained variances, and sigma2 contains the noise variances.

Returns

- **cov** [array, shape=(n_features, n_features)] Estimated covariance of data.

**get_params**(self, deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**get_precision**(self)

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns

- **precision** [array, shape=(n_features, n_features)] Estimated precision of data.

**inverse_transform**(self, X)

Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters

- **X** [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

- **X_original** array-like, shape (n_samples, n_features)
Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

**partial_fit** (self, X, y=None, check_input=True)
Incremental fit with X. All of X is processed as a single batch.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **check_input** [bool] Run check_array on X.
- **y** [Ignored]

Returns

- **self** [object] Returns the instance itself.

**set_params** (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

**transform** (self, X)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set, using minibatches of size batch_size if X is sparse.

Parameters

- **X** [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

- **X_new** [array-like, shape (n_samples, n_components)]

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X) # doctest: +SKIP
```
Examples using sklearn.decomposition.IncrementalPCA

- Incremental PCA

7.8.5 sklearn.decomposition.KernelPCA

class sklearn.decomposition.KernelPCA(n_components=None, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None, alpha=1.0, fit_inverse_transform=False, eigen_solver='auto', tol=0, max_iter=None, remove_zero_eig=False, random_state=None, copy_X=True, n_jobs=None)

Kernel Principal component analysis (KPCA)

Non-linear dimensionality reduction through the use of kernels (see Pairwise metrics, Affinities and Kernels).

Read more in the User Guide.

Parameters

n_components [int, default=None] Number of components. If None, all non-zero components are kept.

kernel ["linear" | "poly" | "rbf" | "sigmoid" | "cosine" | "precomputed"] Kernel. Default="linear".

gamma [float, default=1/n_features] Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels.

degree [int, default=3] Degree for poly kernels. Ignored by other kernels.

coef0 [float, default=1] Independent term in poly and sigmoid kernels. Ignored by other kernels.

kernel_params [mapping of string to any, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

alpha [int, default=1.0] Hyperparameter of the ridge regression that learns the inverse transform (when fit_inverse_transform=True).

fit_inverse_transform [bool, default=False] Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)

eigen_solver [string ['auto'|'dense'|'arpack'], default='auto'] Select eigensolver to use. If n_components is much less than the number of training samples, arpack may be more efficient than the dense eigensolver.

tol [float, default=0] Convergence tolerance for arpack. If 0, optimal value will be chosen by arpack.

max_iter [int, default=None] Maximum number of iterations for arpack. If None, optimal value will be chosen by arpack.

remove_zero_eig [boolean, default=False] If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be < n_components (and sometimes even zero due to numerical instability). When n_components is None, this parameter is ignored and components with zero eigenvalues are removed regardless.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when eigen_solver == ‘arpack’.
New in version 0.18.

**copy_X** [boolean, default=True] If True, input X is copied and stored by the model in the `X_fit_` attribute. If no further changes will be done to X, setting `copy_X=False` saves memory by storing a reference.

New in version 0.18.

**n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

New in version 0.18.

**Attributes**

- **lambdas_** [array, (n_components,)] Eigenvalues of the centered kernel matrix in decreasing order. If `n_components` and `remove_zero_eig` are not set, then all values are stored.

- **alphas_** [array, (n_samples, n_components)] Eigenvectors of the centered kernel matrix. If `n_components` and `remove_zero_eig` are not set, then all components are stored.

- **dual_coef_** [array, (n_samples, n_features)] Inverse transform matrix. Only available when `fit_inverse_transform` is True.

- **X_transformed_fit_** [array, (n_samples, n_components)] Projection of the fitted data on the kernel principal components. Only available when `fit_inverse_transform` is True.

- **X_fit_** [(n_samples, n_features)] The data used to fit the model. If `copy_X=False`, then `X_fit_` is a reference. This attribute is used for the calls to `transform`.

**References**

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import KernelPCA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = KernelPCA(n_components=7, kernel='linear')
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

Returns

self [object] Returns the instance itself.

fit_transform (self, X, y=None, **params)
Fit the model from data in X and transform X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)
Transform X back to original space.

Parameters

X [array-like, shape (n_samples, n_components)]

Returns

X_new [array-like, shape (n_samples, n_features)]

X_new [array-like, shape (n_samples, n_components)]

Examples using sklearn.decomposition.KernelPCA

- Kernel PCA

7.8.6 sklearn.decomposition.LatentDirichletAllocation

class sklearn.decomposition.LatentDirichletAllocation (n_components=10, doc_topic_prior=None, topic_word_prior=None, learning_method='batch', learning_decay=0.7, learning_offset=10.0, max_iter=10, batch_size=128, evaluate_every=-1, total_samples=1000000.0, perp_tol=0.1, mean_change_tol=0.001, max_doc_update_iter=100, n_jobs=None, verbose=0, random_state=None)

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the User Guide.

Parameters

n_components [int, optional (default=10)] Number of topics.

doc_topic_prior [float, optional (default=None)] Prior of document topic distribution \( \theta \). If the value is None, defaults to \( 1 / n\_components \). In [Re25e5648fc37-1], this is called alpha.

topic_word_prior [float, optional (default=None)] Prior of topic word distribution \( \beta \). If the value is None, defaults to \( 1 / n\_components \). In [Re25e5648fc37-1], this is called eta.

learning_method ['batch' | 'online', default='batch'] Method used to update _component. Only used in fit method. In general, if the data size is large, the online update will be much faster than the batch update.

7.8. sklearn.decomposition: Matrix Decomposition
Valid options:

`'batch'`: Batch variational Bayes method. Use all training data in each EM update. 
Old `components_` will be overwritten in each iteration.

`'online'`: Online variational Bayes method. In each EM update, use mini-batch of training data to update the `components_` variable incrementally. The learning rate is controlled by the `learning_decay` and the `learning_offset` parameters.

Changed in version 0.20: The default learning method is now "batch".

**learning_decay** [float, optional (default=0.7)] It is a parameter that control learning rate in the online learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic convergence. When the value is 0.0 and batch_size is n_samples, the update method is same as batch learning. In the literature, this is called kappa.

**learning_offset** [float, optional (default=10.)] A (positive) parameter that downweights early iterations in online learning. It should be greater than 1.0. In the literature, this is called tau_0.

**max_iter** [integer, optional (default=10)] The maximum number of iterations.

**batch_size** [int, optional (default=128)] Number of documents to use in each EM iteration. Only used in online learning.

**evaluate_every** [int, optional (default=0)] How often to evaluate perplexity. Only used in fit method. Set to 0 or negative number to not evaluate perplexity in training at all. Evaluating perplexity can help you check convergence in training process, but it will also increase total training time. Evaluating perplexity in every iteration might increase training time up to two-fold.

**total_samples** [int, optional (default=1e6)] Total number of documents. Only used in the partial_fit method.

**perp_tol** [float, optional (default=1e-1)] Perplexity tolerance in batch learning. Only used when evaluate_every is greater than 0.

**mean_change_tol** [float, optional (default=1e-3)] Stopping tolerance for updating document topic distribution in E-step.

**max_doc_update_iter** [int (default=100)] Max number of iterations for updating document topic distribution in the E-step.

**n_jobs** [int or None, optional (default=None)] The number of jobs to use in the E-step. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**verbose** [int, optional (default=0)] Verbosity level.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

**components_** [array, [n_components, n_features]] Variational parameters for topic word distribution. Since the complete conditional for topic word distribution is a Dirichlet, `components_[i, j]` can be viewed as pseudocount that represents the number of times word j was assigned to topic i. It can also be viewed as distribution over the words
for each topic after normalization: model.components_ / model.components_.
sum(axis=1)[..., np.newaxis].

**n_batch_iter_** [int] Number of iterations of the EM step.

**n_iter_** [int] Number of passes over the dataset.

**bound_** [float] Final perplexity score on training set.

**doc_topic_prior_** [float] Prior of document topic distribution theta. If the value is None, it is 1 / n_components.

**topic_word_prior_** [float] Prior of topic word distribution beta. If the value is None, it is 1 / n_components.

**References**

[Re25e5648fc37-1]

**Examples**

```python
>>> from sklearn.decomposition import LatentDirichletAllocation
>>> from sklearn.datasets import make_multilabel_classification
>>> # This produces a feature matrix of token counts, similar to what
>>> # CountVectorizer would produce on text.
>>> X, _ = make_multilabel_classification(random_state=0)
>>> lda = LatentDirichletAllocation(n_components=5, ...
...        random_state=0)
>>> lda.fit(X)
LatentDirichletAllocation(...)
>>> # get topics for some given samples:
>>> lda.transform(X[-2:])
array([[0.00360392, 0.25499205, 0.0036211 , 0.64236448, 0.09541846],
       [0.15297572, 0.00362644, 0.44412786, 0.39568399, 0.003586 ]])
```

__init__ (self, n_components=10, doc_topic_prior=None, topic_word_prior=None, learning_method='batch', learning_decay=0.7, learning_offset=10.0, max_iter=10, batch_size=128, evaluate_every=-1, total_samples=1000000.0, perp_tol=0.1, mean_change_tol=0.001, max_doc_update_iter=100, n_jobs=None, verbose=0, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)

Learn model for the data X with variational Bayes method.

When learning_method is ‘online’, use mini-batch update. Otherwise, use batch update.

Parameters
    X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.
    y [Ignored]

Returns
    self

fit_transform (self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
    X [numpy array of shape [n_samples, n_features]] Training set.
    y [numpy array of shape [n_samples]] Target values.
    **fit_params [dict] Additional fit parameters.

Returns
    X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters
    deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
    params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y=None)

Online VB with Mini-Batch update.

Parameters
    X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.
    y [Ignored]

Returns
    self

perplexity (self, X, sub_sampling=False)

Calculate approximate perplexity for data X.

Perplexity is defined as \(\exp(-1. \times \text{log-likelihood per word})\)
Changed in version 0.19: `doc_topic_distr` argument has been deprecated and is ignored because user no longer has access to unnormalized distribution

**Parameters**

- **X** [array-like or sparse matrix, [n_samples, n_features]] Document word matrix.
- **sub_sampling** [bool] Do sub-sampling or not.

**Returns**

- **score** [float] Perplexity score.

**score** *(self, X, y=None)*

Calculate approximate log-likelihood as score.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.
- **y** [Ignored]

**Returns**

- **score** [float] Use approximate bound as score.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*

Transform data X according to the fitted model.

Changed in version 0.18: `doc_topic_distr` is now normalized

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

**Returns**

- **doc_topic_distr** [shape=(n_samples, n_components)] Document topic distribution for X.

**Examples using sklearn.decomposition.LatentDirichletAllocation**

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

\[
(U^*, V^*) = \arg\min_{U, V} 0.5 \| Y - U V \|_2^2 + \alpha \| U \|_1
\]

with \( \| V_k \|_2 = 1 \) for all 0 \leq k < n\_components

Read more in the User Guide.

**Parameters**

- **n_components** [int.] number of dictionary elements to extract
- **alpha** [float.] sparsity controlling parameter
- **n_iter** [int.] total number of iterations to perform
- **fit_algorithm** [['lars', 'cd']] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- **n_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **batch_size** [int.] number of samples in each mini-batch
- **shuffle** [bool.] whether to shuffle the samples before forming batches
- **dict_init** [array of shape (n\_components, n\_features),] initial value of the dictionary for warm restart scenarios
- **transform_algorithm** [['lasso\_lars', 'lasso\_cd', 'lars', 'omp', 'threshold']] Algorithm used to transform the data. lars: uses the least angle regression method (linear_model.lars_path) lasso\_lars: uses Lars to compute the Lasso solution lasso\_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso\_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate
the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary \* X’

**transform_n_nonzero_coefs** [int, 0.1 * n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case.

**transform_alpha** [float, 1. by default] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.

**verbose** [bool, optional (default: False)] To control the verbosity of the procedure.

**split_sign** [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**positive_code** [bool] Whether to enforce positivity when finding the code.

   New in version 0.20.

**positive_dict** [bool] Whether to enforce positivity when finding the dictionary.

   New in version 0.20.

**transform_max_iter** [int, optional (default=1000)] Maximum number of iterations to perform if algorithm='lasso_cd' or lasso_lars.

   New in version 0.22.

**Attributes**

- **components_** [array, [n_components, n_features]] components extracted from the data
- **inner_stats_** [tuple of (A, B) ndarrays] Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid losing the history of the evolution, but they shouldn’t have any use for the end user. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix
- **n_iter_** [int] Number of iterations run.
- **iter_offset_** [int] The number of iteration on data batches that has been performed before.
- **random_state_** [RandomState] RandomState instance that is generated either from a seed, the random number generator or by np.random.

MiniBatchSparsePCA

Notes

References:

Methods

```python
fit(self, X[, y]) Fit the model from data in X.
fit_transform(self, X[, y]) Fit to data, then transform it.
get_params(self[, deep]) Get parameters for this estimator.
partial_fit(self, X[, y, iter_offset]) Updates the model using the data in X as a mini-batch.
set_params(self, **params) Set the parameters of this estimator.
transform(self, X) Encode the data as a sparse combination of the dictionary atoms.
```

```python
__init__(self, n_components=None, alpha=1, n_iter=1000, fit_algorithm='lasso', n_jobs=None, batch_size=3, shuffle=True, dict_init=None, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, verbose=False, split_sign=False, random_state=None, positive_code=False, positive_dict=False, transform_max_iter=1000)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y=None)
Fit the model from data in X.

Parameters
X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
y [Ignored]

Returns
self [object] Returns the instance itself.
```

```python
fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.
**fit_params [dict] Additional fit parameters.

Returns
X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.
```
**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit** *(self, X, y=None, iter_offset=None)*

Updates the model using the data in X as a mini-batch.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [Ignored]
- **iter_offset** [integer, optional] The number of iteration on data batches that has been performed before this call to partial_fit. This is optional: if no number is passed, the memory of the object is used.

**Returns**

- **self** [object] Returns the instance itself.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

**Parameters**

- **X** [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

- **X_new** [array, shape (n_samples, n_components)] Transformed data

**Examples using** `sklearn.decomposition.MiniBatchDictionaryLearning`

- *Image denoising using dictionary learning*
- *Faces dataset decompositions*
**7.8.8 sklearn.decomposition.MiniBatchSparsePCA**

```python
class sklearn.decomposition.MiniBatchSparsePCA (n_components=None, alpha=1, ridge_alpha=0.01, n_iter=100, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=None, method='lars', random_state=None, normalize_components='deprecated')
```

Mini-batch Sparse Principal Components Analysis

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the **User Guide**.

**Parameters**

- `n_components` [int,] number of sparse atoms to extract
- `alpha` [int,] Sparsity controlling parameter. Higher values lead to sparser components.
- `ridge_alpha` [float,] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
- `n_iter` [int,] number of iterations to perform for each mini batch
- `callback` [callable or None, optional (default: None)] callable that gets invoked every five iterations
- `batch_size` [int,] the number of features to take in each mini batch
- `verbose` [int] Controls the verbosity; the higher, the more messages. Defaults to 0.
- `shuffle` [boolean,] whether to shuffle the data before splitting it in batches
- `n_jobs` [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- `method` [‘lars’, ‘cd’] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- `random_state` [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- `normalize_components` [‘deprecated’] This parameter does not have any effect. The components are always normalized.

New in version 0.20.

Deprecation since version 0.22: `normalize_components` is deprecated in 0.22 and will be removed in 0.24.

**Attributes**

- `components_` [array, [n_components, n_features]] Sparse components extracted from the data.
- `n_iter_` [int] Number of iterations run.
- `mean_` [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to X.mean(axis=0).

PCA
SparsePCA
DictionaryLearning

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import MiniBatchSparsePCA

>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = MiniBatchSparsePCA(n_components=5, batch_size=50,
...                                 random_state=0)
>>> transformer.fit(X)
MiniBatchSparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
>>> np.mean(transformer.components_ == 0)
0.94
```

Methods

- **fit**(self, X[, y]) Fit the model from data in X.
- **fit_transform**(self, X[, y]) Fit to data, then transform it.
- **get_params**(self[, deep]) Get parameters for this estimator.
- **set_params**(self, **params) Set the parameters of this estimator.
- **transform**(self, X) Least Squares projection of the data onto the sparse components.

```python
__init__(self, n_components=None, alpha=1, ridge_alpha=0.01, n_iter=100, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=None, method='lars', random_state=None, normalize_components='deprecated')
```

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y=None)
Fit the model from data in X.

- **Parameters**
  - X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
  - y [Ignored]

- **Returns**
  - self [object] Returns the instance itself.

**fit_transform**(self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the ridge_alpha parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new array, shape (n_samples, n_components) Transformed data.

Examples using sklearn.decomposition.MiniBatchSparsePCA

- Faces dataset decompositions
Non-Negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

\[
0.5 \times ||X - WH||_{\text{Fro}}^2 \\
+ \alpha \times 1_{\text{ll}} \times ||\text{vec}(W)||_1 \\
+ \alpha \times 1_{\text{ll}} \times ||\text{vec}(H)||_1 \\
+ 0.5 \times \alpha \times (1 - 1_{\text{ll}}) \times ||W||_{\text{Fro}}^2 \\
+ 0.5 \times \alpha \times (1 - 1_{\text{ll}}) \times ||H||_{\text{Fro}}^2
\]

Where:

\[
||A||_{\text{Fro}}^2 = \sum_{i,j} A_{ij}^2 \quad (\text{Frobenius norm}) \\
||\text{vec}(A)||_1 = \sum_{i,j} \text{abs}(A_{ij}) \quad (\text{Elementwise L1 norm})
\]

For multiplicative-update (‘mu’) solver, the Frobenius norm (0.5 * ||X - WH||_{\text{Fro}}^2) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H.

Read more in the User Guide.

**Parameters**

- **n_components** [int or None] Number of components, if n_components is not set all features are kept.

- **init** [None | ‘random’ | ‘nndsvd’ | ‘nndsvda’ | ‘nndsvdar’ | ‘custom’] Method used to initialize the procedure. Default: None. Valid options:
  - None: ‘nndsvd’ if n_components <= min(n_samples, n_features), otherwise random.
  - ‘random’: non-negative random matrices, scaled with: \(\sqrt{X.\text{mean}() / n_{\text{components}}}\)
  - ‘nndsvd’: Nonnegative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
  - ‘nndsvda’: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
  - ‘nndsvdar’: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
  - ‘custom’: use custom matrices W and H

- **solver** [‘cd’ | ‘mu’] Numerical solver to use: ‘cd’ is a Coordinate Descent solver. ‘mu’ is a Multiplicative Update solver.

  New in version 0.17: Coordinate Descent solver.

  New in version 0.19: Multiplicative Update solver.
**beta_loss** [float or string, default ‘frobenius’] String must be in {‘frobenius’, ‘kullback-leibler’, ‘itakura-saito’}. Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

**max_iter** [integer, default: 200] Maximum number of iterations before timing out.

**random_state** [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**alpha** [double, default: 0.] Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: **alpha** used in the Coordinate Descent solver.

**l1_ratio** [double, default: 0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter **l1_ratio** used in the Coordinate Descent solver.

**verbose** [bool, default=False] Whether to be verbose.

**shuffle** [boolean, default: False] If true, randomize the order of coordinates in the CD solver.

New in version 0.17: **shuffle** parameter used in the Coordinate Descent solver.

**Attributes**

**components_** [array, [n_components, n_features]] Factorization matrix, sometimes called ‘dictionary’.

**n_components_** [integer] The number of components. It is same as the n_components parameter if it was given. Otherwise, it will be same as the number of features.

**reconstruction_err_** [number] Frobenius norm of the matrix difference, or beta-divergence, between the training data X and the reconstructed data WH from the fitted model.

**n_iter_** [int] Actual number of iterations.

**References**

Examples

```python
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_
```

**init** (self, n_components=None, init=None, solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, random_state=None, alpha=0.0, l1_ratio=0.0, verbose=0, shuffle=False)

Initialize self. See help(type(self)) for accurate signature.

**fit** (self, X, y=None, **params)

Learn a NMF model for the data X.

Parameters

- `X` ([array-like, sparse matrix], shape (n_samples, n_features)) Data matrix to be decomposed
- `y` [Ignored]

Returns

- `self`

**fit_transform** (self, X, y=None, W=None, H=None)

Learn a NMF model for the data X and returns the transformed data.

This is more efficient than calling fit followed by transform.

Parameters

- `X` ([array-like, sparse matrix], shape (n_samples, n_features)) Data matrix to be decomposed
- `y` [Ignored]
- `W` [array-like, shape (n_samples, n_components)] If init=’custom’, it is used as initial guess for the solution.
- `H` [array-like, shape (n_components, n_features)] If init=’custom’, it is used as initial guess for the solution.

Returns

- `W` [array, shape (n_samples, n_components)] Transformed data.
get_params(self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(self, W)
Transform data back to its original space.

Parameters

W [[array-like, sparse matrix], shape (n_samples, n_components)] Transformed data matrix

Returns

X [[array-like, sparse matrix], shape (n_samples, n_features)] Data matrix of original shape

New in version 0.18: ..

set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(self, X)
Transform the data X according to the fitted NMF model

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Data matrix to be transformed by the model

Returns

W [array, shape (n_samples, n_components)] Transformed data

Examples using sklearn.decomposition.NMF

• Beta-divergence loss functions
• Faces dataset decompositions
• Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
• Selecting dimensionality reduction with Pipeline and GridSearchCV
**7.8.10 sklearn.decomposition.PCA**

```python
class sklearn.decomposition.PCA(n_components=None, copy=True, whiten=False, svd_solver='auto', tol=0.0, iterated_power='auto', random_state=None)
```

Principal component analysis (PCA).

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower-dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the scipy.sparse.linalg ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See TruncatedSVD for an alternative with sparse data.

Read more in the User Guide.

**Parameters**

- `n_components` [int, float, None or str] Number of components to keep. if `n_components` is not set all components are kept:

  ```plaintext
  n_components == min(n_samples, n_features)
  ```

  If `n_components == 'mle' and svd_solver == 'full'`, Minka’s MLE is used to guess the dimension. Use of `n_components == 'mle'` will interpret `svd_solver == 'auto'` as `svd_solver == 'full'`.

  If `0 < n_components < 1` and `svd_solver == 'full'`, select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by `n_components`.

  If `svd_solver == 'arpack'`, the number of components must be strictly less than the minimum of `n_features` and `n_samples`.

  Hence, the None case results in:

  ```plaintext
  n_components == min(n_samples, n_features) - 1
  ```

- `copy` [bool, default=True] If False, data passed to fit are overwritten and running `fit(X).transform(X)` will not yield the expected results, use `fit_transform(X)` instead.

- `whiten` [bool, optional (default False)] When True (False by default) the components_ vectors are multiplied by the square root of `n_samples` and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

  Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

- `svd_solver` [str {‘auto’, ‘full’, ‘arpack’, ‘randomized’}]  
  
  If `auto`: The solver is selected by a default policy based on `X.shape` and `n_components`: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient ‘randomized’ method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.

  If `full`: run exact full SVD calling the standard LAPACK solver via `scipy.linalg.svd` and select the components by postprocessing.
If arpack : run SVD truncated to n_components calling ARPACK solver via scipy.sparse.linalg.svds. It requires strictly 0 < n_components < min(X.shape)

If randomized : run randomized SVD by the method of Halko et al.

New in version 0.18.0.

tol [float >= 0, optional (default .0)] Tolerance for singular values computed by svd_solver == ‘arpack’.

New in version 0.18.0.

iterated_power [int >= 0, or ‘auto’, (default ‘auto’)] Number of iterations for the power method computed by svd_solver == ‘randomized’.

New in version 0.18.0.

random_state [int, RandomState instance or None, optional (default None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when svd_solver == ‘arpack’ or ‘randomized’.

New in version 0.18.0.

Attributes

components_ [array, shape (n_components, n_features)] Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by explained_variance_.

explained_variance_ [array, shape (n_components,)] The amount of variance explained by each of the selected components.

Equal to n_components largest eigenvalues of the covariance matrix of X.

New in version 0.18.

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components.

If n_components is not set then all components are stored and the sum of the ratios is equal to 1.0.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

New in version 0.19.

mean_ [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to X.mean(axis=0).

n_components_ [int] The estimated number of components. When n_components is set to ‘mle’ or a number between 0 and 1 (with svd_solver == ‘full’) this number is estimated from input data. Otherwise it equals the parameter n_components, or the lesser value of n_features and n_samples if n_components is None.

n_features_ [int] Number of features in the training data.

n_samples_ [int] Number of samples in the training data.

noise_variance_ [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See “Pattern Recognition and Machine Learning” by C.
Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf. It is required
to compute the estimated data covariance and score samples.

Equal to the average of \((\min(n\_features, n\_samples) - n\_components)\) smallest eigenvalues
of the covariance matrix of X.

## Methods

- `fit(self, X[, y])`: Fit the model with X.
- `fit_transform(self, X[, y])`: Fit the model with X and apply the dimensionality reduction on X.
- `get_covariance(self)`: Compute data covariance with the generative model.
- `get_params(self[, deep])`: Get parameters for this estimator.
- `get_precision(self)`: Compute data precision matrix with the generative model.
- `inverse_transform(self, X)`: Transform data back to its original space.
- `score(self, X[, y])`: Return the average log-likelihood of all samples.
- `score_samples(self, X)`: Return the log-likelihood of each sample.
- `set_params(self, **params)`: Set the parameters of this estimator.
- `transform(self, X)`: Apply dimensionality reduction to X.

### __init__

```python
__init__(self, n_components=None, copy=True, whiten=False, svd_solver='auto', tol=0.0, iterated_power='auto', random_state=None)
```

Initialize self. See help(type(self)) for accurate signature.

### fit

```python
fit(self, X, y=None)
```

Fit the model with X.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [None] Ignored variable.

**Returns**

- `self` [object] Returns the instance itself.

### fit_transform

```python
fit_transform(self, X, y=None)
```

Fit the model with X and apply the dimensionality reduction on X.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [None] Ignored variable.

**Returns**

- `X_new` [array-like, shape (n_samples, n_components)] Transformed values.

### Notes

This method returns a Fortran-ordered array. To convert it to a C-ordered array, use ‘np.ascontiguousarray’.
get_covariance(self)
Compute data covariance with the generative model.

cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)
where S**2 contains the explained variances, and sigma2 contains the noise variances.

Returns

cov [array, shape=(n_features, n_features)] Estimated covariance of data.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

generate(self)
Generate data from the GMM.

Parameters

X [array-like] The number of samples.

Y [array-like] The number of components.

Returns

X [array-like, shape=(n_samples, n_features)] Samples generated from the model.

Notes

If whitening is enabled, generate will return data in the whitened space. To get the
data back in the original space, use inverse_transform.

score(self, X, y=None)
Return the average log-likelihood of all samples.

See. “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or

Parameters

X [array-like, shape=(n_samples, n_features)] The data.

y [None] Ignored variable.

Returns

ll [float] Average log-likelihood of the samples under the current model.
score_samples (self, X)
Return the log-likelihood of each sample.

Parameters
X [array, shape(n_samples, n_features)] The data.

Returns
ll [array, shape (n_samples,)] Log-likelihood of each sample under the current model.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

transform (self, X)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

Parameters
X [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns
X_new [array-like, shape (n_samples, n_components)]

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X) # doctest: +SKIP
```

### 7.8.11 sklearn.decomposition.SparsePCA

```python
class sklearn.decomposition.SparsePCA(n_components=None, alpha=1, ridge_alpha=0.01, max_iter=1000, tol=1e-08, method='lars', n_jobs=None, U_init=None, V_init=None, verbose=False, random_state=None, normalize_components='deprecated')
```

Sparse Principal Components Analysis (SparsePCA)

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the User Guide.

**Parameters**

- `n_components`  [int]  Number of sparse atoms to extract.
- `alpha`  [float]  Sparsity controlling parameter. Higher values lead to sparser components.
- `ridge_alpha`  [float]  Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
- `max_iter`  [int]  Maximum number of iterations to perform.
- `tol`  [float]  Tolerance for the stopping condition.
method  ['lars', 'cd']  lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path)  cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs  [int or None, optional (default=None)]  Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

U_init  [array of shape (n_samples, n_components),]  Initial values for the loadings for warm restart scenarios.

V_init  [array of shape (n_components, n_features),]  Initial values for the components for warm restart scenarios.

verbose  [int]  Controls the verbosity; the higher, the more messages. Defaults to 0.

random_state  [int, RandomState instance or None, optional (default=None)]  If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

normalize_components  ['deprecated']  This parameter does not have any effect. The components are always normalized.

New in version 0.20.

Deprecated since version 0.22: normalize_components is deprecated in 0.22 and will be removed in 0.24.

Attributes

components_  [array, [n_components, n_features]]  Sparse components extracted from the data.

error_  [array]  Vector of errors at each iteration.

n_iter_  [int]  Number of iterations run.

mean_  [array, shape (n_features,)]  Per-feature empirical mean, estimated from the training set. Equal to X.mean(axis=0).

MiniBatchSparsePCA

DictionaryLearning

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import SparsePCA
>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = SparsePCA(n_components=5, random_state=0)
>>> transformer.fit(X)
SparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
```
```python
>>> np.mean(transformer.components_ == 0)
0.9666...
```

**Methods**

- `fit(self, X[, y])` Fit the model from data in X.
- `fit_transform(self, X[, y])` Fit to data, then transform it.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Least Squares projection of the data onto the sparse components.

```python
__init__(self, n_components=None, alpha=1, ridge_alpha=0.01, max_iter=1000, tol=1e-08, method='lars', n_jobs=None, U_init=None, V_init=None, verbose=False, random_state=None, normalize_components='deprecated')
```

Initialize self. See help(type(self)) for accurate signature.

- `fit (self, X, y=None)` Fit the model from data in X.

  **Parameters**
  
  - `X` [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
  
  - `y` [Ignored]

  **Returns**
  
  - `self` [object] Returns the instance itself.

- `fit_transform (self, X, y=None, **fit_params)` Fit to data, then transform it.

  Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

  **Parameters**
  
  - `X` [numpy array of shape [n_samples, n_features]] Training set.
  
  - `y` [numpy array of shape [n_samples]] Target values.

  ****fit_params [dict] Additional fit parameters.

  **Returns**
  
  - `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.

- `get_params (self, deep=True)` Get parameters for this estimator.

  **Parameters**
  
  - `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

  **Returns**
  
  - `params` [mapping of string to any] Parameter names mapped to their values.
set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

transform (self, X)
Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the ridge_alpha parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters
X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns
X_new array, shape (n_samples, n_components) Transformed data.

7.8.12 sklearn.decomposition.SparseCoder
class sklearn.decomposition.SparseCoder (dictionary, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, split_sign=False, n_jobs=None, positive_code=False, transform_max_iter=1000)

Sparse coding
Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array code such that:

\[ X \approx code \times \text{dictionary} \]

Read more in the User Guide.

Parameters

dictionary [array, [n_components, n_features]] The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.

transform_algorithm [‘lasso_lars’, ‘lasso_cd’, ‘lars’, ‘omp’, ‘threshold’], default=’omp’ Algorithm used to transform the data: lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars
will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary $* X$.

**transform_n_nonzero_coefs** [int, default=0.1*n_features] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case.

**transform_alpha** [float, default=1.] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.

**split_sign** [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**n_jobs** [int or None, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**positive_code** [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

**transform_max_iter** [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or lasso_lars.

New in version 0.22.

**Attributes**

**components_** [array, [n_components, n_features]] The unchanged dictionary atoms

__init__(self, dictionary, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, split_sign=False, n_jobs=None, positive_code=False, transform_max_iter=1000)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Do nothing and return the estimator unchanged
This method is just there to implement the usual API and hence work in pipelines.

Parameters
X [Ignored]
y [Ignored]

Returns
self [object] Returns the object itself

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.
y [nump array of shape [n_samples]] Target values.
**fit_params [dict] Additional fit parameters.

Returns
X_new [nump array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

transform (self, X)
Encode the data as a sparse combination of the dictionary atoms.
Coding method is determined by the object parameter transform_algorithm.
Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data

Examples using sklearn.decomposition.SparseCoder

• Sparse coding with a precomputed dictionary

7.8.13 sklearn.decomposition.TruncatedSVD

class sklearn.decomposition.TruncatedSVD(n_components=2, algorithm='randomized', n_iter=5, random_state=None, tol=0.0)

Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition (SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with scipy.sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in sklearn.feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a “naive” algorithm that uses ARPACK as an eigensolver on (X * X.T) or (X.T * X), whichever is more efficient.

Read more in the User Guide.

Parameters

n_components [int, default = 2] Desired dimensionality of output data. Must be strictly less than the number of features. The default value is useful for visualisation. For LSA, a value of 100 is recommended.

algorithm [string, default = “randomized”] SVD solver to use. Either “arpack” for the ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or “randomized” for the randomized algorithm due to Halko (2009).

n_iter [int, optional (default 5)] Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in sklearn.utils.extmath.randomized_svd to handle sparse matrices that may have large slowly decaying spectrum.

random_state [int, RandomState instance or None, optional, default = None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

components_ [array, shape (n_components, n_features)]

explained_variance_ [array, shape (n_components,)] The variance of the training samples transformed by a projection to each component.
explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

See also:

PCA

Notes

SVD suffers from a problem called “sign indeterminacy”, which means the sign of the components_ and the output from transform depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

References

Examples

```python
>>> from sklearn.decomposition import TruncatedSVD
>>> from scipy.sparse import random as sparse_random
>>> from sklearn.random_projection import sparse_random_matrix
>>> X = sparse_random(100, 100, density=0.01, format='csr', seed=42)
>>> svd = TruncatedSVD(n_components=5, n_iter=7, random_state=42)
>>> svd.fit(X)
>>> print(svd.explained_variance_ratio_)
[0.0646... 0.0633... 0.0639... 0.0535... 0.0406...]
>>> print(svd.explained_variance_ratio_.sum())
0.286...
>>> print(svd.singular_values_)
[1.553... 1.512... 1.510... 1.370... 1.199...]
```

Methods

- `fit(self, X[, y])` Fit LSI model on training data X.
- `fit_transform(self, X[, y])` Fit LSI model to X and perform dimensionality reduction on X.
- `get_params(self[, deep])` Get parameters for this estimator.
- `inverse_transform(self, X)` Transform X back to its original space.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Perform dimensionality reduction on X.

```
__init__(self, n_components=2, algorithm='randomized', n_iter=5, random_state=None, tol=0.0)
```

Initialize self. See help(type(self)) for accurate signature.
**fit** *(self, X, y=None)*

Fit LSI model on training data X.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) Training data.
- **y** [Ignored]

**Returns**

- **self** [object] Returns the transformer object.

**fit_transform** *(self, X, y=None)*

Fit LSI model to X and perform dimensionality reduction on X.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) Training data.
- **y** [Ignored]

**Returns**

- **X_new** [array, shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** *(self, X)*

Transform X back to its original space.

Returns an array X_original whose transform would be X.

**Parameters**

- **X** [array-like, shape (n_samples, n_components)] New data.

**Returns**

- **X_original** [array, shape (n_samples, n_features)] Note that this is always a dense array.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.
transform(self, X)
Perform dimensionality reduction on X.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] New data.

Returns

X_new [array, shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

Examples using sklearn.decomposition.TruncatedSVD

- Hashing feature transformation using Totally Random Trees
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
- Column Transformer with Heterogeneous Data Sources
- Clustering text documents using k-means

decomposition.dict_learning(X, n_components, ...)
Solves a dictionary learning matrix factorization problem.
decomposition.dict_learning_online(X[, ...])
Solves a dictionary learning matrix factorization problem online.
decomposition.fastica(X[, n_components, ...])
Perform Fast Independent Component Analysis.
decomposition.non_negative_factorization(X)
Compute Non-negative Matrix Factorization (NMF)
decomposition.sparse_encode(X, dictionary[, ...])
Sparse coding

7.8.14 sklearn.decomposition.dict_learning

sklearn.decomposition.dict_learning(X, n_components, alpha, max_iter=100, tol=1e-08, method='lars', n_jobs=None, dict_init=None, code_init=None, callback=None, verbose=False, random_state=None, return_n_iter=False, positive_dict=False, positive_code=False, method_max_iter=1000)
Solves a dictionary learning matrix factorization problem.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

\[(U^*, V^*) = \arg\min_{(U,V)} 0.5 \| X - U V \|_2^2 + \alpha \| U \|_1\]

with \| V_k \|_2 = 1 for all 0 <= k < n_components

where V is the dictionary and U is the sparse code.

Read more in the User Guide.

Parameters

X [array of shape (n_samples, n_features)] Data matrix.
n_components [int,] Number of dictionary atoms to extract.
alpha [int,] Sparsity controlling parameter.
max_iter [int,] Maximum number of iterations to perform.

tol [float,] Tolerance for the stopping condition.

method [\{‘lars’, ‘cd’\}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

dict_init [array of shape (n_components, n_features),] Initial value for the dictionary for warm restart scenarios.

code_init [array of shape (n_samples, n_components),] Initial value for the sparse code for warm restart scenarios.

callback [callable or None, optional (default: None)] Callable that gets invoked every five iterations

verbose [bool, optional (default: False)] To control the verbosity of the procedure.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

return_n_iter [bool] Whether or not to return the number of iterations.

positive_dict [bool] Whether to enforce positivity when finding the dictionary.

positive_code [bool] Whether to enforce positivity when finding the code.

method_max_iter [int, optional (default=1000)] Maximum number of iterations to perform.

Returns

code [array of shape (n_samples, n_components)] The sparse code factor in the matrix factorization.

dictionary [array of shape (n_components, n_features),] The dictionary factor in the matrix factorization.

errors [array] Vector of errors at each iteration.

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

7.8.15 `sklearn.decomposition.dict_learning_online`

`sklearn.decomposition.dict_learning_online(X, n_components=2, alpha=1, n_iter=100, return_code=True, dict_init=None, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=None, method='lars', iter_offset=0, random_state=None, return_inner_stats=False, inner_stats=None, return_n_iter=False, positive_dict=False, positive_code=False, method_max_iter=1000)`

Solves a dictionary learning matrix factorization problem online.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

\[(U^*, V^*) = \underset{(U,V)}{\text{argmin}} \ 0.5 \ || X - U V ||_2^2 + \alpha \ || U ||_1 \]

where V is the dictionary and U is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the User Guide.

Parameters

- **X**: array of shape (n_samples, n_features) Data matrix.
- **n_components**: int Number of dictionary atoms to extract.
- **alpha**: float Sparsity controlling parameter.
- **n_iter**: int Number of mini-batch iterations to perform.
- **return_code**: bool Whether to also return the code U or just the dictionary V.
- **dict_init**: array of shape (n_components, n_features) Initial value for the dictionary for warm restart scenarios.
- **callback**: callable or None, optional (default: None) Callable that gets invoked every five iterations.
- **batch_size**: int The number of samples to take in each batch.
- **verbose**: bool, optional (default: False) To control the verbosity of the procedure.
- **shuffle**: bool, optional Whether to shuffle the data before splitting it in batches.
- **n_jobs**: int or None, optional (default=None) Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **method**: {'lars', 'cd'} lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- **iter_offset**: int, default 0 Number of previous iterations completed on the dictionary used for initialization.
- **random_state**: int, RandomState instance or None, optional (default=None) If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
return_inner_stats [boolean, optional] Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If return_inner_stats is True, return_code is ignored.

inner_stats [tuple of (A, B) ndarrays] Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid losing the history of the evolution. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix.

return_n_iter [bool] Whether or not to return the number of iterations.

positive_dict [bool] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

positive_code [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

method_max_iter [int, optional (default=1000)] Maximum number of iterations to perform when solving the lasso problem.

New in version 0.22.

Returns

code [array of shape (n_samples, n_components),] the sparse code (only returned if return_code=True)

dictionary [array of shape (n_components, n_features),] the solutions to the dictionary learning problem

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

7.8.16 sklearn.decomposition.fastica

sklearn.decomposition.fastica(X, n_components=None, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None, return_X_mean=False, compute_sources=True, return_n_iter=False)

Perform Fast Independent Component Analysis.

Read more in the User Guide.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

n_components [int, optional] Number of components to extract. If None no dimension reduction is performed.
algorithm [{‘parallel’, ‘deflation’}, optional] Apply a parallel or deflational FASTICA algorithm.

whiten [boolean, optional] If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n_components will be ignored.

fun [string or function, optional. Default: ‘logcosh’] The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. The derivative should be averaged along its last dimension. Example:

```python
def my_g(x):
    return x ** 3, np.mean(3 * x ** 2, axis=-1)
```

fun_args [dictionary, optional] Arguments to send to the functional form. If empty or None and if fun=’logcosh’, fun_args will take value {‘alpha’ : 1.0}

max_iter [int, optional] Maximum number of iterations to perform.

tol [float, optional] A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.

w_init [(n_components, n_components) array, optional] Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.’s is used.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

return_X_mean [bool, optional] If True, X_mean is returned too.

compute_sources [bool, optional] If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

K [array, shape (n_components, n_features) | None.] If whiten is ‘True’, K is the pre-whitening matrix that projects data onto the first n_components principal components. If whiten is ‘False’, K is ‘None’.

W [array, shape (n_components, n_components)] The square matrix that unmixes the data after whitening. The mixing matrix is the pseudo-inverse of matrix \( W K \) if K is not None, else it is the inverse of W.

S [array, shape (n_samples, n_components) | None] Estimated source matrix

X_mean [array, shape (n_features, )] The mean over features. Returned only if return_X_mean is True.

n_iter [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return_n_iter is set to True.

Notes

The data matrix X is considered to be a linear combination of non-Gaussian (independent) components i.e. X = AS where columns of S contain the independent components and A is a linear mixing matrix. In short ICA
attempts to un-mix the data by estimating an un-mixing matrix W where \`S = W K X.\` While FastICA was proposed to estimate as many sources as features, it is possible to estimate less by setting n_components < n_features. It this case K is not a square matrix and the estimated A is the pseudo-inverse of \( W K \).

This implementation was originally made for data of shape [n_features, n_samples]. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

### 7.8.17 sklearn.decomposition.non_negative_factorization

`sklearn.decomposition.non_negative_factorization(X, W=None, H=None, n_components=None, init='warn', update_H=True, update_W=True, solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, alpha=0.0, l1_ratio=0.0, regularization=None, verbose=0, shuffle=False)`

Compute Non-negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

\[
0.5 * ||X - WH||_{\text{Fro}}^2 + \alpha * l1_ratio * ||\text{vec}(W)||_1 \\
+ \alpha * l1_ratio * ||\text{vec}(H)||_1 \\
+ 0.5 * \alpha * (1 - l1_ratio) * ||W||_{\text{Fro}}^2 \\
+ 0.5 * \alpha * (1 - l1_ratio) * ||H||_{\text{Fro}}^2
\]

Where:

\[
||A||_{\text{Fro}}^2 = \sum_{i,j} A_{ij}^2 \quad \text{(Frobenius norm)} \\
||\text{vec}(A)||_1 = \sum_{i,j} \text{abs}(A_{ij}) \quad \text{(Elementwise L1 norm)}
\]

For multiplicative-update (‘mu’) solver, the Frobenius norm \(0.5 * \|X - WH\|_{\text{Fro}}^2\) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H. If H is given and update_H=False, it solves for W only.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Constant matrix.
- **W** [array-like, shape (n_samples, n_components)] If init='custom', it is used as initial guess for the solution.
- **H** [array-like, shape (n_components, n_features)] If init='custom', it is used as initial guess for the solution. If update_H=False, it is used as a constant, to solve for W only.
- **n_components** [integer] Number of components, if n_components is not set all features are kept.
- **init** [None | ‘random’ | ‘nndsvd’ | ‘nndsvda’ | ‘nndsvdA’ | ‘custom’] Method used to initialize the procedure. Default: ‘random’. 

7.8. sklearn.decomposition: Matrix Decomposition
The default value will change from ‘random’ to None in version 0.23 to make it consistent with decomposition.NMF.

Valid options:

- None: ‘nndsvd’ if n_components < n_features, otherwise ‘random’.
- **random**: non-negative random matrices, scaled with: \( \sqrt{\text{X.mean()} / \text{n_components}} \)
- **nndsvd**: Nonnegative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
- **nndsvda**: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
- **nndsvdar**: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSV Da for when sparsity is not desired)
- **custom**: use custom matrices W and H

update_H [boolean, default: True] Set to True, both W and H will be estimated from initial guesses. Set to False, only W will be estimated.

solver ['cd' | 'mu'] Numerical solver to use:

- **cd** is a Coordinate Descent solver that uses Fast Hierarchical Alternating Least Squares (Fast HALS).
- **mu** is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.
New in version 0.19: Multiplicative Update solver.

beta_loss [float or string, default ‘frobenius’] String must be in {‘frobenius’, ‘kullback-leibler’, ‘itakura-saito’}. Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

max_iter [integer, default: 200] Maximum number of iterations before timing out.

alpha [double, default: 0.] Constant that multiplies the regularization terms.

l1_ratio [double, default: 0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

regularization ['both' | 'components' | 'transformation' | None] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

random_state [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

verbose [integer, default: 0] The verbosity level.

shuffle [boolean, default: False] If true, randomize the order of coordinates in the CD solver.
Returns

W [array-like, shape (n_samples, n_components)] Solution to the non-negative least squares problem.

H [array-like, shape (n_components, n_features)] Solution to the non-negative least squares problem.

n_iter [int] Actual number of iterations.

References

Examples

```python
>>> import numpy as np
>>> X = np.array([[1,1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import non_negative_factorization
>>> W, H, n_iter = non_negative_factorization(X, n_components=2,... init='random', random_state=0)
```

7.8.18 sklearn.decomposition.sparse_encode

sklearn.decomposition.sparse_encode(X, dictionary, gram=None, cov=None, algorithm='lasso_lars', n_nonzero_coefs=None, alpha=None, copy_cov=True, init=None, max_iter=1000, n_jobs=None, check_input=True, verbose=0, positive=False)

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array code such that:

```
X ~= code * dictionary
```

Read more in the User Guide.

Parameters

- X [array of shape (n_samples, n_features)] Data matrix
- dictionary [array of shape (n_components, n_features)] The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.
- gram [array, shape=(n_components, n_components)] Precomputed Gram matrix, dictionary * dictionary’
- cov [array, shape=(n_components, n_samples)] Precomputed covariance, dictionary’ * X
algorithm (['lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold']) lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X

n_nonzero_coefs [int, 0.1 * n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case.

alpha [float, 1. by default] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.

copy_cov [boolean, optional] Whether to copy the precomputed covariance matrix; if False, it may be overwritten.

init [array of shape (n_samples, n_components)] Initialization value of the sparse codes. Only used if algorithm='lasso_cd'.

max_iter [int, 1000 by default] Maximum number of iterations to perform if algorithm='lasso_cd' or lasso_lars.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

check_input [boolean, optional] If False, the input arrays X and dictionary will not be checked.

verbose [int, optional] Controls the verbosity; the higher, the more messages. Defaults to 0.

positive [boolean, optional] Whether to enforce positivity when finding the encoding.

New in version 0.20.

Returns
code [array of shape (n_samples, n_components)] The sparse codes

sklearn.linear_model.Lasso
SparseCoder

7.9 sklearn.discriminant_analysis: Discriminant Analysis

Linear Discriminant Analysis and Quadratic Discriminant Analysis

User guide: See the Linear and Quadratic Discriminant Analysis section for further details.
Linear Discriminant Analysis
A classifier with a linear decision boundary, generated by fitting class conditional densities to the data and using Bayes’ rule.

The model fits a Gaussian density to each class, assuming that all classes share the same covariance matrix.

The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discriminative directions.

New in version 0.17: `LinearDiscriminantAnalysis`.

Read more in the `User Guide`.

**Parameters**

- **solver** [string, optional]

  Solver to use, possible values:
  - ‘svd’: Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
  - ‘lsqr’: Least squares solution, can be combined with shrinkage.
  - ‘eigen’: Eigenvalue decomposition, can be combined with shrinkage.

- **shrinkage** [string or float, optional]

  Shrinkage parameter, possible values:
  - None: no shrinkage (default).
  - ‘auto’: automatic shrinkage using the Ledoit-Wolf lemma.
  - float between 0 and 1: fixed shrinkage parameter.

  Note that shrinkage works only with ‘lsqr’ and ‘eigen’ solvers.

- **priors** [array, optional, shape (n_classes,)] Class priors.

- **n_components** [int, optional (default=None)] Number of components (<= min(n_classes - 1, n_features)) for dimensionality reduction. If None, will be set to min(n_classes - 1, n_features).

  New in version 0.17.

- **store_covariance** [bool, optional] Additionally compute class covariance matrix (default False), used only in ‘svd’ solver.

### 7.9. `sklearn.discriminant_analysis.LinearDiscriminantAnalysis`

class sklearn.discriminant_analysis.LinearDiscriminantAnalysis(solver='svd',
shrinkage=None,
priors=None,
n_components=None,
store_covariance=False,
tol=0.0001)
tol [float, optional, (default 1.0e-4)] Threshold used for rank estimation in SVD solver.

Attributes

- **coeff_** [array, shape (n_features,) or (n_classes, n_features)] Weight vector(s).
- **intercept_** [array, shape (n_classes,)] Intercept term.
- **covariance_** [array-like, shape (n_features, n_features)] Covariance matrix (shared by all classes).
- **explained_variance_ratio_** [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If n_components is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.
- **means_** [array-like, shape (n_classes, n_features)] Class means.
- **priors_** [array-like, shape (n_classes,)] Class priors (sum to 1).
- **scalings_** [array-like, shape (rank, n_classes - 1)] Scaling of the features in the space spanned by the class centroids.
- **xbar_** [array-like, shape (n_features,)] Overall mean.
- **classes_** [array-like, shape (n_classes,)] Unique class labels.

See also:

- **sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis** Quadratic Discriminant Analysis

Notes

The default solver is ‘svd’. It can perform both classification and transform, and it does not rely on the calculation of the covariance matrix. This can be an advantage in situations where the number of features is large. However, the ‘svd’ solver cannot be used with shrinkage.

The ‘lsqr’ solver is an efficient algorithm that only works for classification. It supports shrinkage.

The ‘eigen’ solver is based on the optimization of the between class scatter to within class scatter ratio. It can be used for both classification and transform, and it supports shrinkage. However, the ‘eigen’ solver needs to compute the covariance matrix, so it might not be suitable for situations with a high number of features.

Examples

```python
>>> import numpy as np
>>> from sklearn.discriminant_analysis import LinearDiscriminantAnalysis
>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = LinearDiscriminantAnalysis()
>>> clf.fit(X, y)
LinearDiscriminantAnalysis()
>>> print(clf.predict([[0.8, 1]]))
[1]
```

__init__(self, solver='svd', shrinkage=None, priors=None, n_components=None, store_covariance=False, tol=0.0001)

Initialize self. See help(type(self)) for accurate signature.

decision_function(self, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

- X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit (self, X, y)

Fit LinearDiscriminantAnalysis model according to the given training data and parameters.

Changed in version 0.19: store_c covariance has been moved to main constructor.

Changed in version 0.19: tol has been moved to main constructor.

Parameters

- X [array-like, shape (n_samples, n_features)] Training data.
- y [array, shape (n_samples,)] Target values.

fit_transform (self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns
get_params (self, deep=True)
Get parameters for this estimator.

Parameters
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- **params** [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict class labels for samples in X.

Parameters
- **X** [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
- **C** [array, shape [n_samples]] Predicted class label per sample.

predict_log_proba (self, X)
Estimate log probability.

Parameters
- **X** [array-like, shape (n_samples, n_features)] Input data.

Returns
- **C** [array, shape (n_samples, n_classes)] Estimated log probabilities.

predict_proba (self, X)
Estimate probability.

Parameters
- **X** [array-like, shape (n_samples, n_features)] Input data.

Returns
- **C** [array, shape (n_samples, n_classes)] Estimated probabilities.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns
- **score** [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform** (self, X)

Project data to maximize class separation.

**Parameters**

X [array-like, shape (n_samples, n_features)] Input data.

**Returns**

X_new [array, shape (n_samples, n_components)] Transformed data.

Examples using sklearn.discriminant_analysis.LinearDiscriminantAnalysis

- Normal and Shrinkage Linear Discriminant Analysis for classification
- Linear and Quadratic Discriminant Analysis with covariance ellipsoid
- Comparison of LDA and PCA 2D projection of Iris dataset
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
- Dimensionality Reduction with Neighborhood Components Analysis

7.9.2 sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

**class** sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

Quadratic Discriminant Analysis

A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Bayes’ rule.

The model fits a Gaussian density to each class.

New in version 0.17: QuadraticDiscriminantAnalysis

Read more in the User Guide.

**Parameters**

**priors** [array, optional, shape = [n_classes]] Priors on classes

**reg_param** [float, optional] Regularizes the covariance estimate as 

\[(1 - \text{reg\_param}) \Sigma + \text{reg\_param} \cdot \text{np.eye}(n\_features)\]

**store_covariance** [boolean] If True the covariance matrices are computed and stored in the self.covariance_ attribute.

New in version 0.17.
tol [float, optional, default 1.0e-4] Threshold used for rank estimation.

New in version 0.17.

Attributes

covariance_ [list of array-like of shape (n_features, n_features)] Covariance matrices of each
class.

means_ [array-like of shape (n_classes, n_features)] Class means.

priors_ [array-like of shape (n_classes)] Class priors (sum to 1).

rotations_ [list of arrays] For each class k an array of shape [n_features, n_k], with n_k =
min(n_features, number of elements in class k) It is the rotation of the
Gaussian distribution, i.e. its principal axis.

scalings_ [list of arrays] For each class k an array of shape [n_k]. It contains the scaling of the
Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate
system.

classes_ [array-like, shape (n_classes,)] Unique class labels.

sklearn.discriminant_analysis.LinearDiscriminantAnalysis Linear Discriminant
Analysis

Examples

```python
>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
QuadraticDiscriminantAnalysis()
>>> print(clf.predict([[0.8, -1]]))
[1]
```

Methods

decision_function(self, X) Apply decision function to an array of samples.

fit(self, X, y) Fit the model according to the given training data and
parameters.

get_params(self[, deep]) Get parameters for this estimator.

predict(self, X) Perform classification on an array of test vectors X.

predict_log_proba(self, X) Return posterior probabilities of classification.

predict_proba(self, X) Return posterior probabilities of classification.

score(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and
labels.

set_params(self, **params) Set the parameters of this estimator.

__init__(self, priors=None, reg_param=0.0, store_covariance=False, tol=0.0001)
Initialize self. See help(type(self)) for accurate signature.
**decision_function** *(self, X)*

Apply decision function to an array of samples.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

**Returns**

- C [ndarray of shape (n_samples,) or (n_samples, n_classes)] Decision function values related to each class, per sample. In the two-class case, the shape is [n_samples,], giving the log likelihood ratio of the positive class.

**fit** *(self, X, y)*

Fit the model according to the given training data and parameters.

Changed in version 0.19: *store_covariances* has been moved to main constructor as *store_covariance*

Changed in version 0.19: *tol* has been moved to main constructor.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- y [array, shape = [n_samples]] Target values (integers)

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [mapping of string to any] Parameter names mapped to their values.

**predict** *(self, X)*

Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

**Parameters**

- X [array-like of shape (n_samples, n_features)]

**Returns**

- C [ndarray of shape (n_samples,)]

**predict_log_proba** *(self, X)*

Return posterior probabilities of classification.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

**Returns**

- C [ndarray of shape (n_samples, n_classes)] Posterior log-probabilities of classification per class.
predict_proba \( (self, X) \)
Return posterior probabilities of classification.

Parameters

\( X \) [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns

\( C \) [ndarray of shape (n_samples, n_classes)] Posterior probabilities of classification per class.

score \( (self, X, y, sample\_weight=None) \)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

\( X \) [array-like of shape (n_samples, n_features)] Test samples.
\( y \) [array-like of shape (n_samples,) or (n_samples, n_outputs)]: True labels for X.
\( sample\_weight \) [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params \( (self, **params) \)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

- Classifier comparison
- Linear and Quadratic Discriminant Analysis with covariance ellipsoid

7.10 sklearn.dummy: Dummy estimators

User guide: See the Metrics and scoring: quantifying the quality of predictions section for further details.

dummy.DummyClassifier([strategy, ...])
DummyClassifier is a classifier that makes predictions using simple rules.
dummy.DummyRegressor([strategy, constant, ...])
DummyRegressor is a regressor that makes predictions using simple rules.
**7.10.1 sklearn.dummy.DummyClassifier**

```python
class sklearn.dummy.DummyClassifier(strategy='warn', random_state=None, constant=None)
```

DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the *User Guide*.

New in version 0.13.

**Parameters**

- **strategy** [str, default=“stratified”] Strategy to use to generate predictions.
  - “stratified”: generates predictions by respecting the training set’s class distribution.
  - “most_frequent”: always predicts the most frequent label in the training set.
  - “prior”: always predicts the class that maximizes the class prior (like “most_frequent”) and `predict_proba` returns the class prior.
  - “uniform”: generates predictions uniformly at random.
  - “constant”: always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class

Changed in version 0.22: The default value of `strategy` will change to “prior” in version 0.24. Starting from version 0.22, a warning will be raised if `strategy` is not explicitly set.

New in version 0.17: Dummy Classifier now supports prior fitting strategy using parameter `prior`.

- **random_state** [int, RandomState instance or None, optional, default=None] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

- **constant** [int or str or array-like of shape (n_outputs,)] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

**Attributes**

- **classes_** [array or list of array of shape (n_classes,)] Class labels for each output.
- **n_classes_** [array or list of array of shape (n_classes,)] Number of label for each output.
- **class_prior_** [array or list of array of shape (n_classes,)] Probability of each class for each output.
- **n_outputs_** [int.] Number of outputs.
- **sparse_output_** [bool.] True if the array returned from `predict` is to be in sparse CSC format. Is automatically set to True if the input `y` is passed in sparse format.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.dummy import DummyClassifier
>>> X = np.array([-1, 1, 1, 1])
```
```python
>>> y = np.array([0, 1, 1, 1])
>>> dummy_clf = DummyClassifier(strategy="most_frequent")
>>> dummy_clf.fit(X, y)
DummyClassifier(strategy='most_frequent')
>>> dummy_clf.predict(X)
array([1, 1, 1, 1])
>>> dummy_clf.score(X, y)
0.75
```

### __init__

```
__init__(self, strategy='warn', random_state=None, constant=None)
```

Initialize self. See help(type(self)) for accurate signature.

### fit

```
fitted(X, y, sample_weight=None)
```

Fit the random classifier.

#### Parameters

- **X** ([array-like, object with finite length or shape]) Training data, requires length = n_samples
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

#### Returns

- **self** [object]

### get_params

```
get_params(self, deep=True)
```

Get parameters for this estimator.

#### Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

### predict

```
predict(self, X)
```

Perform classification on test vectors X.

#### Parameters

- **X** [array-like, object with finite length or shape] Test vectors X.
X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Predicted target values for X.

predict_log_proba (self, X)
Return log probability estimates for the test vectors X.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns

P [array-like or list of array-like of shape (n_samples, n_classes)] Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

predict_proba (self, X)
Return probability estimates for the test vectors X.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns

P [array-like or list of array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.

score (self, X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [{array-like, None}] Test samples with shape = (n_samples, n_features) or None. Passing None as test samples gives the same result as passing real test samples, since DummyClassifier operates independently of the sampled observations.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.
Returns

self [object] Estimator instance.

7.10.2 sklearn.dummy.DummyRegressor

class sklearn.dummy.DummyRegressor (strategy='mean', constant=None, quantile=None)

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

Read more in the User Guide.

New in version 0.13.

Parameters

strategy [str] Strategy to use to generate predictions.

• “mean”: always predicts the mean of the training set
• “median”: always predicts the median of the training set
• “quantile”: always predicts a specified quantile of the training set, provided with the quantile parameter.
• “constant”: always predicts a constant value that is provided by the user.

constant [int or float or array-like of shape (n_outputs,)] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

quantile [float in [0.0, 1.0]] The quantile to predict using the “quantile” strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

Attributes

constant_ [array, shape (1, n_outputs)] Mean or median or quantile of the training targets or constant value given by the user.

n_outputs_ [int] Number of outputs.

Examples

```python
>>> import numpy as np
>>> from sklearn.dummy import DummyRegressor
>>> X = np.array([1.0, 2.0, 3.0, 4.0])
>>> y = np.array([2.0, 3.0, 5.0, 10.0])
>>> dummy_regr = DummyRegressor(strategy="mean")
>>> dummy_regr.fit(X, y)
DummyRegressor()
>>> dummy_regr.predict(X)
array([5., 5., 5., 5.])
>>> dummy_regr.score(X, y)
0.0
```

Methods
The code snippet above defines a function for fitting a random regressor. The function `fit` takes training data `X` and target values `y` as input. The function returns the fitted regressor.

The `get_params` function retrieves the parameters of the regressor. The `predict` function performs classification on test vectors `X` and returns the predicted target values. The `score` function returns the coefficient of determination $R^2$ of the prediction.

The `__init__` function initializes the regressor and sets parameters such as strategy, constant, and quantile.

The `set_params` function sets the parameters of the regressor.

The `score` function returns the coefficient of determination $R^2$ of the prediction. The score is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares and $v$ is the total sum of squares. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.
Parameters

X [[array-like, None]] Test samples with shape = (n_samples, n_features) or None. For some estimators this may be a precomputed kernel matrix instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator. Passing None as test samples gives the same result as passing real test samples, since DummyRegressor operates independently of the sampled observations.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.11 sklearn.ensemble: Ensemble Methods

The sklearn.ensemble module includes ensemble-based methods for classification, regression and anomaly detection.

### 7.11.1 `sklearn.ensemble.AdaBoostClassifier`

**class sklearn.ensemble.AdaBoostClassifier**

```python
(base_estimator=None, n_estimators=50,
 learning_rate=1.0, algorithm='SAMME.R',
 random_state=None)
```

An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

This class implements the algorithm known as AdaBoost-SAMME [2].

Read more in the *User Guide*.

New in version 0.14.

**Parameters**

- **base_estimator** [object, optional (default=None)] The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper classes_ and n_classes_ attributes. If None, then the base estimator is `DecisionTreeClassifier(max_depth=1)`.

- **n_estimators** [int, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

- **learning_rate** [float, optional (default=1.0)] Learning rate shrinks the contribution of each classifier by learning_rate. There is a trade-off between learning_rate and n_estimators.

- **algorithm** [‘SAMME’, ‘SAMME.R’, optional (default=’SAMME.R’)] If ‘SAMME.R’ then use the SAMME.R real boosting algorithm. base_estimator must support calculation of class probabilities. If ‘SAMME’ then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Attributes**

- **base_estimator_** [estimator] The base estimator from which the ensemble is grown.
The collection of fitted sub-estimators.

classes_ [array of shape (n_classes,)] The classes labels.

n_classes_ [int] The number of classes.

estimator_weights_ [array of floats] Weights for each estimator in the boosted ensemble.

estimator_errors_ [array of floats] Classification error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] Return the feature importances (the higher, the more important the feature).

See also:

AdaBoostRegressor An AdaBoost regressor that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction.

GradientBoostingClassifier GB builds an additive model in a forward stage-wise fashion. Regression trees are fit on the negative gradient of the binomial or multinomial deviance loss function. Binary classification is a special case where only a single regression tree is induced.

sklearn.tree.DecisionTreeClassifier A non-parametric supervised learning method used for classification. Creates a model that predicts the value of a target variable by learning simple decision rules inferred from the data features.

</table>

**__init__** (self, base_estimator=None, n_estimators=50, learning_rate=1.0, algorithm='SAMME.R', random_state=None)
Initialize self. See help(type(self)) for accurate signature.

**decision_function** (self, X)
Compute the decision function of X.

Parameters

- **X** (array-like, sparse matrix) of shape (n_samples, n_features) The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

- **score** (array, shape = [n_samples, k]) The decision function of the input samples. The order of outputs is the same of that of the classes_ attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in classes_, respectively.

**property feature_importances_**
Return the feature importances (the higher, the more important the feature).

Returns

- **feature_importances_** (ndarray of shape (n_features,)) The feature importances.

**fit** (self, X, y, sample_weight=None)
Build a boosted classifier from the training set (X, y).

Parameters

- **X** (array-like, sparse matrix) of shape (n_samples, n_features) The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

- **y** (array-like of shape (n_samples,)) The target values (class labels).

- **sample_weight** (array-like of shape (n_samples,), default=None) Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns

**get_params** (self, deep=True)
Get parameters for this estimator.
Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

**predict** *(self, X)*

Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

y [ndarray of shape (n_samples,)] The predicted classes.

**predict_log_proba** *(self, X)*

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

**predict_proba** *(self, X)*

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

**score** *(self, X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

staged_decision_function (self, X)
Compute decision function of X for each boosting iteration.
This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

Parameters
X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.
Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted
to CSR.

Yields
score [generator of array, shape = [n_samples, k]] The decision function of the input sam-
plies. The order of outputs is the same of that of the classes_ attribute. Binary classification
is a special cases with k == 1, otherwise k==n_classes. For binary classification,
values closer to -1 or 1 mean more like the first or second class in classes_, respectively.

staged_predict (self, X)
Return staged predictions for X.
The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in
the ensemble.
This generator method yields the ensemble prediction after each iteration of boosting and therefore allows
monitoring, such as to determine the prediction on a test set after each boost.

Parameters
X [array-like of shape (n_samples, n_features)] The input samples. Sparse matrix can be
CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields
y [generator of array, shape = [n_samples]] The predicted classes.

staged_predict_proba (self, X)
Predict class probabilities for X.
The predicted class probabilities of an input sample is computed as the weighted mean predicted class
probabilities of the classifiers in the ensemble.
This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Yields**

- **p** [generator of array, shape = [n_samples]] The class probabilities of the input samples. The order of outputs is the same of that of the `classes_` attribute.

**staged_score** *(self, X, y, sample_weight=None)*

Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

- **y** [array-like of shape (n_samples,)] Labels for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Yields**

- **z** [float]

**Examples using sklearn.ensemble.AdaBoostClassifier**

- Classifier comparison
- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees
- Discrete versus Real AdaBoost
- Plot the decision surfaces of ensembles of trees on the iris dataset

**7.11.2 sklearn.ensemble.AdaBoostRegressor**

class sklearn.ensemble.AdaBoostRegressor *(base_estimator=None, n_estimators=50, learning_rate=1.0, loss='linear', random_state=None)*

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the *User Guide*.

New in version 0.14.
Parameters

base_estimator [object, optional (default=None)] The base estimator from which the boosted ensemble is built. If None, then the base estimator is DecisionTreeRegressor(max_depth=3).

n_estimators [integer, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

learning_rate [float, optional (default=1.0)] Learning rate shrinks the contribution of each regressor by learning_rate. There is a trade-off between learning_rate and n_estimators.

loss [{'linear', 'square', 'exponential'}, optional (default='linear')] The loss function to use when updating the weights after each boosting iteration.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

estimators_ [list of classifiers] The collection of fitted sub-estimators.

estimator_weights_ [array of floats] Weights for each estimator in the boosted ensemble.

estimator_errors_ [array of floats] Regression error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] Return the feature importances (the higher, the more important the feature).

__init__(self, base_estimator=None, n_estimators=50, learning_rate=1.0, loss='linear', random_state=None)
Initialize self. See help(type(self)) for accurate signature.

property feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns

feature_importances_ [ndarray of shape (n_features,)] The feature importances.

fit (self, X, y, sample_weight=None)
Build a boosted regressor from the training set (X, y).

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] The target values (real numbers).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns

self [object]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
**predict**(self, X)

Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

- **y** [ndarray of shape (n_samples,)] The predicted regression values.

**score**(self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as \((1 - u/v)\), where \(u\) is the residual sum of squares \(((y_{\text{true}} - y_{\text{pred}})^2).\text{sum()}\) and \(v\) is the total sum of squares \(((y_{\text{true}} - y_{\text{true}.\text{mean}})^2).\text{sum()}\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with $r2\_score$. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call $r2\_score$ directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

**set_params**(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.
**staged_predict** *(self, X)*
Return staged predictions for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.

**Yields**

- **y** [generator of array, shape = [n_samples]] The predicted regression values.

**staged_score** *(self, X, y, sample_weight=None)*
Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.
  
  Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

- **y** [array-like of shape (n_samples,)] Labels for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Yields**

- **z** [float]

Examples using `sklearn.ensemble.AdaBoostRegressor`

- Decision Tree Regression with AdaBoost

### 7.11.3 sklearn.ensemble.BaggingClassifier

**class** `sklearn.ensemble.BaggingClassifier` *(base_estimator=None, n_estimators=10, max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=None, random_state=None, verbose=0)*

A Bagging classifier.

A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [Rb1846455d0e5-1]. If samples are drawn with replacement, then the method is known as Bagging [Rb1846455d0e5-2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces.
Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches.

Read more in the User Guide.

New in version 0.15.

**Parameters**

- **base_estimator** [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.
- **n_estimators** [int, optional (default=10)] The number of base estimators in the ensemble.
- **max_samples** [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.
  - If int, then draw `max_samples` samples.
  - If float, then draw `max_samples * X.shape[0]` samples.
- **max_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.
  - If int, then draw `max_features` features.
  - If float, then draw `max_features * X.shape[1]` features.
- **bootstrap** [boolean, optional (default=True)] Whether samples are drawn with replacement. If False, sampling without replacement is performed.
- **bootstrap_features** [boolean, optional (default=False)] Whether features are drawn with replacement.
- **oob_score** [bool, optional (default=False)] Whether to use out-of-bag samples to estimate the generalization error.
- **warm_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See the Glossary.

New in version 0.17: warm_start constructor parameter.

- **n_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for both `fit` and `predict`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.
- **verbose** [int, optional (default=0)] Controls the verbosity when fitting and predicting.

**Attributes**

- **base_estimator_** [estimator] The base estimator from which the ensemble is grown.
- **n_features_** [int] The number of features when `fit` is performed.
- **estimators_** [list of estimators] The collection of fitted base estimators.
- **estimators_samples_** [list of arrays] The subset of drawn samples for each base estimator.
- **estimators_features_** [list of arrays] The subset of drawn features for each base estimator.
classes_ [array of shape (n_classes,)] The classes labels.

n_classes_ [int or list] The number of classes.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

oob_decision_function_ [array of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

Examples

```python
>>> from sklearn.svm import SVC
>>> from sklearn.ensemble import BaggingClassifier
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_samples=100, n_features=4, ...
... n_informative=2, n_redundant=0, ...
... random_state=0, shuffle=False)

>>> clf = BaggingClassifier(base_estimator=SVC(), ...
... n_estimators=10, random_state=0).fit(X, y)

>>> clf.predict([[0, 0, 0, 0]])
array([1])
```

Methods

- **decision_function**(self, X) Average of the decision functions of the base classifiers.
- **fit**(self, X, y[, sample_weight]) Build a Bagging ensemble of estimators from the training
- **get_params**(self[, deep]) Get parameters for this estimator.
- **predict**(self, X) Predict class for X.
- **predict_log_proba**(self, X) Predict class log-probabilities for X.
- **predict_proba**(self, X) Predict class probabilities for X.
- **score**(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.
- **set_params**(self, **params) Set the parameters of this estimator.

- **__init__**(self, base_estimator=None, n_estimators=10, max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=None, random_state=None, verbose=0)

  Initialize self. See help(type(self)) for accurate signature.

- **decision_function**(self, X)

  Average of the decision functions of the base classifiers.

  Parameters
X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

score [array, shape = [n_samples, k]] The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute classes_. Regression and binary classification are special cases with k == 1, otherwise k==n_classes.

property estimators_samples_

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit (self, X, y, sample_weight=None)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns

self [object]

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)

Predict class for X.

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a predict_proba method, then it resorts to voting.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

y [ndarray of shape (n_samples,)] The predicted classes.
**predict_log_proba** (*self, X*)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **p** [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict_proba** (*self, X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities of the base estimators in the ensemble. If base estimators do not implement a `predict_proba` method, then it resorts to voting and the predicted class probabilities of an input sample represents the proportion of estimators predicting each class.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **p** [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*self, X, y, sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (*self, **params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.
A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [R4d113ba76fc0-1]. If samples are drawn with replacement, then the method is known as Bagging [R4d113ba76fc0-2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [R4d113ba76fc0-3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [R4d113ba76fc0-4].

Read more in the User Guide.

New in version 0.15.

Parameters

- **base_estimator** [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

- **n_estimators** [int, optional (default=10)] The number of base estimators in the ensemble.

- **max_samples** [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.
  - If int, then draw max_samples samples.
  - If float, then draw max_samples * X.shape[0] samples.

- **max_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.
  - If int, then draw max_features features.
  - If float, then draw max_features * X.shape[1] features.

- **bootstrap** [boolean, optional (default=True)] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

- **bootstrap_features** [boolean, optional (default=False)] Whether features are drawn with replacement.

- **oob_score** [bool] Whether to use out-of-bag samples to estimate the generalization error.

- **warm_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See the Glossary.

- **n_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for both fit and predict. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

verbose [int, optional (default=0)] Controls the verbosity when fitting and predicting.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

n_features_ [int] The number of features when `fit` is performed.

estimators_ [list of estimators] The collection of fitted sub-estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.

estimators_features_ [list of arrays] The subset of drawn features for each base estimator.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when `oob_score` is True.

oob_prediction_ [ndarray of shape (n_samples,)] Prediction computed with out-of-bag estimate on the training set. If `n_estimators` is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_prediction_` might contain NaN. This attribute exists only when `oob_score` is True.

[R4d113ba76fc0-1], [R4d113ba76fc0-2], [R4d113ba76fc0-3], [R4d113ba76fc0-4]

Examples

```python
>>> from sklearn.svm import SVR
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_samples=100, n_features=4,
...                        n_informative=2, n_targets=1,
...                        random_state=0, shuffle=False)

>>> regr = BaggingRegressor(base_estimator=SVR(),
...                          n_estimators=10, random_state=0).fit(X, y)

>>> regr.predict([[0, 0, 0, 0]])
array([-2.8720...])
```

Methods

- `fit(self, X, y[, sample_weight])`: Build a Bagging ensemble of estimators from the training
- `get_params(self[, deep])`: Get parameters for this estimator.
- `predict(self, X)`: Predict regression target for X.
- `score(self, X, y[, sample_weight])`: Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)`: Set the parameters of this estimator.
__init__(self, base_estimator=None, n_estimators=10, max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=None, random_state=None, verbose=0)

Initialize self. See help(type(self)) for accurate signature.

property estimators_samples_

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit (self, X, y, sample_weight=None)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns

self [object]

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)

Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

y [ndarray of shape (n_samples,)] The predicted values.

score (self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares ($(y_{true} - y_{pred})^2$).sum() and $v$ is the total sum of squares ($(y_{true} - y_{true.mean()})^2$).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set_params**(self, **params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**Examples using sklearn.ensemble.BaggingRegressor**

- Single estimator versus bagging: bias-variance decomposition

**7.11.5 sklearn.ensemble.IsolationForest**

**class sklearn.ensemble.IsolationForest**(n_estimators=100, max_samples='auto', contamination='auto', max_features=1.0, bootstrap=False, n_jobs=None, behaviour='deprecated', random_state=None, verbose=0, warm_start=False)

Isolation Forest Algorithm.

Return the anomaly score of each sample using the IsolationForest algorithm.

The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.
Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the User Guide.

New in version 0.18.

Parameters

n_estimators [int, optional (default=100)] The number of base estimators in the ensemble.

max_samples [int or float, optional (default="auto")]

The number of samples to draw from X to train each base estimator.

- If int, then draw max_samples samples.
- If float, then draw max_samples * X.shape[0] samples.
- If "auto", then max_samples=min(256, n_samples).

If max_samples is larger than the number of samples provided, all samples will be used for all trees (no sampling).

contamination ['auto' or float, optional (default='auto')] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the scores of the samples.

- If 'auto', the threshold is determined as in the original paper.
- If float, the contamination should be in the range [0, 0.5].

Changed in version 0.22: The default value of contamination changed from 0.1 to 'auto'.

max_features [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw max_features features.
- If float, then draw max_features * X.shape[1] features.

bootstrap [bool, optional (default=False)] If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for both fit and predict. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

behaviour [str, default='deprecated'] This parameter has no effect, is deprecated, and will be removed.

New in version 0.20: behaviour is added in 0.20 for back-compatibility purpose.

Deprecated since version 0.20: behaviour='old' is deprecated in 0.20 and will not be possible in 0.22.

Deprecated since version 0.22: behaviour parameter is deprecated in 0.22 and removed in 0.24.
random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

verbose [int, optional (default=0)] Controls the verbosity of the tree building process.

warm_start [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

New in version 0.21.

Attributes

estimators_ [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.

max_samples_ [integer] The actual number of samples

offset_ [float] Offset used to define the decision function from the raw scores. We have the relation: decision_function = score_samples - offset_. offset_ is defined as follows. When the contamination parameter is set to “auto”, the offset is equal to -0.5 as the scores of inliers are close to 0 and the scores of outliers are close to -1. When a contamination parameter different than “auto” is provided, the offset is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training.

See also:

sklearn.covariance.EllipticEnvelope An object for detecting outliers in a Gaussian distributed dataset.

sklearn.svm.OneClassSVM Unsupervised Outlier Detection. Estimate the support of a high-dimensional distribution. The implementation is based on libsvm.

sklearn.neighbors.LocalOutlierFactor Unsupervised Outlier Detection using Local Outlier Factor (LOF).

Notes

The implementation is based on an ensemble of ExtraTreeRegressor. The maximum depth of each tree is set to \(\text{ceil}(\log_2(n))\) where \(n\) is the number of samples used to build the tree (see (Liu et al., 2008) for more details).

Examples

```python
>>> from sklearn.ensemble import IsolationForest
>>> X = [[-1.1], [0.3], [0.5], [100]]
>>> clf = IsolationForest(random_state=0).fit(X)
(continues on next page)```
Methods

---

**decision_function**(*self, X*)

Average anomaly score of X of the base classifiers.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

- **scores** [array, shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

**property estimators_samples_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit** (*self, X, y=None, sample_weight=None*)

Fit estimator.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.
y [Ignored] Not used, present for API consistency by convention.

```
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.
```

Returns

```
self [object] Fitted estimator.
```

**fit_predict** *(self, X, y=None)*

Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

Parameters

```
X [ndarray, shape (n_samples, n_features)] Input data.
y [Ignored] Not used, present for API consistency by convention.
```

Returns

```
y [ndarray, shape (n_samples,)] 1 for inliers, -1 for outliers.
```

**get_params** *(self, deep=True)*

Get parameters for this estimator.

Parameters

```
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
```

Returns

```
params [mapping of string to any] Parameter names mapped to their values.
```

**predict** *(self, X)*

Predict if a particular sample is an outlier or not.

Parameters

```
X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.
```

Returns

```
is_inlier [array, shape (n_samples,)] For each observation, tells whether or not (+1 or -1) it should be considered as an inlier according to the fitted model.
```

**score_samples** *(self, X)*

Opposite of the anomaly score defined in the original paper.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

Parameters

```
X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples.
```

Returns

```
scores [array, shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal.
```

1816 Chapter 7. API Reference
`set_params`(*self*, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

`self` [object] Estimator instance.

Examples using `sklearn.ensemble.IsolationForest`

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- IsolationForest example

### 7.11.6 `sklearn.ensemble.RandomTreesEmbedding`

```python
class sklearn.ensemble.RandomTreesEmbedding(n_estimators=100, max_depth=5, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, sparse_output=True, n_jobs=None, random_state=None, verbose=0, warm_start=False)
```

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a binary coding with as many ones as there are trees in the forest.

The dimensionality of the resulting representation is `n_out <= n_estimators * max_leaf_nodes`. If `max_leaf_nodes == None`, the number of leaf nodes is at most `n_estimators * 2 ** max_depth`.

Read more in the `User Guide`.

**Parameters**

**n_estimators** [integer, optional (default=10)] Number of trees in the forest.

Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

**max_depth** [integer, optional (default=5)] The maximum depth of each tree. If `None`, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min_samples_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
• If float, then \( \text{min\_samples\_split} \) is a fraction and \( \text{ceil}(\text{min\_samples\_split} \times n\_samples) \) is the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

\textbf{min\_samples\_leaf} [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least \( \text{min\_samples\_leaf} \) training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

• If int, then consider \( \text{min\_samples\_leaf} \) as the minimum number.

• If float, then \( \text{min\_samples\_leaf} \) is a fraction and \( \text{ceil}(\text{min\_samples\_leaf} \times n\_samples) \) is the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

\textbf{min\_weight\_fraction\_leaf} [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

\textbf{max\_leaf\_nodes} [int or None, optional (default=None)] Grow trees with \( \text{max\_leaf\_nodes} \) in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

\textbf{min\_impurity\_decrease} [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right\_impurity} - \frac{N_{t,L}}{N_t} \times \text{left\_impurity})
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

\( N, N_t, N_{t,R} \) and \( N_{t,L} \) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

\textbf{min\_impurity\_split} [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: \textbf{min\_impurity\_split} has been deprecated in favor of \textbf{min\_impurity\_decrease} in 0.19. The default value of \textbf{min\_impurity\_split} will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use \textbf{min\_impurity\_decrease} instead.

\textbf{sparse\_output} [bool, optional (default=True)] Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

\textbf{n\_jobs} [int or None, optional (default=None)] The number of jobs to run in parallel. \textit{fit}, \textit{transform}, \textit{decision\_path} and \textit{apply} are all parallelized over the trees. None means 1 unless in a \textit{joblib.parallel\_backend} context. -1 means using all processors. See \textit{Glossary} for more details.

\textbf{random\_state} [int, RandomState instance or None, optional (default=None)] Controls the generation of the random \( y \) used to fit the trees and the draw of the splits for each feature at the trees’ nodes. See \textit{Glossary} for details.

\textbf{verbose} [int, optional (default=0)] Controls the verbosity when fitting and predicting.
**warm_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

**Attributes**

- **estimators_** [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

**References**

[R6e47e53bacbd-1], [R6e47e53bacbd-2]

**Methods**

- **apply**(self, X) Apply trees in the forest to X, return leaf indices.
- **decision_path**(self, X) Return the decision path in the forest.
- **fit**(self, X[, y, sample_weight]) Fit estimator.
- **fit_transform**(self, X[, y, sample_weight]) Fit estimator and transform dataset.
- **get_params**(self[, deep]) Get parameters for this estimator.
- **set_params**(self, **params) Set the parameters of this estimator.
- **transform**(self, X) Transform dataset.

- **init** (self, n_estimators=100, max_depth=5, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, sparse_output=True, n_jobs=None, random_state=None, verbose=0, warm_start=False) Initialize self. See help(type(self)) for accurate signature.

- **apply**(self, X) Apply trees in the forest to X, return leaf indices.

**Parameters**

- **X** [array-like or sparse matrix] of shape (n_samples, n_features) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **X_leaves** [array_like, shape = [n_samples, n_estimators]] For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

- **decision_path**(self, X) Return the decision path in the forest.

**New in version 0.18.**

- **Parameters**

**X** [array-like or sparse matrix] of shape (n_samples, n_features) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **indicator** [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.
n_nodes_ptr [array of size (n_estimators + 1, )] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

property feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns

feature_importances_ [array, shape = [n_features]] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit (self, X, y=None, sample_weight=None)

Fit estimator.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] The input samples. Use dtype=np.float32 for maximum efficiency. Sparse matrices are also supported, use sparse csc_matrix for maximum efficiency.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

self [object]

fit_transform (self, X, y=None, sample_weight=None)

Fit estimator and transform dataset.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Input data used to build forests. Use dtype=np.float32 for maximum efficiency.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

X_transformed [sparse matrix, shape=(n_samples, n_out)] Transformed dataset.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
set_params(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict]** Estimator parameters.

Returns

self [object] Estimator instance.

transform(self, X)

Transform dataset.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Input data to be transformed. Use dtype=np.float32 for maximum efficiency. Sparse matrices are also supported, use sparse csr_matrix for maximum efficiency.

Returns

X_transformed [sparse matrix, shape=(n_samples, n_out)] Transformed dataset.

- Hashing feature transformation using Totally Random Trees
- Feature transformations with ensembles of trees
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

7.11.7 sklearn.ensemble.StackingClassifier

class sklearn.ensemble.StackingClassifier(estimators, final_estimator=None, cv=None, stack_method=’auto’, n_jobs=None, passthrough=False, verbose=0)

Stack of estimators with a final classifier.

Stacked generalization consists in stacking the output of individual estimator and use a classifier to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that estimators_ are fitted on the full X while final_estimator_ is trained using cross-validated predictions of the base estimators using cross_val_predict.

New in version 0.22.

Read more in the User Guide.

Parameters

estimators [list of (str, estimator)] Base estimators which will be stacked together. Each element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An estimator can be set to ‘drop’ using set_params.

final_estimator [estimator, default=None] A classifier which will be used to combine the base estimators. The default classifier is a LogisticRegression.
cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in cross_val_predict to train final_estimator. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified) KFold,
- An object to be used as a cross-validation generator,
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Note: A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. cv is not used for model evaluation but for prediction.

stack_method [{'auto', 'predict_proba', 'decision_function', 'predict'}, default='auto'] Methods called for each base estimator. It can be:

- if 'auto', it will try to invoke, for each estimator, 'predict_proba', 'decision_function' or 'predict' in that order.
- otherwise, one of 'predict_proba', 'decision_function' or 'predict'. If the method is not implemented by the estimator, it will raise an error.

n_jobs [int, default=None] The number of jobs to run in parallel all estimators fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

passthrough [bool, default=False] When False, only the predictions of estimators will be used as training data for final_estimator. When True, the final_estimator is trained on the predictions as well as the original training data.

Attributes

estimators_ [list of estimators] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to 'drop', it will not appear in estimators_.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

final_estimator_ [estimator] The classifier which predicts given the output of estimators_.

stack_method_ [list of str] The method used by each base estimator.

Notes

When predict_proba is used by each estimator (i.e. most of the time for stack_method='auto' or specifically for stack_method='predict_proba'), The first column predicted by each estimator will be dropped in the case of a binary classification problem. Indeed, both feature will be perfectly collinear.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.svm import LinearSVC
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.ensemble import StackingClassifier

>>> X, y = load_iris(return_X_y=True)
>>> estimators = [
...    ('rf', RandomForestClassifier(n_estimators=10, random_state=42)),
...    ('svr', make_pipeline(StandardScaler(), LinearSVC(random_state=42)))
... ]
>>> clf = StackingClassifier(
...    estimators=estimators, final_estimator=LogisticRegression()
... )
>>> from sklearn.model_selection import train_test_split

>>> X_train, X_test, y_train, y_test = train_test_split(
...    X, y, stratify=y, random_state=42
... )
>>> clf.fit(X_train, y_train).score(X_test, y_test)
0.9...
```

Methods

```python
decision_function(self, X) Predict decision function for samples in X using final_estimator_.decision_function.
fit(self, X, y[, sample_weight]) Fit the estimators.
fit_transform(self, X[, y]) Fit to data, then transform it.
get_params(self[, deep]) Get the parameters of an estimator from the ensemble.
predict(self, X[, \*\*predict_params]) Predict target for X.
predict_proba(self, X) Predict class probabilities for X using final_estimator_.predict_proba.
score(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.
set_params(self, \*\*params) Set the parameters of an estimator from the ensemble.
transform(self, X) Return class labels or probabilities for X for each estimator.

__init__(self, estimators, final_estimator=None, cv=None, stack_method='auto', n_jobs=None, passthrough=False, verbose=0) Initialize self. See help(type(self)) for accurate signature.

decision_function (self, X) Predict decision function for samples in X using final_estimator_.decision_function.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
```
Returns

**decisions** [ndarray of shape (n_samples,), (n_samples, n_classes), or (n_samples, n_classes * (n_classes-1) / 2)] The decision function computed the final estimator.

**fit** *(self, X, y, sample_weight=None)*
Fit the estimators.

Parameters

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**y** [array-like of shape (n_samples,)] Target values.

**sample_weight** [array-like of shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

**self** [object]

**fit_transform** *(self, X, y=None, **fit_params)*
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

**X** [numpy array of shape [n_samples, n_features]] Training set.

**y** [numpy array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

Returns

**X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(self, deep=True)*
Get the parameters of an estimator from the ensemble.

Parameters

**deep** [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

**predict** *(self, X, **predict_params)*
Predict target for X.

Parameters

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**predict_params** [dict of str -> obj] Parameters to the predict called by the final_estimator. Note that this may be used to return uncertainties from some estimators with return_std or return_cov. Be aware that it will only accounts for uncertainty in the final estimator.

Returns

**y_pred** [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

**predict_proba** *(self, X)*
Predict class probabilities for X using final_estimator_.predict_proba.
Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

probabilities  [ndarray of shape (n_samples, n_classes) or list of ndarray of shape (n_output,)] The class probabilities of the input samples.

cscore  (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples.
y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params  (self, **params)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params().

Parameters

**params  [keyword arguments] Specific parameters using e.g. set_params(parameter_name=new_value). In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to ‘drop’.

ttransform  (self, X)
Return class labels or probabilities for X for each estimator.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

y_preds  [ndarray of shape (n_samples, n_estimators) or (n_samples, n_classes * n_estimators)] Prediction outputs for each estimator.

Examples using sklearn.ensemble.StackingClassifier

• Release Highlights for scikit-learn 0.22

7.11.8 sklearn.ensemble.StackingRegressor

class sklearn.ensemble.StackingRegressor (estimators, final_estimator=None, cv=None, n_jobs=None, passthrough=False, verbose=0)

Stack of estimators with a final regressor.
Stacked generalization consists in stacking the output of individual estimator and use a regressor to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that `estimators_` are fitted on the full X while `final_estimator_` is trained using cross-validated predictions of the base estimators using `cross_val_predict`.

New in version 0.22.

Read more in the *User Guide*.

**Parameters**

- **estimators** [list of (str, estimator)] Base estimators which will be stacked together. Each element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An estimator can be set to ‘drop’ using `set_params`.

- **final_estimator** [estimator, default=None] A regressor which will be used to combine the base estimators. The default regressor is a `RidgeCV`.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in `cross_val_predict` to train `final_estimator`. Possible inputs for `cv` are:
  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a (Stratified) KFold,
  - An object to be used as a cross-validation generator,
  - An iterable yielding train, test splits.

  For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

  Refer *User Guide* for the various cross-validation strategies that can be used here.

  **Note:** A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. cv is not used for model evaluation but for prediction.

- **n_jobs** [int, default=None] The number of jobs to run in parallel for `fit` of all estimators. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See Glossary for more details.

- **passthrough** [bool, default=False] When False, only the predictions of estimators will be used as training data for `final_estimator`. When True, the `final_estimator` is trained on the predictions as well as the original training data.

**Attributes**

- **estimators_** [list of estimator] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to 'drop', it will not appear in `estimators_`.

- **named_estimators_** [Bunch] Attribute to access any fitted sub-estimators by name.

- **final_estimator_** [estimator] The regressor to stacked the base estimators fitted.

0.3...
```

Methods

```python
fit(self, X, y[, sample_weight]) Fit the estimators.
fit_transform(self, X[, y]) Fit to data, then transform it.
get_params(self[, deep]) Get the parameters of an estimator from the ensemble.
predict(self, X[, y]) Predict target for X.
score(self, X, y[, sample_weight]) Return the coefficient of determination R^2 of the prediction.
set_params(self[, params]) Set the parameters of an estimator from the ensemble.
transform(self, X) Return the predictions for X for each estimator.
```

```python
__init__(self, estimators, final_estimator=None, cv=None, n_jobs=None, passthrough=False, verbose=0)
Initialize self. See help(type(self)) for accurate signature.
```

```python
fit(self, X, y, sample_weight=None)
Fit the estimators.
```

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** (array-like of shape (n_samples,)) Target values.
**sample_weight** | [array-like of shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

**Returns**

self | [object]

**fit_transform** (self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

X | [numpy array of shape [n_samples, n_features]] Training set.

y | [numpy array of shape [n_samples]] Target values.

**fit_params | [dict] Additional fit parameters.

**Returns**

X_new | [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (self, deep=True)

Get the parameters of an estimator from the ensemble.

**Parameters**

deep | [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

**predict** (self, X, **predict_params)

Predict target for X.

**Parameters**

X | [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**predict_params | [dict of str -> obj] Parameters to the predict called by the final_estimator. Note that this may be used to return uncertainties from some estimators with return_std or return_cov. Be aware that it will only accounts for uncertainty in the final estimator.

**Returns**

y_pred | [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

**score** (self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())**2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

X | [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y | [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params  (self, **params)

Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params().

Parameters

**params  [keyword arguments] Specific parameters using e.g. set_params(parameter_name=new_value). In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to 'drop'.

transform  (self, X)

Return the predictions for X for each estimator.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

y_preds  [ndarray of shape (n_samples, n_estimators)] Prediction outputs for each estimator.

Examples using sklearn.ensemble.StackingRegressor

- Combine predictors using stacking

7.11.9 sklearn.ensemble.VotingClassifier

class  sklearn.ensemble.VotingClassifier (estimators, voting='hard', weights=None, n_jobs=None, flatten_transform=True)

Soft Voting/Majority Rule classifier for unfitted estimators.

New in version 0.17.

Read more in the User Guide.

Parameters

estimators  [list of (str, estimator) tuples] Invoking the fit method on the VotingClassifier will fit clones of those original estimators that will be stored in the class attribute self.estimators_. An estimator can be set to 'drop' using set_params.
Deprecation

version 0.22: Using None to drop an estimator is deprecated in 0.22 and support will be dropped in 0.24. Use the string 'drop' instead.

voting [str, {'hard', 'soft'} (default='hard')] If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.

weights [array-like, shape (n_classifiers,), optional (default=None)] Sequence of weights (float or int) to weight the occurrences of predicted class labels (hard voting) or class probabilities before averaging (soft voting). Uses uniform weights if None.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

flatten_transform [bool, optional (default=True)] Affects shape of transform output only when voting='soft'. If voting='soft' and flatten_transform=True, transform method returns matrix with shape (n_samples, n_classifiers * n_classes). If flatten_transform=False, it returns (n_classifiers, n_samples, n_classes).

Attributes

estimators_ [list of classifiers] The collection of fitted sub-estimators as defined in estimators that are not ‘drop’.

named_estimators_ [Bunch object, a dictionary with attribute access] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

classes_ [array-like, shape (n_predictions,)] The classes labels.

See also:

VotingRegressor Prediction voting regressor.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier
>>> clf1 = LogisticRegression(multi_class='multinomial', random_state=1)
>>> clf2 = RandomForestClassifier(n_estimators=50, random_state=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> eclf1 = VotingClassifier(estimators=[
... ('lr', clf1), ('rf', clf2), ('gnb', clf3)], voting='hard')
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2 2]
>>> np.array_equal(eclf1.named_estimators_['lr'].predict(X),
... eclf1.named_estimators_[ 'lr'].predict(X))
True
>>> eclf2 = VotingClassifier(estimators=[
... ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
... voting='soft')
>>> eclf2 = eclf2.fit(X, y)
```
Methods

```
fit(self, X, y[, sample_weight]) Fit the estimators.
fit_transform(self, X[, y]) Fit to data, then transform it.
get_params(self[, deep]) Get the parameters of an estimator from the ensemble.
predict(self, X) Predict class labels for X.
score(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and
parameters.
set_params(self, **params) Set the parameters of an estimator from the ensemble.
transform(self, X) Return class labels or probabilities for X for each estimator.
```

__init__ (self, estimators, voting='hard', weights=None, n_jobs=None, flatten_transform=True)
Initialize self. See help(type(self)) for accurate signature.

```
fit (self, X, y, sample_weight=None)
Fit the estimators.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where
n_samples is the number of samples and n_features is the number of features.

y [array-like, shape (n_samples,)] Target values.

sample_weight [array-like, shape (n_samples,) or None] Sample weights. If None, then
samples are equally weighted. Note that this is supported only if all underlying estimators
support sample weights.

Returns

self [object]

```
fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

 Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.
**fit_params** [dict] Additional fit parameters.

Returns

**X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (self, deep=True)
Get the parameters of an estimator from the ensemble.

Parameters

**deep** [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

**predict** (self, X)
Predict class labels for X.

Parameters

**X** [array-like, sparse matrix], shape (n_samples, n_features)] The input samples.

Returns

**maj** [array-like, shape (n_samples,)] Predicted class labels.

**property predict_proba**
Compute probabilities of possible outcomes for samples in X.

Parameters

**X** [array-like, sparse matrix], shape (n_samples, n_features)] The input samples.

Returns

**avg** [array-like, shape (n_samples, n_classes)] Weighted average probability for each class per sample.

**score** (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

**X** [array-like of shape (n_samples, n_features)] Test samples.

**y** [array-like of shape (n_samples,), or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (self, **params)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params().

Parameters

**params** [keyword arguments] Specific parameters using e.g. set_params(parameter_name=new_value). In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to ‘drop’. 
**transform**

Return class labels or probabilities for X for each estimator.

**Parameters**

- **X** (array-like, sparse matrix), shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **probabilities_or_labels**
  
  If `voting='soft' and flatten_transform=True` returns array-like of shape (n_classifiers, n_samples * n_classes), being class probabilities calculated by each classifier.

  If `voting='soft' and flatten_transform=False` array-like of shape (n_classifiers, n_samples, n_classes)

  If `voting='hard'` array-like of shape (n_samples, n_classifiers), being class labels predicted by each classifier.

**Examples using sklearn.ensemble.VotingClassifier**

- Plot the decision boundaries of a VotingClassifier
- Plot class probabilities calculated by the VotingClassifier

### 7.11.10 sklearn.ensemble.VotingRegressor

class sklearn.ensemble.VotingRegressor (estimators, weights=None, n_jobs=None)

Prediction voting regressor for unfitted estimators.

New in version 0.21.

A voting regressor is an ensemble meta-estimator that fits base regressors each on the whole dataset. It then, averages the individual predictions to form a final prediction.

Read more in the User Guide.

**Parameters**

- **estimators** [list of (str, estimator) tuples] Invoking the fit method on the VotingRegressor will fit clones of those original estimators that will be stored in the class attribute self.estimators_. An estimator can be set to 'drop' using set_params.

  Deprecated since version 0.22: Using None to drop an estimator is deprecated in 0.22 and support will be dropped in 0.24. Use the string 'drop' instead.

- **weights** [array-like, shape (n_regressors,), optional (default='None')] Sequence of weights (float or int) to weight the occurrences of predicted values before averaging. Uses uniform weights if None.

- **n_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Attributes**
estimators_ [list of regressors] The collection of fitted sub-estimators as defined in
estimators that are not ‘drop’.

named_estimators_ [Bunch object, a dictionary with attribute access] Attribute to access any
fitted sub-estimators by name.

New in version 0.20.

See also:

**VotingClassifier** Soft Voting/Majority Rule classifier.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import VotingRegressor

>>> r1 = LinearRegression()
>>> r2 = RandomForestRegressor(n_estimators=10, random_state=1)
>>> X = np.array([[1, 1], [2, 4], [3, 9], [4, 16], [5, 25], [6, 36]])
>>> y = np.array([2, 6, 12, 20, 30, 42])
>>> er = VotingRegressor([('lr', r1), ('rf', r2)])
>>> print(er.fit(X, y).predict(X))
[ 3.3 5.7 11.8 19.7 28. 40.3]
```

**Methods**

<table>

__init__ (self, estimators, weights=None, n_jobs=None)
Initialize self. See help(type(self)) for accurate signature.

**fit** (self, X, y, sample_weight=None)
Fit the estimators.

**Parameters**

- **X** [array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where
  n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape (n_samples,)] Target values.
- **sample_weight** [array-like, shape (n_samples,),] or None] Sample weights. If None, then
  samples are equally weighted. Note that this is supported only if all underlying estimators
  support sample weights.
Returns

```
self  [object] Fitted estimator.
```

**fit_transform**(self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

```
X  [numpy array of shape [n_samples, n_features]] Training set.

y  [numpy array of shape [n_samples]] Target values.

**fit_params  [dict] Additional fit parameters.
```

Returns

```
X_new  [numpy array of shape [n_samples, n_features_new]] Transformed array.
```

**get_params**(self, deep=True)

Get the parameters of an estimator from the ensemble.

Parameters

```
deep  [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.
```

**predict**(self, X)

Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

```
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples.
```

Returns

```
y  [array of shape (n_samples,)] The predicted values.
```

**score**(self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

```
X  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.
```

Returns

```
score  [float] $R^2$ of self.predict(X) wrt. y.
```

7.11. *sklearn.ensemble*: Ensemble Methods
Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

`set_params` *(self, **params)*

Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`.

Parameters

**params [keyword arguments]** Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to 'drop'.

`transform` *(self, X)*

Return predictions for X for each estimator.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] The input samples.

Returns

predictions: array of shape (n_samples, n_classifiers) Values predicted by each regressor.

Examples using `sklearn.ensemble.VotingRegressor`

- Plot individual and voting regression predictions

7.11.11 `sklearn.ensemble.HistGradientBoostingRegressor`

class `sklearn.ensemble.HistGradientBoostingRegressor` *(loss='least_squares', learning_rate=0.1, max_iter=100, max_leaf_nodes=31, max_depth=None, min_samples_leaf=20, l2_regularization=0.0, max_bins=255, warm_start=False, scoring=None, validation_fraction=0.1, n_iter_no_change=None, tol=1e-07, verbose=0, random_state=None)*

Histogram-based Gradient Boosting Regression Tree.

This estimator is much faster than `GradientBoostingRegressor` for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain. When predicting, samples with missing values are assigned to the left or right child consequently. If no missing
values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

**Note:** This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_hist_gradient_boosting`:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

Read more in the *User Guide*.

New in version 0.21.

**Parameters**

- **loss** [{‘least_squares’, ‘least_absolute_deviation’}, optional (default='least_squares')] The loss function to use in the boosting process. Note that the “least squares” loss actually implements an “half least squares loss” to simplify the computation of the gradient.

- **learning_rate** [float, optional (default=0.1)] The learning rate, also known as shrinkage. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.

- **max_iter** [int, optional (default=100)] The maximum number of iterations of the boosting process, i.e. the maximum number of trees.

- **max_leaf_nodes** [int or None, optional (default=31)] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

- **max_depth** [int or None, optional (default=None)] The maximum depth of each tree. The depth of a tree is the number of nodes to go from the root to the deepest leaf. Must be strictly greater than 1. Depth isn’t constrained by default.

- **min_samples_leaf** [int, optional (default=20)] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

- **l2_regularization** [float, optional (default=0)] The L2 regularization parameter. Use 0 for no regularization (default).

- **max_bins** [int, optional (default=255)] The maximum number of bins to use for non-missing values. Before training, each feature of the input array $X$ is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than `max_bins` bins. In addition to the `max_bins` bins, one more bin is always reserved for missing values. Must be no larger than 255.

- **warm_start** [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See the Glossary.

- **scoring** [str or callable or None, optional (default=None)] Scoring parameter to use for early stopping. It can be a single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*). If None, the estimator’s default scorer is used. If `scoring='loss'`, early stopping is checked w.r.t the loss value. Only used if `n_iter_no_change` is not None.
validation_fraction [int or float or None, optional (default=0.1)] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if n_iter_no_change is not None.

n_iter_no_change [int or None, optional (default=None)] Used to determine when to “early stop”. The fitting process is stopped when none of the last n_iter_no_change scores are better than the n_iter_no_change - 1 -th-to-last one, up to some tolerance. If None or 0, no early-stopping is done.

tol [float or None, optional (default=1e-7)] The absolute tolerance to use when comparing scores during early stopping. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

verbose: int, optional (default=0) The verbosity level. If not zero, print some information about the fitting process.

random_state [int, np.random.RandomStateInstance or None, optional (default=None)] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. See random_state.

Attributes

n_iter_ [int] The number of iterations as selected by early stopping (if n_iter_no_change is not None). Otherwise it corresponds to max_iter.

n_trees_per_iteration_ [int] The number of tree that are built at each iteration. For regressors, this is always 1.

train_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. If scoring is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

validation_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. Empty if no early stopping or if validation_fraction is None.

Examples

```python
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> est = HistGradientBoostingRegressor().fit(X, y)
>>> est.score(X, y)
0.98...
```

Methods

```python
fit(self, X, y)  Fit the gradient boosting model.
get_params(self[, deep])  Get parameters for this estimator.
predict(self, X)  Predict values for X.
```
Table 81 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>score</code></td>
<td>Return the coefficient of determination $R^2$ of the prediction.</td>
</tr>
<tr>
<td><code>set_params</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

```python
__init__(self, loss='least_squares', learning_rate=0.1, max_iter=100, max_leaf_nodes=31,
         max_depth=None, min_samples_leaf=20, l2_regularization=0.0, max_bins=255,
         warm_start=False, scoring=None, validation_fraction=0.1, n_iter_no_change=None,
         tol=1e-07, verbose=0, random_state=None)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit(self, X, y)
```

Fit the gradient boosting model.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] The input samples.
- `y` [array-like of shape (n_samples,)] Target values.

**Returns**

- `self` [object]

```python
get_params(self, deep=True)
```

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names mapped to their values.

```python
predict(self, X)
```

Predict values for X.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- `y` [ndarray, shape (n_samples,)] The predicted values.

```python
score(self, X, y, sample_weight=None)
```

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - \text{y_true.mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- `y` [array-like of shape (n_samples,)] or (n_samples, n_outputs)] True values for X.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with $r^2$ score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call $r^2$ score directly or make a custom scorer with make_scorer (the built-in scorer 'r^2' uses multioutput='uniform_average').

```python
def set_params(self, **params):
    # Set the parameters of this estimator.

    # The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
    # parameters of the form <component>__<parameter> so that it’s possible to update each component
    # of a nested object.

    **params [dict] Estimator parameters.
    
    Returns
    self [object] Estimator instance.
```

Examples using sklearn.ensemble.HistGradientBoostingRegressor

- Combine predictors using stacking
- Partial Dependence Plots

7.11.12 sklearn.ensemble.HistGradientBoostingClassifier

class sklearn.ensemble.HistGradientBoostingClassifier (loss='auto',
    learning_rate=0.1, max_iter=100,
    max_leaf_nodes=31, max_depth=None,
    min_samples_leaf=20, l2_regularization=0.0,
    max_bins=255, warm_start=False,
    scoring=None, validation_fraction=0.1,
    n_iter_no_change=None, tol=1e-07, verbose=0, random_state=None)

Histogram-based Gradient Boosting Classification Tree.

This estimator is much faster than GradientBoostingClassifier for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain. When predicting, samples with missing values are assigned to the left or right child consequently. If no missing
values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_hist_gradient_boosting`:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

Read more in the User Guide.

New in version 0.21.

Parameters

- **loss** [str, `binary_crossentropy`, `categorical_crossentropy`], optional (default='auto')
  The loss function to use in the boosting process. `binary_crossentropy` (also known as logistic loss) is used for binary classification and generalizes to `categorical_crossentropy` for multiclass classification. ‘auto’ will automatically choose either loss depending on the nature of the problem.

- **learning_rate** [float, optional (default=0.1)]
  The learning rate, also known as shrinkage. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.

- **max_iter** [int, optional (default=100)]
  The maximum number of iterations of the boosting process, i.e. the maximum number of trees for binary classification. For multiclass classification, `n_classes` trees per iteration are built.

- **max_leaf_nodes** [int or None, optional (default=31)]
  The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

- **max_depth** [int or None, optional (default=None)]
  The maximum depth of each tree. The depth of a tree is the number of nodes to go from the root to the deepest leaf. Must be strictly greater than 1. Depth isn’t constrained by default.

- **min_samples_leaf** [int, optional (default=20)]
  The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

- **l2_regularization** [float, optional (default=0)]
  The L2 regularization parameter. Use 0 for no regularization.

- **max_bins** [int, optional (default=255)]
  The maximum number of bins to use for non-missing values. Before training, each feature of the input array X is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than `max_bins` bins. In addition to the `max_bins` bins, one more bin is always reserved for missing values. Must be no larger than 255.

- **warm_start** [bool, optional (default=False)]
  When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See the Glossary.

- **scoring** [str or callable or None, optional (default=None)]
  Scoring parameter to use for early stopping. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the
estimator’s default scorer is used. If `scoring='loss'`, early stopping is checked w.r.t the loss value. Only used if `n_iter_no_change` is not None.

- **validation_fraction** [int or float or None, optional (default=0.1)] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data.

- **n_iter_no_change** [int or None, optional (default=None)] Used to determine when to “early stop”. The fitting process is stopped when none of the last `n_iter_no_change` scores are better than the `(n_iter_no_change - 1)`-th-to-last one, up to some tolerance. If None or 0, no early-stopping is done.

- **tol** [float or None, optional (default=1e-7)] The absolute tolerance to use when comparing scores. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

- **verbose:** int, optional (default=0) The verbosity level. If not zero, print some information about the fitting process.

- **random_state** [int, np.random.RandomStateInstance or None, optional (default=None)] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. See `random_state`.

**Attributes**

- **n_iter_** [int] The number of estimators as selected by early stopping (if `n_iter_no_change` is not None). Otherwise it corresponds to `max_iter`.

- **n_trees_per_iteration_** [int] The number of tree that are built at each iteration. This is equal to 1 for binary classification, and to `n_classes` for multiclass classification.

- **train_score_** [ndarray, shape (n_iter_+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. If `scoring` is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

- **validation_score_** [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. Empty if no early stopping or if `validation_fraction` is None.

**Examples**

```python
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_iris
>>> X, y = load_iris(return_X_y=True)
>>> clf = HistGradientBoostingClassifier().fit(X, y)
>>> clf.score(X, y)
1.0
```

**Methods**
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

<td>Fit the gradient boosting model.</td>
</tr>
<tr>
<td><code>get_params(self[, deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>predict(self, X)</code></td>
<td>Predict classes for X.</td>
</tr>
<tr>
<td><code>predict_proba(self, X)</code></td>
<td>Predict class probabilities for X.</td>
</tr>
<tr>
<td><code>score(self, X, y[, sample_weight])</code></td>
<td>Return the mean accuracy on the given test data and labels.</td>
</tr>
<tr>
<td><code>set_params(self, **params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**__init__ (self, loss='auto', learning_rate=0.1, max_iter=100, max_leaf_nodes=31, max_depth=None, min_samples_leaf=20, l2_regularization=0.0, max_bins=255, warm_start=False, scoring=None, validation_fraction=0.1, n_iter_no_change=None, tol=1e-07, verbose=0, random_state=None)**

Initialize self. See help(type(self)) for accurate signature.

**decision_function (self, X)**

Compute the decision function of X.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- **decision** [ndarray, shape (n_samples,) or (n_samples, n_trees_per_iteration)] The raw predicted values (i.e. the sum of the trees leaves) for each sample. `n_trees_per_iteration` is equal to the number of classes in multiclass classification.

**fit (self, X, y)**

Fit the gradient boosting model.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The input samples.
- **y** [array-like of shape (n_samples,)] Target values.

**Returns**

- **self** [object]

**get_params (self, deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict (self, X)**

Predict classes for X.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- **y** [ndarray, shape (n_samples,)] The predicted classes.
predict_proba (self, X)
Predict class probabilities for X.

Parameters
X [array-like, shape (n_samples, n_features)] The input samples.

Returns
p [ndarray, shape (n_samples, n_classes)] The class probabilities of the input samples.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

Examples using sklearn.ensemble.HistGradientBoostingClassifier

• Release Highlights for scikit-learn 0.22

7.12 sklearn.exceptions: Exceptions and warnings

The sklearn.exceptions module includes all custom warnings and error classes used across scikit-learn.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exceptions.ChangedBehaviorWarning</td>
<td>Warning class used to notify the user of any change in the behavior.</td>
</tr>

<tr>
<td>exceptions.NonBLASDotWarning</td>
<td>Warning used when the dot operation does not use BLAS.</td>
</tr>
<tr>
<td>exceptions.UndefineMetricWarning</td>
<td>Warning used when the metric is invalid.</td>
</tr>
</tbody>
</table>

### 7.12.1 sklearn.exceptions.ChangedBehaviorWarning

#### class sklearn.exceptions.ChangedBehaviorWarning

Warning class used to notify the user of any change in the behavior.

Changed in version 0.18: Moved from sklearn.base.

**Attributes**

- args

**Methods**

- with_traceback() Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

### 7.12.2 sklearn.exceptions.ConvergenceWarning

#### class sklearn.exceptions.ConvergenceWarning

Custom warning to capture convergence problems.

**Attributes**

- args

**Examples**

```python
>>> import numpy as np
>>> import warnings
>>> from sklearn.cluster import KMeans
>>> from sklearn.exceptions import ConvergenceWarning
>>> warnings.simplefilter("always", ConvergenceWarning)
>>> X = np.array([[0, 0],
                [0, 1],
                [1, 0]],
               dtype = np.float)
```
with warnings.catch_warnings(record=True) as w:
    km = KMeans(n_clusters=4).fit(X)
    print(w[-1].message)
Number of distinct clusters (3) found smaller than n_clusters (4).
Possibly due to duplicate points in X.

Changed in version 0.18: Moved from sklearn.utils.

### Methods

#### with_traceback()

```python
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.
```

#### with_traceback()

```python
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.
```

### Examples using sklearn.exceptions.ConvergenceWarning

- Multiclass sparse logistic regression on 20newsgroups
- Early stopping of Stochastic Gradient Descent
- Compare Stochastic learning strategies for MLPClassifier
- Feature discretization

### 7.12.3 sklearn.exceptions.DataConversionWarning

```python
class sklearn.exceptions.DataConversionWarning
Warning used to notify implicit data conversions happening in the code.

This warning occurs when some input data needs to be converted or interpreted in a way that may not match the user’s expectations.
```

#### For example, this warning may occur when the user

- passes an integer array to a function which expects float input and will convert the input
- requests a non-copying operation, but a copy is required to meet the implementation’s data-type expectations;
- passes an input whose shape can be interpreted ambiguously.

Changed in version 0.18: Moved from sklearn.utils.validation.

#### Attributes

- args

#### Methods
with_traceback()  Exception.with_traceback(tb)  –  set self.__traceback__ to tb and return self.

with_traceback()  Exception.with_traceback(tb)  –  set self.__traceback__ to tb and return self.

7.12.4 sklearn.exceptions.DataDimensionalityWarning

class sklearn.exceptions.DataDimensionalityWarning
Custom warning to notify potential issues with data dimensionality.

For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

Changed in version 0.18: Moved from sklearn.utils.

Attributes

args

Methods

with_traceback()  Exception.with_traceback(tb)  –  set self.__traceback__ to tb and return self.

with_traceback()  Exception.with_traceback(tb)  –  set self.__traceback__ to tb and return self.

7.12.5 sklearn.exceptions.EfficiencyWarning

class sklearn.exceptions.EfficiencyWarning
Warning used to notify the user of inefficient computation.

This warning notifies the user that the efficiency may not be optimal due to some reason which may be included as a part of the warning message. This may be subclassed into a more specific Warning class.

New in version 0.18.

Attributes

args

Methods

with_traceback()  Exception.with_traceback(tb)  –  set self.__traceback__ to tb and return self.

with_traceback()  Exception.with_traceback(tb)  –  set self.__traceback__ to tb and return self.

7.12. sklearn.exceptions: Exceptions and warnings 1847
7.12.6 sklearn.exceptions.FitFailedWarning

class sklearn.exceptions.FitFailedWarning
    Warning class used if there is an error while fitting the estimator.

    This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation
    helper function cross_val_score to warn when there is an error while fitting the estimator.

    Attributes
    args

    Examples

    >>> from sklearn.model_selection import GridSearchCV
    >>> from sklearn.svm import LinearSVC
    >>> from sklearn.exceptions import FitFailedWarning
    >>> import warnings
    >>> warnings.simplefilter('always', FitFailedWarning)
    >>>
    >>> gs = GridSearchCV(LinearSVC(), {'C': [-1, -2]}, error_score=0, cv=2)
    >>> X, y = [[1, 2], [3, 4], [5, 6], [7, 8]], [0, 0, 1, 1]
    >>> with warnings.catch_warnings(record=True) as w:
    ...     try:
    ...         gs.fit(X, y)  # This will raise a ValueError since C is < 0
    ...     except ValueError:
    ...         pass
    ...     print(repr(w[-1].message))
    FitFailedWarning('Estimator fit failed. The score on this train-test
    partition for these parameters will be set to 0.000000.
    Details:...ValueError: Penalty term must be positive; got (C=-2)...

    Changed in version 0.18: Moved from sklearn.cross_validation.

    Methods

    Exception.with_traceback(tb) — set self.__traceback__ to tb and return self.

    with_traceback()

    Exception.with_traceback(tb) — set self.__traceback__ to tb and return self.

7.12.7 sklearn.exceptions.NotFittedError

class sklearn.exceptions.NotFittedError
    Exception class to raise if estimator is used before fitting.

    This class inherits from both ValueError and AttributeError to help with exception handling and backward
    compatibility.

    Attributes
    args

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...    LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...    print(repr(e))
NotFittedError("This LinearSVC instance is not fitted yet. Call 'fit' with appropriate arguments before using this estimator.")
```

Changed in version 0.18: Moved from sklearn.utils.validation.

Methods

```python
with_traceback() -- set self.__traceback__ to tb and return self.
```

```
with_traceback() -- set self.__traceback__ to tb and return self.
```

### 7.12.8 sklearn.exceptions.NonBLASDotWarning

class sklearn.exceptions.NonBLASDotWarning

Warning used when the dot operation does not use BLAS.

This warning is used to notify the user that BLAS was not used for dot operation and hence the efficiency may be affected.

Changed in version 0.18: Moved from sklearn.utils.validation, extends EfficiencyWarning.

Attributes

- `args`

Methods

```python
with_traceback() -- set self.__traceback__ to tb and return self.
```

```
with_traceback() -- set self.__traceback__ to tb and return self.
```

### 7.12.9 sklearn.exceptions.UndefinedMetricWarning

class sklearn.exceptions.UndefinedMetricWarning

Warning used when the metric is invalid

Changed in version 0.18: Moved from sklearn.base.

Attributes
7.13 sklearn.experimental: Experimental

The sklearn.experimental module provides importable modules that enable the use of experimental features or estimators.

The features and estimators that are experimental aren’t subject to deprecation cycles. Use them at your own risks!

---

### 7.13.1 sklearn.experimental.enable_hist_gradient_boosting

Enables histogram-based gradient boosting estimators.

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the sklearn.ensemble.HistGradientBoostingClassifier and sklearn.ensemble.HistGradientBoostingRegressor as attributes of the ensemble module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.ensemble import HistGradientBoostingRegressor
```

The `# noqa` comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.

---

### 7.13.2 sklearn.experimental.enable_iterative_imputer

Enables IterativeImputer

The API and results of this estimator might change without any deprecation cycle.

Importing this file dynamically sets sklearn.impute.IterativeImputer as an attribute of the impute module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer  # noqa
>>> # now you can import normally from impute
>>> from sklearn.impute import IterativeImputer
```
7.14 sklearn.feature_extraction: Feature Extraction

The `sklearn.feature_extraction` module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

**User guide:** See the Feature extraction section for further details.

---

**DictVectorizer**

```py
from sklearn.feature_extraction import DictVectorizer
```

**Transforms lists of feature-value mappings to vectors.**

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or scipy.sparse matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature “f” that can take on the values “ham” and “spam” will become two features in the output, one signifying “f=ham”, the other “f=spam”.

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as int, the DictVectorizer can be followed by `sklearn.preprocessing.OrdinalEncoder` to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the User Guide.

**Parameters**

- `dtype` [callable, optional] The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.
- `separator` [string, optional] Separator string used when constructing new features for one-hot coding.
- `sparse` [boolean, optional.] Whether transform should produce scipy.sparse matrices. True by default.
- `sort` [boolean, optional.] Whether `feature_names_` and `vocabulary_` should be sorted when fitting. True by default.

**Attributes**

- `feature_names_` [list] A list of length `n_features` containing the feature names (e.g., “f=ham” and “f=spam”).

See also:

- **FeatureHasher** performs vectorization using only a hash function.
- **sklearn.preprocessing.OrdinalEncoder** handles nominal/categorical features encoded as columns of arbitrary data types.

---

7.14. sklearn.feature_extraction: Feature Extraction 1851
Examples

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> X
array([[2., 0., 1.],
       [0., 1., 3.]])
>>> v.inverse_transform(X) == [{'bar': 2.0, 'foo': 1.0}, {'baz': 1.0, 'foo': 3.0}]
True
>>> v.transform({'foo': 4, 'unseen_feature': 3})
array([[0., 0., 4.]]))
```

Methods

- `fit(X[, y])`: Learn a list of feature name -> indices mappings.
- `fit_transform(X[, y])`: Learn a list of feature name -> indices mappings and transform X.
- `get_feature_names()`: Returns a list of feature names, ordered by their indices.
- `get_params([deep])`: Get parameters for this estimator.
- `inverse_transform(X[, dict_type])`: Transform array or sparse matrix X back to feature mappings.
- `restrict([support[, indices]])`: Restrict the features to those in support using feature selection.
- `set_params(**params)`: Set the parameters of this estimator.
- `transform(X)`: Transform feature->value dicts to array or sparse matrix.

```
__init__(self, dtype=<class 'numpy.float64'>, separator='=', sparse=True, sort=True)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X[, y=None])
Learn a list of feature name -> indices mappings.

Parameters

X [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

y [(ignored)]

Returns

self

fit_transform (self, X[, y=None])
Learn a list of feature name -> indices mappings and transform X.

Like fit(X) followed by transform(X), but does not require materializing X in memory.

Parameters

X [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).```
y [(ignored)]

Returns

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

get_feature_names (self)
Returns a list of feature names, ordered by their indices.
If one-of-K coding is applied to categorical features, this will include the constructed feature names but
not the original ones.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X, dict_type=<class 'dict'>)
Transform array or sparse matrix X back to feature mappings.
X must have been produced by this DictVectorizer’s transform or fit_transform method; it may only have
passed through transformers that preserve the number of features and their order.
In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than
the original ones.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample matrix.
dict_type [callable, optional] Constructor for feature mappings. Must conform to the col-
lections.Mapping API.

Returns

D [list of dict_type objects, length = n_samples] Feature mappings for the samples in X.

restrict (self, support, indices=False)
Restrict the features to those in support using feature selection.
This function modifies the estimator in-place.

Parameters

support [array-like] Boolean mask or list of indices (as returned by the get_support member
of feature selectors).
indices [boolean, optional] Whether support is a list of indices.

Returns

self

Examples

7.14. sklearn.feature_extraction: Feature Extraction 1853
from sklearn.feature_extraction import DictVectorizer
from sklearn.feature_selection import SelectKBest, chi2

v = DictVectorizer()

D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]

X = v.fit_transform(D)
support = SelectKBest(chi2, k=2).fit(X, [0, 1])

v.get_feature_names()
['bar', 'baz', 'foo']

v.restrict(support.get_support())

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or fit_transform will be silently ignored.

Parameters

X [Mapping or iterable over Mappings, length = n_samples] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

Returns

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

Examples using sklearn.feature_extraction.DictVectorizer

• Column Transformer with Heterogeneous Data Sources
• FeatureHasher and DictVectorizer Comparison

7.14.2 sklearn.feature_extraction.FeatureHasher

class sklearn.feature_extraction.FeatureHasher (n_features=1048576, input_type='dict',
dtype=<class 'numpy.float64'>, alternate_sign=True)

Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into scipy.sparse matrices, using a hash function to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version of Murmurhash3.
Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to DictVectorizer and CountVectorizer, intended for large-scale (online) learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the User Guide.

New in version 0.13.

Parameters

- **n_features** [integer, optional] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

- **input_type** [string, optional, default “dict”] Either “dict” (the default) to accept dictionaries over (feature_name, value); “pair” to accept pairs of (feature_name, value); or “string” to accept single strings. feature_name should be a string, while value should be a number. In the case of “string”, a value of 1 is implied. The feature_name is hashed to find the appropriate column for the feature. The value’s sign might be flipped in the output (but see non_negative, below).

- **dtype** [numpy type, optional, default np.float64] The type of feature values. Passed to scipy.sparse matrix constructors as the dtype argument. Do not set this to bool, np.boolean or any unsigned integer type.

- **alternate_sign** [boolean, optional, default True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

See also:

- DictVectorizer vectorizes string-valued features using a hash table.
- sklearn.preprocessing.OneHotEncoder handles nominal/categorical features.

Examples

```python
>>> from sklearn.feature_extraction import FeatureHasher

>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4},{'dog': 2, 'run': 5}]
>>> X = h.transform(D)
>>> X.toarray()
array([[ 0.,  0., -4., -1.,  0.,  0.,  0.,  0.,  0.,  2.],
      [ 0.,  0.,  0., -2., -5.,  0.,  0.,  0.,  0.,  0.]])
```

Methods

- **fit**(self[, X, y])  
  No-op.

- **fit_transform**(self, X[, y])  
  Fit to data, then transform it.

- **get_params**(self[, deep])  
  Get parameters for this estimator.

- **set_params**(self[, **params])  
  Set the parameters of this estimator.

- **transform**(self, raw_X)  
  Transform a sequence of instances to a scipy.sparse matrix.
__init__ (self, n_features=1048576, input_type='dict', dtype=<class 'numpy.float64'>, alter-
nate_sign=True)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X=None, y=None)
No-op.
This method doesn’t do anything. It exists purely for compatibility with the scikit-learn transformer API.

Parameters

X [array-like]

Returns

self [FeatureHasher]

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.
**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, raw_X)
Transform a sequence of instances to a scipy.sparse matrix.

Parameters
raw_X [iterable over iterable over raw features, length = n_samples] Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the input_type constructor argument) which will be hashed. raw_X need not support the len function, so it can be the result of a generator; n_samples is determined on the fly.

Returns

X [sparse matrix of shape (n_samples, n_features)] Feature matrix, for use with estimators or further transformers.

Examples using sklearn.feature_extraction.FeatureHasher

• FeatureHasher and DictVectorizer Comparison

7.14.3 From images

The sklearn.feature_extraction.image submodule gathers utilities to extract features from images.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_extraction.image.extract_patches_2d(...)</td>
<td>Reshape a 2D image into a collection of patches</td>
</tr>
<tr>
<td>feature_extraction.image.grid_to_graph(n_x, n_y)</td>
<td>Graph of the pixel-to-pixel connections</td>
</tr>
<tr>
<td>feature_extraction.image.img_to_graph(img[, ...])</td>

<td>Reconstruct the image from all of its patches.</td>
</tr>
<tr>
<td>sklearn.feature_extraction.image.PatchExtractor([...])</td>
<td>Extracts patches from a collection of images</td>
</tr>
</tbody>
</table>

sklearn.feature_extraction.image.extract_patches_2d

sklearn.feature_extraction.image.extract_patches_2d(image, patch_size, max_patches=None, random_state=None)

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the User Guide.

Parameters

image [array, shape = (image_height, image_width) or] (image_height, image_width, n_channels) The original image data. For color images, the last dimension specifies the channel: a RGB image would have n_channels=3.

patch_size [tuple of ints (patch_height, patch_width)] the dimensions of one patch

max_patches [integer or float, optional default is None] The maximum number of patches to extract. If max_patches is a float between 0 and 1, it is taken to be a proportion of the total number of patches.

random_state [int, RandomState instance or None, optional (default=None)] Determines the random number generator used for random sampling when max_patches is not None. Use an int to make the randomness deterministic. See Glossary.
Returns

patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the image, where n_patches is either max_patches or the total number of patches that can be extracted.

Examples

```python
>>> from sklearn.datasets import load_sample_image
>>> from sklearn.feature_extraction import image

# Use the array data from the first image in this dataset:
>>> one_image = load_sample_image("china.jpg")
>>> print('Image shape: ({}).format(one_image.shape))
Image shape: (427, 640, 3)
>>> patches = image.extract_patches_2d(one_image, (2, 2))
>>> print('Patches shape: ({}).format(patches.shape))
Patches shape: (272214, 2, 2, 3)
>>> # Here are just two of these patches:
>>> print(patches[1])
[[[174 201 231]
  [174 201 231]]
[[173 200 230]
  [173 200 230]])
```

Examples using sklearn.feature_extraction.image.extract_patches_2d

- Online learning of a dictionary of parts of faces
- Image denoising using dictionary learning

sklearn.feature_extraction.image.grid_to_graph

sklearn.feature_extraction.image.grid_to_graph(n_x, n_y, n_z=1, mask=None, return_as=<class 'scipy.sparse.coo.coo_matrix'>, dtype=<class 'int'>)

Graph of the pixel-to-pixel connections

Edges exist if 2 voxels are connected.

Parameters

- n_x [int] Dimension in x axis
- n_y [int] Dimension in y axis
- n_z [int, optional, default 1] Dimension in z axis
- mask [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.
**return_as** [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.

**dtype** [dtype, optional, default int] The data of the returned sparse matrix. By default it is int

**Notes**

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in np.asarray to avoid type issues.

```python
sklearn.feature_extraction.image.img_to_graph
```

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

**Parameters**

- **img** [ndarray, 2D or 3D] 2D or 3D image
- **mask** [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.
- **return_as** [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.
- **dtype** [None or dtype, optional] The data of the returned sparse matrix. By default it is the dtype of img

**Notes**

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in np.asarray to avoid type issues.

```python
sklearn.feature_extraction.image.reconstruct_from_patches_2d
```

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

**Parameters**
patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have n_channels=3.

image_size [tuple of ints (image_height, image_width) or] (image_height, image_width, n_channels) the size of the image that will be reconstructed

Returns

image [array, shape = image_size] the reconstructed image

Examples using sklearn.feature_extraction.image.reconstruct_from_patches_2d

• Image denoising using dictionary learning

sklearn.feature_extraction.image.PatchExtractor
class sklearn.feature_extraction.image.PatchExtractor(patch_size=None, max_patches=None, random_state=None)

Extracts patches from a collection of images
Read more in the User Guide.
New in version 0.9.

Parameters

patch_size [tuple of ints (patch_height, patch_width)] the dimensions of one patch

max_patches [integer or float, optional default is None] The maximum number of patches per image to extract. If max_patches is a float in (0, 1), it is taken to mean a proportion of the total number of patches.

random_state [int, RandomState instance or None, optional (default=None)] Determines the random number generator used for random sampling when max_patches is not None. Use an int to make the randomness deterministic. See Glossary.

Examples

```python
>>> from sklearn.datasets import load_sample_images
>>> from sklearn.feature_extraction import image

>>> # Use the array data from the second image in this dataset:
>>> X = load_sample_images().images[1]
>>> print('Image shape: {}
'.format(X.shape))
Image shape: (427, 640, 3)

>>> pe = image.PatchExtractor(patch_size=(2, 2))
>>> pe_fit = pe.fit(X)
>>> pe_trans = pe.transform(X)
>>> print('Patches shape: {}
'.format(pe_trans.shape))
Patches shape: (545706, 2, 2)
```

Methods
**fit**(self, X[, y])
Do nothing and return the estimator unchanged.

**get_params**(self[, deep])
Get parameters for this estimator.

**set_params**(self, **params)
Set the parameters of this estimator.

**transform**(self, X)
Transforms the image samples in X into a matrix of patch data.

**__init__**(self, patch_size=None, max_patches=None, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y=None)
Do nothing and return the estimator unchanged.
This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

-X [array-like, shape [n_samples, n_features]] Training data.

**get_params**(self, deep=True)
Get parameters for this estimator.

**Parameters**

-deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

-params [mapping of string to any] Parameter names mapped to their values.

**set_params**(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params [dict] Estimator parameters.

**Returns**

**transform**(self, X)
Transforms the image samples in X into a matrix of patch data.

**Parameters**

-X [array, shape = (n_samples, image_height, image_width) or] (n_samples, image_height, image_width, n_channels) Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have n_channels=3.

**Returns**

-patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the images, where n_patches is either n_samples * max_patches or the total number of patches that can be extracted.
7.14.4 From text

The `sklearn.feature_extraction.text` submodule gathers utilities to build feature vectors from text documents.

<table>
<thead>
<tr>
<th>Submodule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CountVectorizer</strong></td>
<td>Convert a collection of text documents to a matrix of token counts</td>
</tr>
<tr>
<td><strong>HashingVectorizer</strong></td>
<td>Convert a collection of text documents to a matrix of token occurrences</td>
</tr>
<tr>
<td><strong>TfidfTransformer</strong></td>
<td>Transform a count matrix to a normalized tf or tf-idf representation</td>
</tr>
<tr>
<td><strong>TfidfVectorizer</strong></td>
<td>Convert a collection of raw documents to a matrix of TF-IDF features</td>
</tr>
</tbody>
</table>

**`sklearn.feature_extraction.text.CountVectorizer`**

```python
class sklearn.feature_extraction.text.CountVectorizer(input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=<class 'numpy.int64'>)
```

Convert a collection of text documents to a matrix of token counts.

This implementation produces a sparse representation of the counts using `scipy.sparse.csr_matrix`.

If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data.

Read more in the User Guide.

**Parameters**

- **input** [string {'filename', 'file', 'content' }] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.
  
  If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.
  
  Otherwise the input is expected to be a sequence of items that can be of type string or byte.

- **encoding** [string, 'utf-8' by default.] If bytes or files are given to analyze, this encoding is used to decode.

- **decode_error** [ ['strict', 'ignore', 'replace']] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

---

1862 Chapter 7. API Reference
strip_accents [{'ascii', 'unicode', None}] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from `unicodedata.normalize`.

lowercase [boolean, True by default] Convert all characters to lowercase before tokenizing.

preprocessor [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if `analyzer` is not callable.

tokenizer [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer` == 'word'.

stop_words [string {'english'}, list, or None (default)] If 'english', a built-in stop word list for English is used. There are several known issues with 'english' and you should consider an alternative (see `Using stop words`).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer` == 'word'.

If None, no stop words will be used. `max_df` can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

token_pattern [string] Regular expression denoting what constitutes a “token”, only used if `analyzer` == 'word'. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

ngram_range [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different word n-grams or char n-grams to be extracted. All values of n such such that min_n <= n <= max_n will be used. For example an `ngram_range` of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if `analyzer` is not callable.

analyzer [string, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word n-gram or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable analyzer.

max_df [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

min_df [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

max_features [int or None, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.
This parameter is ignored if vocabulary is not None.

**vocabulary**  [Mapping or iterable, optional] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

**binary**  [boolean, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**dtype**  [type, optional] Type of the matrix returned by fit_transform() or transform().

**Attributes**

**vocabulary**  [dict] A mapping of terms to feature indices.

**fixed_vocabulary**  [boolean] True if a fixed vocabulary of term to indices mapping is provided by the user

**stop_words**  [set] Terms that were ignored because they either:
- occurred in too many documents (max_df)
- occurred in too few documents (min_df)
- were cut off by feature selection (max_features).

This is only available if no vocabulary was given.

**See also:**

HashingVectorizer, TfidfVectorizer

**Notes**

The **stop_words** attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

**Examples**

```python
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> corpus = [
...   'This is the first document.',
...   'This document is the second document.',
...   'And this is the third one.',
...   'Is this the first document?',
...]
>>> vectorizer = CountVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.toarray())
[[0 1 1 1 0 0 1 0 1]
 [0 2 0 1 0 1 0 1]
 [1 0 0 1 0 0 1 1]
 [0 1 1 0 0 1 0 1]]
>>> vectorizer2 = CountVectorizer(analyzer='word', ngram_range=(2, 2))
>>> X2 = vectorizer2.fit_transform(corpus)
>>> print(vectorizer2.get_feature_names())
```

(continues on next page)
['and this', 'document is', 'first document', 'is the', 'is this', 'second document', 'the first', 'the second', 'the third', 'third one', 'this document', 'this is', 'this the']

```python
>>> print(X2.toarray())
[[0 1 1 0 0 1 0 0 0 1 0]
 [0 1 0 1 0 1 0 0 1 0 0]
 [1 0 0 1 0 0 0 1 1 0 1]
 [0 0 1 0 1 0 1 0 0 0 0]]
```

### Methods

- `build_analyzer(self)`: Return a callable that handles preprocessing, tokenization and n-grams generation.
- `build_preprocessor(self)`: Return a function to preprocess the text before tokenization.
- `build_tokenizer(self)`: Return a function that splits a string into a sequence of tokens.
- `decode(self, doc)`: Decode the input into a string of unicode symbols.
- `fit(self, raw_documents[, y])`: Learn a vocabulary dictionary of all tokens in the raw documents.
- `fit_transform(self, raw_documents[, y])`: Learn the vocabulary dictionary and return term-document matrix.
- `get_feature_names(self)`: Array mapping from feature integer indices to feature name.
- `get_params(self[, deep])`: Get parameters for this estimator.
- `get_stop_words(self)`: Build or fetch the effective stop words list.
- `inverse_transform(self, X)`: Return terms per document with nonzero entries in X.
- `set_params(self, 
`params``)`: Set the parameters of this estimator.
- `transform(self, raw_documents)`: Transform documents to document-term matrix.

```python
__init__(self, input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=\n<class 'numpy.int64'>)
```

Initialize self. See help(type(self)) for accurate signature.

- `build_analyzer(self)`: Return a callable that handles preprocessing, tokenization and n-grams generation.
  
  **Returns**
  
  - **analyzer**: callable A function to handle preprocessing, tokenization and n-grams generation.

- `build_preprocessor(self)`: Return a function to preprocess the text before tokenization.
  
  **Returns**
  
  - **preprocessor**: callable A function to preprocess the text before tokenization.
Return a function that splits a string into a sequence of tokens.

Returns

tokenizer: callable A function to split a string into a sequence of tokens.

decode (self, doc)
Decode the input into a string of unicode symbols.

Parameters
doc [str] The string to decode.

Returns
doc: str A string of unicode symbols.

fit (self, raw_documents, y=None)
Learn a vocabulary dictionary of all tokens in the raw documents.

Parameters
raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns
self

fit_transform (self, raw_documents, y=None)
Learn the vocabulary dictionary and return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters
raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

get_feature_names (self)
Array mapping from feature integer indices to feature name.

Returns
feature_names [list] A list of feature names.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
depth [bool, default=1] True If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

get_stop_words (self)
Build or fetch the effective stop words list.

Returns
stop_words: list or None A list of stop words.
inverse_transform (self, X)
Return terms per document with nonzero entries in X.

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

Returns
X_inv [list of arrays, len = n_samples] List of arrays of terms.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

transform (self, raw_documents)
Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to the constructor.

Parameters
raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

Examples using sklearn.feature_extraction.text.CountVectorizer

• Sample pipeline for text feature extraction and evaluation
Convert a collection of text documents to a matrix of token occurrences

It turns a collection of text documents into a scipy.sparse matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if norm='l1' or projected on the euclidean unit sphere if norm='l2'.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

• it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
• it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
• it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a CountVectorizer with an in-memory vocabulary):

• there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
• there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if n_features is large enough (e.g. 2 ** 18 for text classification problems).
• no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the User Guide.

Parameters

input [string {‘filename’, ‘file’, ‘content’}] If ‘filename’, the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze. If ‘file’, the sequence items must have a ‘read’ method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

encoding [string, default=’utf-8’] If bytes or files are given to analyze, this encoding is used to decode.
**decode_error** [{'strict', 'ignore', 'replace'}] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is ‘strict’, meaning that a UnicodeDecodeError will be raised. Other values are ‘ignore’ and ‘replace’.

**strip_accents** [{'ascii', 'unicode', None}] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from `unicodedata.normalize`.

**lowercase** [boolean, default=True] Convert all characters to lowercase before tokenizing.

**preprocessor** [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if `analyzer` is not callable.

**tokenizer** [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer` == 'word'.

**stop_words** [string {'english'}, list, or None (default)] If ‘english’, a built-in stop word list for English is used. There are several known issues with ‘english’, a built-in stop word list for English is used. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer` == 'word'.

**token_pattern** [string] Regular expression denoting what constitutes a “token”, only used if `analyzer` == 'word'. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**ngram_range** [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if `analyzer` is not callable.

**analyzer** [string, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**n_features** [integer, default=(2 ** 20)] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

**binary** [boolean, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**norm** ['l1', 'l2' or None, optional] Norm used to normalize term vectors. None for no normalization.
**alternate_sign** [boolean, optional, default True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

New in version 0.19.

**dtype** [type, optional] Type of the matrix returned by fit_transform() or transform().

See also:

*CountVectorizer*, *TfidfVectorizer*

**Examples**

```python
>>> from sklearn.feature_extraction.text import HashingVectorizer
>>> corpus = ['This is the first document.',
... 'This document is the second document.',
... 'And this is the third one.',
... 'Is this the first document?']
>>> vectorizer = HashingVectorizer(n_features=2**4)
>>> X = vectorizer.fit_transform(corpus)
>>> print(X.shape)
(4, 16)
```

**Methods**

```python
build_analyzer(self) Return a callable that handles preprocessing, tokenization and n-grams generation.
build_preprocessor(self) Return a function to preprocess the text before tokenization.
build_tokenizer(self) Return a function that splits a string into a sequence of tokens.
decode(self, doc) Decode the input into a string of unicode symbols.
fit(self, X[, y]) Does nothing: this transformer is stateless.
fit_transform(self, X[, y]) Transform a sequence of documents to a document-term matrix.
get_params(self[, deep]) Get parameters for this estimator.
get_stop_words(self) Build or fetch the effective stop words list.
partial_fit(self, X[, y]) Does nothing: this transformer is stateless.
set_params(self, **params) Set the parameters of this estimator.
transform(self, X) Transform a sequence of documents to a document-term matrix.
```

__init__ (self, input=`content`, encoding=`utf-8`, decode_error=`strict`, strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern=`\b\w\w+\b`, ngram_range=(1, 1), analyzer=`word`, n_features=1048576, binary=False, norm=`l2`, alternate_sign=True, dtype=<class 'numpy.float64'>) Initialize self. See help(type(self)) for accurate signature.

build_analyzer (self) Return a callable that handles preprocessing, tokenization and n-grams generation.
Returns

**analyzer**: callable  A function to handle preprocessing, tokenization and n-grams generation.

**build_preprocessor**(self)

Return a function to preprocess the text before tokenization.

Returns

**preprocessor**: callable  A function to preprocess the text before tokenization.

**build_tokenizer**(self)

Return a function that splits a string into a sequence of tokens.

Returns

**tokenizer**: callable  A function to split a string into a sequence of tokens.

**decode**(self, doc)

Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

**doc** [str] The string to decode.

Returns

**doc**: str  A string of unicode symbols.

**fit**(self, X, y=None)

Does nothing: this transformer is stateless.

Parameters

**X** [array-like, shape [n_samples, n_features]] Training data.

**fit_transform**(self, X, y=None)

Transform a sequence of documents to a document-term matrix.

Parameters

**X** [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

**y** [any] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

**X** [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

**get_params**(self, deep=True)

Get parameters for this estimator.

Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get_stop_words**(self)

Build or fetch the effective stop words list.
Returns

stop_words: list or None  A list of stop words.

partial_fit (self, X, y=None)

Does nothing: this transformer is stateless.

This method is just there to mark the fact that this transformer can work in a streaming setup.

Parameters

X  [array-like, shape [n_samples, n_features]] Training data.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

transform (self, X)

Transform a sequence of documents to a document-term matrix.

Parameters

X  [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

Returns

X  [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

Examples using sklearn.feature_extraction.text.HashingVectorizer

- Out-of-core classification of text documents
- Clustering text documents using k-means
- Classification of text documents using sparse features

sklearn.feature_extraction.text.TfidfTransformer

class sklearn.feature_extraction.text.TfidfTransformer (norm='l2', use_idf=True, smooth_idf=True, sublinear_tf=False)

Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.

The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.
The formula that is used to compute the tf-idf for a term \( t \) of a document \( d \) in a document set is:

\[
\text{tf-idf}(t, d) = \text{tf}(t, d) \times \text{idf}(t),
\]

where \( \text{tf}(t, d) \) is the term frequency of \( t \) in \( d \), \( \text{idf}(t) \) is the inverse document frequency of \( t \), \( n \) is the total number of documents in the document set, and \( df(t) \) is the document frequency of \( t \). The effect of adding “1” to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored. (Note that the idf formula above differs from the standard textbook notation that defines the idf as:

\[
\text{idf}(t) = \log \left( \frac{n}{df(t)} \right) + 1.
\]

If \( \text{smooth_idf}=\text{True} \) (the default), the constant “1” is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions:

\[
\text{idf}(d, t) = \log \left( \frac{1 + n}{1 + df(d, t)} \right) + 1.
\]

Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

- Tf is “n” (natural) by default, “l” (logarithmic) when \( \text{sublinear_tf}=\text{True} \).
- Idf is “t” when \( \text{use_idf} \) is given, “n” (none) otherwise.
- Normalization is “c” (cosine) when \( \text{norm}='\text{l2}' \), “n” (none) when \( \text{norm}=\text{None} \).

Read more in the User Guide.

**Parameters**

- **norm** [‘l1’, ‘l2’ or None, optional (default=’l2’)] Each output row will have unit norm, either:
  * ‘l2’: Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * ‘l1’: Sum of absolute values of vector elements is 1. See `preprocessing.normalize`.

- **use_idf** [boolean (default=\text{True})] Enable inverse-document-frequency reweighting.

- **smooth_idf** [boolean (default=\text{True})] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

- **sublinear_tf** [boolean (default=\text{False})] Apply sublinear tf scaling, i.e., replace tf with \( 1 + \log(tf) \).

**Attributes**

- **idf_** [array, shape (n_features)] The inverse document frequency (IDF) vector; only defined if \( \text{use_idf} \) is True.

**References**

[R1b90ac3ca370-Yates2011], [R1b90ac3ca370-MRS2008]

**Examples**

```python
>>> from sklearn.feature_extraction.text import TfidfTransformer
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> from sklearn.pipeline import Pipeline
>>> import numpy as np

>>> corpus = ['this is the first document',
            'this document is the second document',
            'and this is the third one',
            'is this the first document']
>>> vocabulary = ['this', 'document', 'first', 'is', 'second', 'the',
                 'and', 'one']
>>> pipe = Pipeline([('count', CountVectorizer(vocabulary=vocabulary))],
                  {'norm': 'l2', 'use_idf': True, 'smooth_idf': True, 'sublinear_tf': False})
```

(continues on next page)
... ('tfid', TfidfTransformer()).fit(corpus)

>>> pipe['count'].transform(corpus).toarray()
array([[1, 1, 1, 1, 0, 1, 0, 0],
       [1, 2, 0, 1, 1, 1, 0, 0],
       [1, 0, 0, 1, 0, 1, 1, 1],
       [1, 1, 1, 1, 0, 1, 0, 0]])

>>> pipe['tfid'].idf_
array([1. , 1.22314355, 1.51082562, 1. , 1.91629073,
       1. , 1.91629073, 1.91629073])

>>> pipe.transform(corpus).shape
(4, 8)

Methods

fit(self, X[, y])
Learn the idf vector (global term weights)

fit_transform(self, X[, y])
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

get_params(self[, deep])
Get parameters for this estimator.

set_params(self, **params)
Set the parameters of this estimator.

transform(self, X[, copy])
Transform a count matrix to a tf or tf-idf representation

__init__(self, norm='l2', use_idf=True, smooth_idf=True, sublinear_tf=False)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Learn the idf vector (global term weights)

Parameters

X [sparse matrix, [n_samples, n_features]] a matrix of term/token counts

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(self, X, copy=True)
Transform a count matrix to a tf or tf-idf representation

Parameters

X [sparse matrix, [n_samples, n_features]] a matrix of term/token counts

copy [boolean, default True] Whether to copy X and operate on the copy or perform in-place
operations.

Returns

vectors [sparse matrix, [n_samples, n_features]]

Examples using sklearn.feature_extraction.text.TfidfTransformer

- Sample pipeline for text feature extraction and evaluation

sklearn.feature_extraction.text.TfidfVectorizer

class sklearn.feature_extraction.text.TfidfVectorizer(input='content',
encoding='utf-8', decode_error='strict',
strip_accents=None, lowercase=True, preprocessor=None,
tokenizer=None, analyzer='word',
stop_words=None, token_pattern='(?u)\b\w\w+\b',
ngram_range=(1, 1),
max_df=1.0, min_df=1,
max_features=None,
vocabulary=None, binary=False, dtype=<class 'numpy.float64'>,
norm='l2', use_idf=True,
smooth_idf=True, sublinear_tf=False)

Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to CountVectorizer followed by TfidfTransformer.

Read more in the User Guide.
Parameters

**input** [str {'filename', 'file', 'content'}] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

**encoding** [str, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

**decode_error** [{'strict', 'ignore', 'replace'} (default='strict')] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

**strip_accents** [{'ascii', 'unicode', None} (default=None)] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from unicodedata.normalize.

**lowercase** [bool (default=True)] Convert all characters to lowercase before tokenizing.

**preprocessor** [callable or None (default=None)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if analyzer is not callable.

**tokenizer** [callable or None (default=None)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

**analyzer** [str, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if input is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**stop_words** [str {'english'}, list, or None (default=None)] If a string, it is passed to _check_stop_list and the appropriate stop list is returned. ‘english’ is currently the only supported string value. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

**token_pattern** [str] Regular expression denoting what constitutes a “token”, only used if analyzer == 'word'. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).
**ngram_range** [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if analyzer is not callable.

**max_df** [float in range [0.0, 1.0] or int (default=1.0)] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min_df** [float in range [0.0, 1.0] or int (default=1)] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max_features** [int or None (default=None)] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, optional (default=None)] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

**binary** [bool (default=False)] If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set idf and normalization to False to get 0/1 outputs).

**dtype** [type, optional (default=float64)] Type of the matrix returned by fit_transform() or transform().

**norm** ['l1', 'l2' or None, optional (default='l2')] Each output row will have unit norm, either:

- ‘l2’: Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * ‘l1’: Sum of absolute values of vector elements is 1. See preprocessing.normalize.

**use_idf** [bool (default=True)] Enable inverse-document-frequency reweighting.

**smooth_idf** [bool (default=True)] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

**sublinear_tf** [bool (default=False)] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

**Attributes**

- **vocabulary_** [dict] A mapping of terms to feature indices.
- **fixed_vocabulary_** : bool True if a fixed vocabulary of term to indices mapping is provided by the user
- **idf_** [array, shape (n_features)] The inverse document frequency (IDF) vector; only defined if use_idf is True.
- **stop_words_** [set] Terms that were ignored because they either:
  - occurred in too many documents (max_df)
  - occurred in too few documents (min_df)
  - were cut off by feature selection (max_features).

This is only available if no vocabulary was given.
See also:

**CountVectorizer** Transforms text into a sparse matrix of n-gram counts.

**TfidfTransformer** Performs the TF-IDF transformation from a provided matrix of counts.

Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using `delattr` or set to `None` before pickling.

Examples

```python
>>> from sklearn.feature_extraction.text import TfidfVectorizer

>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]

>>> vectorizer = TfidfVectorizer()
>>> X = vectorizer.fit_transform(corpus)

>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']

>>> print(X.shape)
(4, 9)
```

Methods

- `build_analyzer(self)`: Return a callable that handles preprocessing, tokenization and n-grams generation.
- `build_preprocessor(self)`: Return a function to preprocess the text before tokenization.
- `build_tokenizer(self)`: Return a function that splits a string into a sequence of tokens.
- `decode(self, doc)`: Decode the input into a string of unicode symbols.
- `fit(self, raw_documents[, y])`: Learn vocabulary and idf from training set.
- `fit_transform(self, raw_documents[, y])`: Learn vocabulary and idf, return term-document matrix.
- `get_feature_names(self)`: Array mapping from feature integer indices to feature name.
- `get_params(self[, deep])`: Get parameters for this estimator.
- `get_stop_words(self)`: Build or fetch the effective stop words list.
- `inverse_transform(self, X)`: Return terms per document with nonzero entries in X.
- `set_params(self, **params)`: Set the parameters of this estimator.
- `transform(self, raw_documents[, copy])`: Transform documents to document-term matrix.
__init__(self, input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, analyzer='word', stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=<class 'numpy.float64'>, norm='l2', use_idf=True, smooth_idf=True, sublinear_tf=False)

Initialize self. See help(type(self)) for accurate signature.

build_analyzer(self)

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

   analyzer: callable A function to handle preprocessing, tokenization and n-grams generation.

build_preprocessor(self)

Return a function to preprocess the text before tokenization.

Returns

   preprocessor: callable A function to preprocess the text before tokenization.

build_tokenizer(self)

Return a function that splits a string into a sequence of tokens.

Returns

   tokenizer: callable A function to split a string into a sequence of tokens.

decode(self, doc)

Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

   doc [str] The string to decode.

Returns

   doc: str A string of unicode symbols.

fit (self, raw_documents, y=None)

Learn vocabulary and idf from training set.

Parameters

   raw_documents [iterable] An iterable which yields either str, unicode or file objects.

   y [None] This parameter is not needed to compute tfidf.

Returns

   self [object] Fitted vectorizer.

fit_transform(self, raw_documents, y=None)

Learn vocabulary and idf, return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters

   raw_documents [iterable] An iterable which yields either str, unicode or file objects.

   y [None] This parameter is ignored.

Returns
X [sparse matrix, [n_samples, n_features]] Tf-idf-weighted document-term matrix.

`get_feature_names(self)`
Array mapping from feature integer indices to feature name.

Returns

`feature_names` [list] A list of feature names.

`get_params(self, deep=True)`
Get parameters for this estimator.

Parameters

`deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

`params` [mapping of string to any] Parameter names mapped to their values.

`get_stop_words(self)`
Build or fetch the effective stop words list.

Returns

`stop_words: list or None` A list of stop words.

`inverse_transform(self, X)`
Return terms per document with nonzero entries in X.

Parameters

`X` [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

Returns

`X_inv` [list of arrays, len = n_samples] List of arrays of terms.

`set_params(self, **params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

`**params` [dict] Estimator parameters.

Returns

`self` [object] Estimator instance.

`transform(self, raw_documents, copy='deprecated')`
Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit_transform).

Parameters

`raw_documents` [iterable] An iterable which yields either str, unicode or file objects.

`copy` [bool, default True] Whether to copy X and operate on the copy or perform in-place operations.

Deprecated since version 0.22: The `copy` parameter is unused and was deprecated in version 0.22 and will be removed in 0.24. This parameter will be ignored.
Returns

X  [sparse matrix, [n_samples, n_features]] Tf-idf-weighted document-term matrix.

Examples using sklearn.feature_extraction.text.TfidfVectorizer

- Biclustering documents with the Spectral Co-clustering algorithm
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Column Transformer with Heterogeneous Data Sources
- Clustering text documents using k-means
- Classification of text documents using sparse features

7.15 sklearn.feature_selection: Feature Selection

The sklearn.feature_selection module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

User guide: See the Feature selection section for further details.

7.15.1 sklearn.feature_selection.GenericUnivariateSelect

class sklearn.feature_selection.GenericUnivariateSelect (score_func=<function f_classif>, mode='percentile', param=1e-05)

Univariate feature selector with configurable strategy.

Read more in the User Guide.

Parameters
**score_func** [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). For modes ‘percentile’ or ‘kbest’ it can return a single array scores.

**mode** [{'percentile', 'k_best', 'fpr', 'fdr', 'fwe'}] Feature selection mode.

**param** [float or int depending on the feature selection mode] Parameter of the corresponding mode.

**Attributes**

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if score_func returned scores only.

See also:

*f_classif* ANOVA F-value between label/feature for classification tasks.

*mutual_info_classif* Mutual information for a discrete target.

*chi2* Chi-squared stats of non-negative features for classification tasks.

*f_regression* F-value between label/feature for regression tasks.

*mutual_info_regression* Mutual information for a continuous target.

*SelectPercentile* Select features based on percentile of the highest scores.

*SelectKBest* Select features based on the k highest scores.

*SelectFpr* Select features based on a false positive rate test.

*SelectFdr* Select features based on an estimated false discovery rate.

*SelectFwe* Select features based on family-wise error rate.

**Examples**

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import GenericUnivariateSelect, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> transformer = GenericUnivariateSelect(chi2, 'k_best', param=20)
>>> X_new = transformer.fit_transform(X, y)
>>> X_new.shape
(569, 20)
```

**Methods**

*fit*(self, X, y) Run score function on (X, y) and get the appropriate features.

*fit_transform*(self, X[, y]) Fit to data, then transform it.

*get_params*(self[, deep]) Get parameters for this estimator.

*get_support*(self[, indices]) Get a mask, or integer index, of the features selected

*inverse_transform*(self, X) Reverse the transformation operation

*set_params*(self, **params) Set the parameters of this estimator.

<table>
<thead>
<tr>
<th><strong>transform</strong> (self, X)</th>
<th>Reduce X to the selected features.</th>
</tr>
</thead>
</table>

```python
__init__(self, score_func=<function f_classif at 0x7f50f24e4d40>, mode='percentile', param=1e-05)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y)
```

Run score function on (X, y) and get the appropriate features.

**Parameters**

- X [array-like of shape (n_samples, n_features)] The training input samples.
- y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- self [object]

```python
fit_transform (self, X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.
- **fit_params [dict] Additional fit parameters.

**Returns**

- X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [mapping of string to any] Parameter names mapped to their values.

```python
get_support (self, indices=False)
```

Get a mask, or integer index, of the features selected

**Parameters**

- indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

- support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.
inverse_transform (self, X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.2 sklearn.feature_selection.SelectPercentile

class sklearn.feature_selection.SelectPercentile (score_func=<function f_classif>, percentile=10)
Select features according to a percentile of the highest scores.

Read more in the User Guide.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below “See also”). The default function only works with classification tasks.

percentile [int, optional, default=10] Percent of features to keep.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if score_func returned only scores.

See also:

f_classif ANOVA F-value between label-feature for classification tasks.
**mutual_info_classif** Mutual information for a discrete target.

**chi2** Chi-squared stats of non-negative features for classification tasks.

**f_regression** F-value between label/feature for regression tasks.

**mutual_info_regression** Mutual information for a continuous target.

**SelectKBest** Select features based on the k highest scores.

**SelectFpr** Select features based on a false positive rate test.

**SelectFdr** Select features based on an estimated false discovery rate.

**SelectFwe** Select features based on family-wise error rate.

**GenericUnivariateSelect** Univariate feature selector with configurable mode.

**Notes**

Ties between features with equal scores will be broken in an unspecified way.

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectPercentile, chi2

X, y = load_digits(return_X_y=True)

X.shape
(1797, 64)

X_new = SelectPercentile(chi2, percentile=10).fit_transform(X, y)

X_new.shape
(1797, 7)
```

**Methods**

```python
__init__(self, score_func=<function f_classif at 0x7f50f24e4d40>, percentile=10)
Initialize self. See help(type(self)) for accurate signature.

fit(self, X, y)
Run score function on (X, y) and get the appropriate features.

fit_transform(self, X[, y])
Fit to data, then transform it.

get_params(self[, deep])
Get parameters for this estimator.

get_support(self[, indices])
Get a mask, or integer index, of the features selected

inverse_transform(self, X)
Reverse the transformation operation

set_params(self, **params)
Set the parameters of this estimator.

transform(self, X)
Reduce X to the selected features.
```
Returns

self [object]

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.
**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (self, indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (self, X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.
Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using sklearn.feature_selection.SelectPercentile

- Feature agglomeration vs. univariate selection
- SVM-Anova: SVM with univariate feature selection

7.15.3 sklearn.feature_selection.SelectKBest

class sklearn.feature_selection.SelectKBest (score_func=<function f_classif>, k=10)

Select features according to the k highest scores.

Read more in the User Guide.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below “See also”). The default function only works with classification tasks.

k [int or “all”, optional, default=10] Number of top features to select. The “all” option bypasses selection, for use in a parameter search.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if score_func returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectFpr Select features based on a false positive rate test.
SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes
Ties between features with equal scores will be broken in an unspecified way.

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectKBest(chi2, k=20).fit_transform(X, y)
>>> X_new.shape
(1797, 20)
```

__init__(self, score_func=<function f_classif at 0x7f50f24e4d40>, k=10)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

** fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (self, indices=False)

Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (self, X)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)

Reduce X to the selected features.
Parameters

\(X\) [array of shape \([n_{\text{samples}}, n_{\text{features}}]\)] The input samples.

Returns

\(X_r\) [array of shape \([n_{\text{samples}}, n_{\text{selected_features}}]\)] The input samples with only the selected features.

Examples using `sklearn.feature_selection.SelectKBest`

- Pipeline Anova SVM
- Univariate Feature Selection
- Concatenating multiple feature extraction methods
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Classification of text documents using sparse features

7.15.4 `sklearn.feature_selection.SelectFpr`

class `sklearn.feature_selection.SelectFpr` (score_func=<function f_classif>, alpha=0.05)

Filter: Select the pvalues below alpha based on a FPR test.

FPR test stands for False Positive Rate test. It controls the total amount of false detections.

Read more in the User Guide.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See also”). The default function only works with classification tasks.

alpha [float, optional] The highest p-value for features to be kept.

Attributes

scores_ [array-like of shape \((n_{\text{features}},)\)] Scores of features.

pvalues_ [array-like of shape \((n_{\text{features}},)\)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.
chi2 Chi-squared stats of non-negative features for classification tasks.
mutual_info_classif
f_regression F-value between label/feature for regression tasks.
mutual_info_regression Mutual information between features and the target.
SelectPercentile Select features based on percentile of the highest scores.
SelectKBest Select features based on the k highest scores.
SelectFdr Select features based on an estimated false discovery rate.
SelectFwe Select features based on family-wise error rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.
Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFpr, chi2

>>> X, y = load_breast_cancer(return_X_y=True)

>>> X.shape
(569, 30)

>>> X_new = SelectFpr(chi2, alpha=0.01).fit_transform(X, y)

>>> X_new.shape
(569, 16)
```

</tr>
</tbody>
</table>

```python
__init__(self, score_func=<function f_classif at 0x7f50f24e4d40>, alpha=0.05)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y)
```

Run score function on (X, y) and get the appropriate features.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] The training input samples.
- `y` [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- `self` [object]

```python
fit_transform (self, X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- `X` [numpy array of shape [n_samples, n_features]] Training set.
- `y` [numpy array of shape [n_samples]] Target values.

**Returns**

- `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (self, indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather
than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If
indices is False, this is a boolean array of shape [# input features], in which an ele-
ment is True iff its corresponding feature is selected for retention. If indices is True,
this is an integer array of shape [# output features] whose values are indices into the input
feature vector.

inverse_transform (self, X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted
where features would have been removed by transform.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the se-
lected features.
7.15.5 sklearn.feature_selection.SelectFdr

class sklearn.feature_selection.SelectFdr (score_func=<function f_classif>, alpha=0.05)

Filter: Select the p-values for an estimated false discovery rate

This uses the Benjamini-Hochberg procedure. alpha is an upper bound on the expected false discovery rate.

Read more in the User Guide.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See also”). The default function only works with classification tasks.

alpha [float, optional] The highest uncorrected p-value for features to keep.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a contnuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

```python
__init__ (self, score_func=<function f_classif at 0x7f50f24e4d40>, alpha=0.05)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y)
```

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

```python
fit_transform (self, X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- ****fit_params [dict] Additional fit parameters.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

```python
get_support (self, indices=False)
```

Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

**support** [array] An index that selects the retained features from a feature vector. If **indices** is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If **indices** is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(self, X)
Reverse the transformation operation

**Parameters**

X [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**set_params**(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform**(self, X)
Reduce X to the selected features.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 7.15.6 sklearn.feature_selection.SelectFromModel

**class** sklearn.feature_selection.SelectFromModel(**estimator**, **threshold**=None, **prefit**=False, **norm_order**=1, **max_features**=None)

Meta-transformer for selecting features based on importance weights.

New in version 0.17.

**Parameters**

**estimator** [object] The base estimator from which the transformer is built. This can be both a fitted (if **prefit** is set to True) or a non-fitted estimator. The estimator must have either a feature_importances_ or coef_ attribute after fitting.
threshold [string, float, optional default None] The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If “median” (resp. “mean”), then the threshold value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., “1.25*mean”) may also be used. If None and if the estimator has a parameter penalty set to 11, either explicitly or implicitly (e.g. Lasso), the threshold used is 1e-5. Otherwise, “mean” is used by default.

prefit [bool, default False] Whether a prefit model is expected to be passed into the constructor directly or not. If True, transform must be called directly and SelectFromModel cannot be used with cross_val_score, GridSearchCV and similar utilities that clone the estimator. Otherwise train the model using fit and then transform to do feature selection.

norm_order [non-zero int, inf, -inf, default 1] Order of the norm used to filter the vectors of coefficients below threshold in the case where the coef_ attribute of the estimator is of dimension 2.

max_features [int or None, optional] The maximum number of features selected scoring above threshold. To disable threshold and only select based on max_features, set threshold=-np.inf.

New in version 0.20.

Attributes

estimator_ [an estimator] The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the SelectFromModel, i.e when prefit is False.

threshold_ [float] The threshold value used for feature selection.

Notes

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

```python
>>> from sklearn.feature_selection import SelectFromModel
>>> from sklearn.linear_model import LogisticRegression
>>> X = [[ 0.87, -1.34, 0.31 ],
... [-2.79, -0.02, -0.85 ],
... [-1.34, -0.48, -2.55 ],
... [ 1.92, 1.48, 0.65 ]]
>>> y = [0, 1, 0, 1]
>>> selector = SelectFromModel(estimator=LogisticRegression()).fit(X, y)
>>> selector.estimator_.coef_
array([[-0.3252302 , 0.83462377, 0.49750423]])
>>> selector.threshold_
0.55245...
>>> selector.get_support()
array([False,  True, False])
>>> selector.transform(X)
array([[ 1.34],
[-0.02],
[-0.48],
[ 1.48]])
```

```python
__init__(self, estimator, threshold=None, prefit=False, norm_order=1, max_features=None)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y=None, **fit_params)
```

Fit the SelectFromModel meta-transformer.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] The training input samples.
- `y` [array-like, shape (n_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).
- **fit_params** [Other estimator specific parameters]

**Returns**

- `self` [object]

```python
fit_transform (self, X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- `X` [numpy array of shape [n_samples, n_features]] Training set.
- `y` [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

**Returns**

- `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names mapped to their values.

```python
get_support (self, indices=False)
```

Get a mask, or integer index, of the features selected

**Parameters**
indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (self, X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

partial_fit (self, X, y=None, **fit_params)
Fit the SelectFromModel meta-transformer only once.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like, shape (n_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).

**fit_params [Other estimator specific parameters]

Returns

self [object]

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.
Examples using `sklearn.feature_selection.SelectFromModel`

- Feature selection using SelectFromModel and LassoCV
- Classification of text documents using sparse features

### 7.15.7 `sklearn.feature_selection.SelectFwe`

class `sklearn.feature_selection.SelectFwe(score_func=<function f_classif>, alpha=0.05)`

Filter: Select the p-values corresponding to Family-wise error rate

Read more in the [User Guide](#).

**Parameters**

- `score_func` [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is `f_classif` (see below “See also”). The default function only works with classification tasks.

- `alpha` [float, optional] The highest uncorrected p-value for features to keep.

**Attributes**

- `scores_` [array-like of shape (n_features,)] Scores of features.

- `pvalues_` [array-like of shape (n_features,)] p-values of feature scores.

See also:

- `f_classif` ANOVA F-value between label/feature for classification tasks.
- `chi2` Chi-squared stats of non-negative features for classification tasks.
- `f_regression` F-value between label/feature for regression tasks.
- `SelectPercentile` Select features based on percentile of the highest scores.
- `SelectKBest` Select features based on the k highest scores.
- `SelectFpr` Select features based on a false positive rate test.
- `SelectFdr` Select features based on an estimated false discovery rate.
- `GenericUnivariateSelect` Univariate feature selector with configurable mode.

#### Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFwe, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFwe(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 15)
```

#### Methods
### fit(self, X, y)
Run score function on (X, y) and get the appropriate features.

### fit_transform(self, X[, y])
Fit to data, then transform it.

### get_params(self[, deep])
Get parameters for this estimator.

### get_support(self[, indices])
Get a mask, or integer index, of the features selected.

### inverse_transform(self, X)
Reverse the transformation operation.

### set_params(self[, **params])
Set the parameters of this estimator.

### transform(self, X)
Reduce X to the selected features.

### __init__ (self, score_func=<function f_classif at 0x7f50f24e4d40>, alpha=0.05)
Initialize self. See help(type(self)) for accurate signature.

### fit (self, X, y)
Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

### fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- ****fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

### get_params (self, deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

### get_support (self, indices=False)
Get a mask, or integer index, of the features selected.

**Parameters**

- **indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

---

1900 Chapter 7. API Reference
support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** *(self, X)*
Reverse the transformation operation

**Parameters**

* X [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

* X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by `transform`.

**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

* **params** [dict] Estimator parameters.

**Returns**

* self [object] Estimator instance.

**transform** *(self, X)*
Reduce X to the selected features.

**Parameters**

* X [array of shape [n_samples, n_features]] The input samples.

**Returns**

* X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 7.15.8 sklearn.feature_selection.RFE

**class sklearn.feature_selection.RFE**(estimator, n_features_to_select=None, step=1, verbose=0)

Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and the importance of each feature is obtained either through a `coef_` attribute or through a `feature_importances_` attribute. Then, the least important features are pruned from current set of features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the *User Guide*.

**Parameters**
estimator [object] A supervised learning estimator with a fit method that provides information about feature importance either through a coef_ attribute or through a feature_importances_ attribute.

n_features_to_select [int or None (default=None)] The number of features to select. If None, half of the features are selected.

step [int or float, optional (default=1)] If greater than or equal to 1, then step corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then step corresponds to the percentage (rounded down) of features to remove at each iteration.

verbose [int, (default=0)] Controls verbosity of output.

Attributes
n_features_ [int] The number of selected features.
support_ [array of shape [n_features]] The mask of selected features.
ranking_ [array of shape [n_features]] The feature ranking, such that ranking_[i] corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.
estimator_ [object] The external estimator fit on the reduced dataset.

See also:
RFECV Recursive feature elimination with built-in cross-validated selection of the best number of features

Notes
Allows NaN/Inf in the input if the underlying estimator does as well.

[Re310f679c81e-1]

Examples
The following example shows how to retrieve the 5 most informative features in the Friedman #1 dataset.

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR

>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, 5, step=1)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True, True, True, True, False, False, False, False, False, False])
>>> selector.ranking_
array([1, 1, 1, 1, 6, 4, 3, 2, 5])
```

Methods
**decision_function** (self, X) Compute the decision function of X.

**fit** (self, X, y) Fit the RFE model and then the underlying estimator on the selected features.

**fit_transform** (self, X[, y]) Fit to data, then transform it.

**get_params** (self, deep) Get parameters for this estimator.

**get_support** (self[, indices]) Get a mask, or integer index, of the features selected.

**inverse_transform** (self, X) Reverse the transformation operation.

**predict** (self, X) Reduce X to the selected features and then predict using the

**predict_log_proba** (self, X) Predict class log-probabilities for X.

**predict_proba** (self, X) Predict class probabilities for X.

**score** (self, X, y) Reduce X to the selected features and then return the score of the

**set_params** (self, **params) Set the parameters of this estimator.

**transform** (self, X) Reduce X to the selected features.

---

__init__ (self, estimator, n_features_to_select=None, step=1, verbose=0) Initialize self. See help(type(self)) for accurate signature.

**decision_function** (self, X) Compute the decision function of X.

Parameters

X [[array-like or sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

score [array, shape = [n_samples, n_classes] or [n_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape [n_samples].

**fit** (self, X, y) Fit the RFE model and then the underlying estimator on the selected features.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.
y [array-like of shape (n_samples,)] The target values.

**fit_transform** (self, X, y=None, **fit_params) Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpay array of shape [n_samples, n_features]] Training set.
y [numpay array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

Returns

X_new [numpay array of shape [n_samples, n_features_new]] Transformed array.
**get_params** (*self, deep=True*)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**get_support** (*self, indices=False*)
Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

- **support** [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** (*self, X*)
Reverse the transformation operation

**Parameters**

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by `transform`.

**predict** (*self, X*)
Reduce X to the selected features and then predict using the underlying estimator.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **y** [array of shape [n_samples]] The predicted target values.

**predict_log_proba** (*self, X*)
Predict class log-probabilities for X.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **p** [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples.

The order of the classes corresponds to that in the attribute `classes_`.

**predict_proba** (*self, X*)
Predict class probabilities for X.
Parameters

X  [[array-like or sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

p  [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (self, X, y)

Reduce X to the selected features and then return the score of the underlying estimator.

Parameters

X  [array of shape [n_samples, n_features]] The input samples.
y  [array of shape [n_samples]] The target values.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

transform (self, X)

Reduce X to the selected features.

Parameters

X  [array of shape [n_samples, n_features]] The input samples.

Returns

X_r  [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using sklearn.feature_selection.RFE

- Recursive feature elimination

7.15.9 sklearn.feature_selection.RFECV

class sklearn.feature_selection.RFECV (estimator, step=1, min_features_to_select=1, cv=None, scoring=None, verbose=0, n_jobs=None)

Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters
**estimator** [object] A supervised learning estimator with a *fit* method that provides information about feature importance either through a *coef_* attribute or through a *feature_importances_* attribute.

**step** [int or float, optional (default=1)] If greater than or equal to 1, then *step* corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then *step* corresponds to the percentage (rounded down) of features to remove at each iteration. Note that the last iteration may remove fewer than *step* features in order to reach *min_features_to_select*.

**min_features_to_select** [int, (default=1)] The minimum number of features to be selected. This number of features will always be scored, even if the difference between the original feature count and *min_features_to_select* isn’t divisible by *step*.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for *cv* are:
- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if *y* is binary or multiclass, `sklearn.model_selection.StratifiedKFold` is used. If the estimator is a classifier or if *y* is neither binary nor multiclass, `sklearn.model_selection.KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: *cv* default value of None changed from 3-fold to 5-fold.

**scoring** [string, callable or None, optional, (default=None)] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

**verbose** [int, (default=0)] Controls verbosity of output.

**n_jobs** [int or None, optional (default=None)] Number of cores to run in parallel while fitting across folds. *None* means 1 unless in a *joblib.parallel_backend* context. *-1* means using all processors. See *Glossary* for more details.

**Attributes**

- **n_features_** [int] The number of selected features with cross-validation.
- **support_** [array of shape [n_features]] The mask of selected features.
- **ranking_** [array of shape [n_features]] The feature ranking, such that ranking_[i] corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.
- **grid_scores_** [array of shape [n_subsets_of_features]] The cross-validation scores such that grid_scores_[i] corresponds to the CV score of the i-th subset of features.
- **estimator_** [object] The external estimator fit on the reduced dataset.

See also:

**RFE** Recursive feature elimination
Notes

The size of grid_scores_ is equal to \( \text{ceil} \left( \frac{n\_features - \min\_features\_to\_select}{\text{step}} \right) + 1 \), where step is the number of features removed at each iteration.

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFECV
>>> from sklearn.svm import SVR

>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFECV(estimator, step=1, cv=5)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True, True, True, True, True, False, False, False, False, False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

```
__init__ (self, estimator, step=1, min_features_to_select=1, cv=None, scoring=None, verbose=0, n_jobs=None)
```
Initialize self. See help(type(self)) for accurate signature.

```python
decision_function (self, X)
```
Compute the decision function of $X$.

**Parameters**

- $X$ ([array-like or sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- $score$ [array, shape = [n_samples, n_classes] or [n_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape [n_samples].

**fit**(self, $X$, $y$, $groups$=None)

Fit the RFE model and automatically tune the number of selected features.

**Parameters**

- $X$ ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples is the number of samples and n_features is the total number of features.
- $y$ [array-like of shape (n_samples,)] Target values (integers for classification, real numbers for regression).
- $groups$ [array-like of shape (n_samples,) or None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_transform**(self, $X$, $y$=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- $X$ [numpy array of shape [n_samples, n_features]] Training set.
- $y$ [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

**Returns**

- $X_{new}$ [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params**(self, $deep$=True)

Get parameters for this estimator.

**Parameters**

- $deep$ [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- $params$ [mapping of string to any] Parameter names mapped to their values.

**get_support**(self, $indices$=False)

Get a mask, or integer index, of the features selected

**Parameters**

- $indices$ [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

**support** [array] An index that selects the retained features from a feature vector. If **indices** is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If **indices** is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(self, X)
Reverse the transformation operation

**Parameters**

X [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by **transform**.

**predict**(self, X)
Reduce X to the selected features and then predict using the underlying estimator.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

y [array of shape [n_samples]] The predicted target values.

**predict_log_proba**(self, X)
Predict class log-probabilities for X.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

p [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute **classes**_.

**predict_proba**(self, X)
Predict class probabilities for X.

**Parameters**

X [[array-like or sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute **classes**_.

**score**(self, X, y)
Reduce X to the selected features and then return the score of the underlying estimator.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.
y [array of shape [n_samples]] The target values.

**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**params [dict] Estimator parameters.**

**Returns**

self [object] Estimator instance.

**transform** *(self, X)*
Reduce X to the selected features.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.RFECV`

- Recursive feature elimination with cross-validation

### 7.15.10 `sklearn.feature_selection.VarianceThreshold`

```
class sklearn.feature_selection.VarianceThreshold(threshold=0.0)
```

Feature selector that removes all low-variance features.

This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used for unsupervised learning.

Read more in the User Guide.

**Parameters**

**threshold [float, optional] Features with a training-set variance lower than this threshold will be removed.**

The default is to keep all features with non-zero variance, i.e. remove the features that have the same value in all samples.

**Attributes**

variances_ [array, shape (n_features,)] Variances of individual features.

**Notes**

Allows NaN in the input.
Examples

The following dataset has integer features, two of which are the same in every sample. These are removed with the default setting for threshold:

```python
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

Methods

```python
fit(self, X[, y]) Learn empirical variances from X.
fit_transform(self, X[, y]) Fit to data, then transform it.
get_params(self[, deep]) Get parameters for this estimator.
get_support(self[, indices]) Get a mask, or integer index, of the features selected
inverse_transform(self, X) Reverse the transformation operation
set_params(self, **params) Set the parameters of this estimator.
transform(self, X) Reduce X to the selected features.

__init__(self, threshold=0.0) Initialize self. See help(type(self)) for accurate signature.
```

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features]) Sample vectors from which to compute variances.
- **y** (any) Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

**Returns**

- **self**

**fit_transform** (self, X=None, **fit_params)

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** ([numpy array of shape [n_samples, n_features]]) Training set.
- **y** ([numpy array of shape [n_samples]]) Target values.
- ****fit_params** ([dict]) Additional fit parameters.

**Returns**

- **X_new** ([numpy array of shape [n_samples, n_features_new]]) Transformed array.

**get_params** (self, deep=True)

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (self, indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (self, X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

feature_selection.chi2(X, y) Compute chi-squared stats between each non-negative feature and class.

7.15.11 sklearn.feature_selection.chi2

`sklearn.feature_selection.chi2(X, y)`

Compute chi-squared stats between each non-negative feature and class.

This score can be used to select the n_features features with the highest values for the test chi-squared statistic from X, which must contain only non-negative features such as booleans or frequencies (e.g., term counts in document classification), relative to the classes.

Recall that the chi-square test measures dependence between stochastic variables, so using this function “weeds out” the features that are the most likely to be independent of class and therefore irrelevant for classification.

Read more in the User Guide.

**Parameters**

- `X` [array-like, sparse matrix] of shape (n_samples, n_features)] Sample vectors.
- `y` [array-like of shape (n_samples,)] Target vector (class labels).

**Returns**

- `chi2` [array, shape = (n_features,)] chi2 statistics of each feature.
- `pval` [array, shape = (n_features,)] p-values of each feature.

**See also:**

- `f_classif` ANOVA F-value between label/feature for classification tasks.
- `f_regression` F-value between label/feature for regression tasks.

**Notes**

Complexity of this algorithm is O(n_classes * n_features).

**Examples using sklearn.feature_selection.chi2**

- Selecting dimensionality reduction with Pipeline and GridSearchCV
- SVM-Anova: SVM with univariate feature selection
- Classification of text documents using sparse features
7.15.12 sklearn.feature_selection.f_classif

```python
sklearn.feature_selection.f_classif(X, y)
```
Compute the ANOVA F-value for the provided sample.

Read more in the User Guide.

Parameters

- `X` [array-like, sparse matrix] shape = [n_samples, n_features] The set of regressors that will be tested sequentially.
- `y` [array of shape(n_samples)] The data matrix.

Returns

- `F` [array, shape = [n_features,]] The set of F values.
- `pval` [array, shape = [n_features,]] The set of p-values.

See also:

- `chi2` Chi-squared stats of non-negative features for classification tasks.
- `f_regression` F-value between label/feature for regression tasks.

Examples using sklearn.feature_selection.f_classif

- Univariate Feature Selection

7.15.13 sklearn.feature_selection.f_regression

```python
sklearn.feature_selection.f_regression(X, y, center=True)
```
Univariate linear regression tests.

Linear model for testing the individual effect of each of many regressors. This is a scoring function to be used in a feature selection procedure, not a free standing feature selection procedure.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is, `((X[:, i] - mean(X[:, i])) * (y - mean_y)) / (std(X[:, i]) * std(y))`.
2. It is converted to an F score then to a p-value.

For more on usage see the User Guide.

Parameters

- `X` [array-like, sparse matrix] shape = (n_samples, n_features) The set of regressors that will be tested sequentially.
- `y` [array of shape(n_samples,)] The data matrix
- `center` [True, bool,] If true, X and y will be centered.

Returns

- `F` [array, shape=(n_features,)] F values of features.
- `pval` [array, shape=(n_features,)] p-values of F-scores.

See also:
**mutual_info_regression** Mutual information for a continuous target.

**f_classif** ANOVA F-value between label/feature for classification tasks.

**chi2** Chi-squared stats of non-negative features for classification tasks.

**SelectKBest** Select features based on the k highest scores.

**SelectFpr** Select features based on a false positive rate test.

**SelectFdr** Select features based on an estimated false discovery rate.

**SelectFwe** Select features based on family-wise error rate.

**SelectPercentile** Select features based on percentile of the highest scores.

### Examples using `sklearn.feature_selection.f_regression`

- Feature agglomeration vs. univariate selection
- Comparison of F-test and mutual information
- Pipeline Anova SVM

### 7.15.14 sklearn.feature_selection.mutual_info_classif

sklearn.feature_selection.mutual_info_classif(X, y, discrete_features='auto', n_neighbors=3, copy=True, random_state=None)

Estimate mutual information for a discrete target variable.

Mutual information (MI) \cite{1} between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in \cite{2} and \cite{3}. Both methods are based on the idea originally proposed in \cite{4}.

It can be used for univariate features selection, read more in the [User Guide](#).

**Parameters**

- **X** [array_like or sparse matrix, shape (n_samples, n_features)] Feature matrix.
- **y** [array_like, shape (n_samples,)] Target vector.
- **discrete_features** [‘auto’, bool, array_like], default ‘auto’] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense X and to True for sparse X.
- **n_neighbors** [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see \cite{2} and \cite{3}. Higher values reduce variance of the estimation, but could introduce a bias.
- **copy** [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.
- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number generator.
generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

mi [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

Notes

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

7.15.15 sklearn.feature_selection.mutual_info_regression

sklearn.feature_selection.mutual_info_regression(X, y, discrete_features='auto', n_neighbors=3, copy=True, random_state=None)

Estimate mutual information for a continuous target variable.

Mutual information (MI) [1] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the User Guide.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Feature matrix.

y [array_like, shape (n_samples,)] Target vector.

discrete_features [‘auto’, bool, array_like], default ‘auto’) If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense X and to True for sparse X.

n_neighbors [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.

copy [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number generator.
generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

mi [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

Notes

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

7.16 sklearn.gaussian_process: Gaussian Processes

The sklearn.gaussian_process module implements Gaussian Process based regression and classification.

User guide: See the Gaussian Processes section for further details.

| sklearn.gaussian_process. GaussianProcessClassifier(...)| Gaussian process classification (GPC) based on Laplace approximation. |
| sklearn.gaussian_process. GaussianProcessRegressor(...)| Gaussian process regression (GPR). |

7.16.1 sklearn.gaussian_process.GaussianProcessClassifier

class sklearn.gaussian_process.GaussianProcessClassifier (kernel=None, optimizer='fmin_l_bfgs_b', n_restarts_optimizer=0, max_iter_predict=100, warm_start=False, copy_X_train=True, random_state=None, multi_class='one_vs_rest', n_jobs=None)

Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.
Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.
Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus-rest classifiers are fitted. Note that this class thus does not implement a true multi-class Laplace approximation.

Parameters

- **kernel** [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 * RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.
- **optimizer** [string or callable, optional (default: “fmin_l_bfgs_b”)] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```python
def optimizer(obj_func, initial_theta, bounds):
    # 'obj_func' is the objective function to be maximized, which
    # takes the hyperparameters theta as parameter and an
    # optional flag eval_gradient, which determines if the
    # gradient is returned additionally to the function value
    # 'initial_theta': the initial value for theta, which can be
    # used by local optimizers
    # 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the ‘L-BFGS-B’ algorithm from scipy.optimize.minimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

- `'fmin_l_bfgs_b'`

- **n_restarts_optimizer** [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer=0 implies that one run is performed.

- **max_iter_predict** [int, optional (default: 100)] The maximum number of iterations in Newton’s method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

- **warm_start** [bool, optional (default: False)] If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of _posterior_mode(). This can speed up convergence when _posterior_mode() is called several times on similar problems as in hyperparameter optimization. See the Glossary.

- **copy_X_train** [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

- **random_state** [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, random_state is the seed used by the random number
generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**multi_class** [string, default] Specifies how multi-class classification problems are handled. Supported are “one_vs_rest” and “one_vs_one”. In “one_vs_rest”, one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In “one_vs_one”, one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that “one_vs_one” does not support predicting probability estimates.

**n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Attributes**

**kernel_** [kernel object] The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

**log_marginal_likelihood_value_** [float] The log-marginal-likelihood of self.kernel_.theta

**classes_** [array-like of shape (n_classes,)] Unique class labels.

**n_classes_** [int] The number of classes in the training data

**Examples**

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import RBF

>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * RBF(1.0)
>>> gpc = GaussianProcessClassifier(kernel=kernel, ... random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2,:])
array([[0.83548752, 0.03228706, 0.13222543],
       [0.79064206, 0.06525643, 0.14410151]])
```

New in version 0.18.

**Methods**

- **fit**(self, X, y) Fit Gaussian process classification model
- **get_params**(self[, deep]) Get parameters for this estimator.
- **log_marginal_likelihood**(self[, theta, ...]) Returns log-marginal likelihood of theta for training data.
- **predict**(self, X) Perform classification on an array of test vectors X.
- **predict_proba**(self, X) Return probability estimates for the test vector X.

</tbody>
</table>

__init__(self, kernel=None, optimizer='fmin_l_bfgs_b', n_restarts_optimizer=0, max_iter_predict=100, warm_start=False, copy_X_train=True, random_state=None, multi_class='one_vs_rest', n_jobs=None)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Fit Gaussian process classification model

Parameters

- **X** [sequence of length n_samples] Feature vectors or other representations of training data. Could either be array-like with shape = (n_samples, n_features) or a list of objects.
- **y** [array-like of shape (n_samples,)] Target values, must be binary

Returns

- self [returns an instance of self.]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

log_marginal_likelihood (self, theta=None, eval_gradient=False, clone_kernel=True)
Returns log-marginal likelihood of theta for training data.
In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers are returned.

Parameters

- **theta** [array-like of shape (n_kernel_params,) or None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification, theta may be the hyperparameters of the compound kernel or of an individual kernel. In the latter case, all individual kernel get assigned the same theta values. If None, the precomputed log_marginal_likelihood of self.kernel_.theta is returned.
- **eval_gradient** [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that gradient computation is not supported for non-binary classification. If True, theta must not be None.
- **clone_kernel** [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

Returns

- **log_likelihood** [float] Log-marginal likelihood of theta for training data.
**log_likelihood_gradient** [array, shape = (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

**predict** *(self, X)*

Perform classification on an array of test vectors X.

**Parameters**

- **X** [sequence of length n_samples] Query points where the GP is evaluated for classification. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

**Returns**

- **C** [ndarray of shape (n_samples,)] Predicted target values for X, values are from classes_

**predict_proba** *(self, X)*

Return probability estimates for the test vector X.

**Parameters**

- **X** [sequence of length n_samples] Query points where the GP is evaluated for classification. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

**Returns**

- **C** [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**score** *(self, X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

### 7.16.2 `sklearn.gaussian_process.GaussianProcessRegressor`

```python
class sklearn.gaussian_process.GaussianProcessRegressor(kernel=None,
                                                                 alpha=1e-10,  # float or array-like, optional (default: 1e-10)
                                                                 optimizer='fmin_l_bfgs_b',  # string or callable, optional (default: "fmin_l_bfgs_b")
                                                                 n_restarts_optimizer=0,
                                                                 normalize_y=False,
                                                                 copy_X_train=True,
                                                                 random_state=None)
```

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, `GaussianProcessRegressor`:

- allows prediction without prior fitting (based on the GP prior)
- provides an additional method `sample_y(X)`, which evaluates samples drawn from the GPR (prior or posterior) at given inputs
- exposes a method `log_marginal_likelihood(theta)`, which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the User Guide.

New in version 0.18.

#### Parameters

- **kernel** [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 * RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

- **alpha** [float or array-like, optional (default: 1e-10)] Value added to the diagonal of the kernel matrix during fitting. Larger values correspond to increased noise level in the observations. This can also prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite matrix. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Note that this is equivalent to adding a WhiteKernel with c=alpha. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

- **optimizer** [string or callable, optional (default: “fmin_l_bfgs_b”)] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:
def optimizer(obj_func, initial_theta, bounds):
    # 'obj_func' is the objective function to be minimized, which
    # takes the hyperparameters theta as parameter and an
    # optional flag eval_gradient, which determines if the
    # gradient is returned additionally to the function value
    # 'initial_theta': the initial value for theta, which can be
    # used by local optimizers
    # 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min

Per default, the ‘L-BFGSB’ algorithm from scipy.optimize.minimize is used. If None is
passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

'n_min_l_bfgs_b'

n_restarts_optimizer [int, optional (default: 0)] The number of restarts of the optimizer for
finding the kernel’s parameters which maximize the log-marginal likelihood. The first run
of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if
any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If
greater than 0, all bounds must be finite. Note that n_restarts_optimizer == 0 implies that
one run is performed.

normalize_y [boolean, optional (default: False)] Whether the target values y are normalized,
i.e., the mean of the observed target values become zero. This parameter should be set to
True if the target values’ mean is expected to differ considerable from zero. When enabled,
the normalization effectively modifies the GP’s prior based on the data, which contradicts
the likelihood principle; normalization is thus disabled per default.

copy_X_train [bool, optional (default: True)] If True, a persistent copy of the training data is
stored in the object. Otherwise, just a reference to the training data is stored, which might
cause predictions to change if the data is modified externally.

random_state [int, RandomState instance or None, optional (default: None)] The generator
used to initialize the centers. If int, random_state is the seed used by the random number
generator; If RandomState instance, random_state is the random number generator; If None,
the random number generator is the RandomState instance used by np.random.

Attributes

X_train_ [sequence of length n_samples] Feature vectors or other representations of training
data (also required for prediction). Could either be array-like with shape = (n_samples,
n_features) or a list of objects.

y_train_ [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values in training
data (also required for prediction)

kernel_ [kernel object] The kernel used for prediction. The structure of the kernel is the same
as the one passed as parameter but with optimized hyperparameters

L_ [array-like of shape (n_samples, n_samples)] Lower-triangular Cholesky decomposition of
the kernel in X_train_

alpha_ [array-like of shape (n_samples,)] Dual coefficients of training data points in kernel
space

log_marginal_likelihood_value_ [float] The log-marginal-likelihood of self.kernel_.
theta
Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel()
>>> gpr = GaussianProcessRegressor(kernel=kernel, random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:,2:], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

Methods

```python
fit(self, X, y)            Fit Gaussian process regression model.
get_params(self[, deep])   Get parameters for this estimator.
log_marginal_likelihood(self[, theta, ...]) Returns log-marginal likelihood of theta for training data.
predict(self, X[, return_std, return_cov]) Predict using the Gaussian process regression model
sample_y(self, X[, n_samples, random_state]) Draw samples from Gaussian process and evaluate at X.
score(self, X, y[, sample_weight]) Return the coefficient of determination R^2 of the prediction.
set_params(self, **params) Set the parameters of this estimator.
```

```
__init__(self, kernel=None, alpha=1e-10, optimizer='fmin_l_bfgs_b', n_restarts_optimizer=0, normalize_y=False, copy_X_train=True, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Fit Gaussian process regression model.

Parameters

X [sequence of length n_samples] Feature vectors or other representations of training data.
Could either be array-like with shape = (n_samples, n_features) or a list of objects.

y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values

Returns

self [returns an instance of self.]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
```
**log_marginal_likelihood** *(self, theta=None, eval_gradient=False, clone_kernel=True)*

Returns log-marginal likelihood of theta for training data.

**Parameters**

- **theta** [array-like of shape (n_kernel_params,) or None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed log_marginal_likelihood of self.kernel_.theta is returned.

- **eval_gradient** [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

- **clone_kernel** [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

**Returns**

- **log_likelihood** [float] Log-marginal likelihood of theta for training data.

- **log_likelihood_gradient** [array, shape = (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

**predict** *(self, X, return_std=False, return_cov=False)*

Predict using the Gaussian process regression model.

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (return_std=True) or covariance (return_cov=True). Note that at most one of the two can be requested.

**Parameters**

- **X** [sequence of length n_samples] Query points where the GP is evaluated. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

- **return_std** [bool, default: False] If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.

- **return_cov** [bool, default: False] If True, the covariance of the joint predictive distribution at the query points is returned along with the mean.

**Returns**

- **y_mean** [array, shape = (n_samples, [n_output_dims])] Mean of predictive distribution at query points

- **y_std** [array, shape = (n_samples,), optional] Standard deviation of predictive distribution at query points. Only returned when return_std is True.

- **y_cov** [array, shape = (n_samples, n_samples), optional] Covariance of joint predictive distribution at query points. Only returned when return_cov is True.

**sample_y** *(self, X, n_samples=1, random_state=0)*

Draw samples from Gaussian process and evaluate at X.

**Parameters**

- **X** [sequence of length n_samples] Query points where the GP is evaluated. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

- **n_samples** [int, default: 1] The number of samples drawn from the Gaussian process

- **random_state** [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance,
random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

y_samples [array, shape = (n_samples_X, [n_output_dims], n_samples)] Values of n_samples samples drawn from Gaussian process and evaluated at query points.

dscore (self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R^2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.gaussian_process.GaussianProcessRegressor

- Comparison of kernel ridge and Gaussian process regression
- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) with noise-level estimation
• Gaussian Processes regression: basic introductory example
• Gaussian process regression (GPR) on Mauna Loa CO2 data.
• Gaussian processes on discrete data structures

Kernels:

```python
gaussian_process.kernels.CompoundKernel(kernels)  # Kernel which is composed of a set of other kernels.
```

```python
gaussian_process.kernels.ConstantKernel([...])  # Constant kernel.
```

```python
gaussian_process.kernels.DotProduct([...])  # Dot-Product kernel.
```

```python
```

```python
gaussian_process.kernels.Exponentiation(...)  # Exponentiate kernel by given exponent.
```

```python
gaussian_process.kernels.Hyperparameter  # A kernel hyperparameter’s specification in form of a namedtuple.
```

```python
gaussian_process.kernels.Kernel  # Base class for all kernels.
```

```python
gaussian_process.kernels.Matern([...])  # Matern kernel.
```

```python
gaussian_process.kernels.PairwiseKernel([...])  # Wrapper for kernels in sklearn.metrics.pairwise.
```

```python
gaussian_process.kernels.Product(k1, k2)  # Product-kernel k1 * k2 of two kernels k1 and k2.
```

```python
gaussian_process.kernels.RBF([length_scale, ...])  # Radial-basis function kernel (aka squared-exponential kernel).
```

```python
gaussian_process.kernels.RationalQuadratic([...])  # Rational Quadratic kernel.
```

```python
gaussian_process.kernels.Sum(k1, k2)  # Sum-kernel k1 + k2 of two kernels k1 and k2.
```

```python
gaussian_process.kernels.WhiteKernel([...])  # White kernel.
```

7.16.3 sklearn.gaussian_process.kernels.CompoundKernel

```python
class sklearn.gaussian_process.kernels.CompoundKernel(kernels)  
Kernel which is composed of a set of other kernels.
```

New in version 0.18.

Parameters

- **kernels** [list of Kernel objects] The other kernels

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on discrete structures.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.
Methods

__call__(self, X[, Y , eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(self, theta) Returns a clone of self with given hyperparameters theta.

diag(self, X) Returns the diagonal of the kernel k(X, X).

get_params(self[, deep]) Get parameters of this kernel.

is_stationary(self) Returns whether the kernel is stationary.

set_params(self, **params) Set the parameters of this kernel.

__init__(self, kernels) Initialize self. See help(type(self)) for accurate signature.

__call__(self, X, Y=None, eval_gradient=False) Return the kernel k(X, Y) and optionally its gradient.

Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

K [array, shape (n_samples_X, n_samples_Y, n_kernels)] Kernel k(X, Y)

K_gradient [array, shape (n_samples_X, n_samples_X, n_dims, n_kernels)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds

Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (self, theta) Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (self, X) Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X, n_kernels)] Diagonal of kernel k(X, X)

get_params (self, deep=True)
Get parameters of this kernel.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary (self)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on discrete structures.

set_params (self, **params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.4 sklearn.gaussian_process.kernels.ConstantKernel

class sklearn.gaussian_process.kernels.ConstantKernel (constant_value=1.0, constant_value_bounds=(1e-05, 100000.0))

Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a sum-kernel, where it modifies the mean of the Gaussian process.

k(x_1, x_2) = constant_value for all x_1, x_2
New in version 0.18.

Parameters

- **constant_value** [float, default: 1.0] The constant value which defines the covariance: \( k(x_1, x_2) = constant_value \)

- **constant_value_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on constant_value

Attributes

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_constant_value**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.

- **requires_vector_input** Whether the kernel works only on fixed-length feature vectors.

- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**__init__**(self, constant_value=1.0, constant_value_bounds=(1e-05, 100000.0))

Initialize self. See help(type(self)) for accurate signature.

**__call__**(self, X, Y=None, eval_gradient=False)

Return the kernel \( k(X, Y) \) and optionally its gradient.

Parameters

- **X** [sequence of length n_samples_X] Left argument of the returned kernel \( k(X, Y) \). Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

- **Y** [sequence of length n_samples_Y] Right argument of the returned kernel \( k(X, Y) \). If None, \( k(X, X) \) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

- **eval_gradient** [bool (optional, default=\[False\])] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel \( k(X, Y) \)

- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel \( k(X, X) \) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.
**property bounds**

Returns the log-transformed bounds on the theta.

**Returns**

**bounds**  
[array, shape (n_dims, 2)]  
The log-transformed bounds on the kernel’s hyperparameters theta.

**clone_with_theta**  
*(self, theta)*  

Returns a clone of self with given hyperparameters theta.

**Parameters**

**theta**  
[array, shape (n_dims,)]  
The hyperparameters

**diag**  
*(self, X)*  

Returns the diagonal of the kernel $k(X, X)$.

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X**  
[sequence of length n_samples_X]  
Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

**Returns**

**K_diag**  
[array, shape (n_samples_X,)]  
Diagonal of kernel $k(X, X)$

**get_params**  
*(self, deep=**True**)*  

Get parameters of this kernel.

**Parameters**

**deep**  
[boolean, optional]  
If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params**  
[mapping of string to any]  
Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter specifications.

**is_stationary**  
*(self)*  

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Whether the kernel works only on fixed-length feature vectors.

**set_params**  
*(self, **params)*  

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

**self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta  [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.ConstantKernel

- Iso-probability lines for Gaussian Processes classification (GPC)
- Gaussian Processes regression: basic introductory example

7.16.5 sklearn.gaussian_process.kernels.DotProduct

class sklearn.gaussian_process.kernels.DotProduct (sigma_0=1.0, sigma_0_bounds=(1e-05, 100000.0))

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting N(0, 1) priors on the coefficients of x_d (d = 1, . . . , D) and a prior of N(0, sigma_0^2) on the bias. The DotProduct kernel is invariant to a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter sigma_0^2. For sigma_0^2 =0, the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

\[ k(x_i, x_j) = \sigma_0^2 + x_i \cdot x_j \]

The DotProduct kernel is commonly combined with exponentiation.

New in version 0.18.

Parameters

sigma_0  [float >= 0, default: 1.0] Parameter controlling the inhomogenity of the kernel. If sigma_0=0, the kernel is homogenous.

sigma_0_bounds  [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on l

Attributes

bounds  Returns the log-transformed bounds on the theta.

hyperparameter_sigma_0

hyperparameters  Returns a list of all hyperparameter specifications.

n_dims  Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input  Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta  Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods
__call__ (self, X[, Y, eval_gradient])  Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta (self, theta)  Returns a clone of self with given hyperparameters theta.

diag (self, X)  Returns the diagonal of the kernel k(X, X).

get_params (self[, deep])  Get parameters of this kernel.

is_stationary (self)  Returns whether the kernel is stationary.

set_params (self, **params)  Set the parameters of this kernel.

__init__ (self, sigma_0=1.0, sigma_0_bounds=(1e-05, 100000.0))  Initialize self. See help(type(self)) for accurate signature.

__call__ (self, X, Y=None, eval_gradient=False)  Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)]  Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)]  Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)]  Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)]  Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)]  The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds  Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)]  The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (self, theta)  Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)]  The hyperparameters

diag (self, X)  Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array, shape (n_samples_X, n_features)]  Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)]  Diagonal of kernel k(X, X)

get_params (self, deep=True)  Get parameters of this kernel.
Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

property hyperparameters

Returns a list of all hyperparameter specifications.

is_stationary(self)

Returns whether the kernel is stationary.

property n_dims

Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input

Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(self, **params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

property theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.DotProduct`

- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Illustration of prior and posterior Gaussian process for different kernels
- Iso-probability lines for Gaussian Processes classification (GPC)

7.16.6 `sklearn.gaussian_process.kernels.ExpSineSquared`

```python
class sklearn.gaussian_process.kernels.ExpSineSquared(length_scale=1.0, periodicity=1.0, length_scale_bounds=(1e-05, 100000.0), periodicity_bounds=(1e-05, 100000.0))
```

Exp-Sine-Squared kernel.
The ExpSineSquared kernel allows modeling periodic functions. It is parameterized by a length-scale parameter `length_scale>0` and a periodicity parameter `periodicity>0`. Only the isotropic variant where `l` is a scalar is supported at the moment. The kernel given by:

\[ k(x_i, x_j) = \exp(-2 \left( \sin(\pi / periodicity \cdot d(x_i, x_j)) / length_scale \right)^2) \]

New in version 0.18.

**Parameters**

- `length_scale` [float > 0, default: 1.0] The length scale of the kernel.
- `periodicity` [float > 0, default: 1.0] The periodicity of the kernel.
- `length_scale_bounds` [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on `length_scale`
- `periodicity_bounds` [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on `periodicity`

**Attributes**

- `bounds` Returns the log-transformed bounds on the theta.
- `hyperparameter_length_scale`
- `hyperparameter_periodicity`
- `hyperparameters` Returns a list of all hyperparameter specifications.
- `n_dims` Returns the number of non-fixed hyperparameters of the kernel.
- `requires_vector_input` Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- `theta` Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

- `__call__(self, X[, Y , eval_gradient])` Return the kernel `k(X, Y)` and optionally its gradient.
- `clone_with_theta(self, theta)` Returns a clone of self with given hyperparameters theta.
- `diag(self, X)` Returns the diagonal of the kernel `k(X, X)`.
- `get_params(self[, deep])` Get parameters of this kernel.
- `is_stationary(self)` Returns whether the kernel is stationary.
- `set_params(self, \^{\text{*params}})` Set the parameters of this kernel.

```python
__init__(self, length_scale=1.0, periodicity=1.0, length_scale_bounds=(1e-05, 100000.0), periodicity_bounds=(1e-05, 100000.0))
```

Initialize self. See help(type(self)) for accurate signature.

```python
__call__(self, X=None, Y=None, eval_gradient=False)
```

Return the kernel `k(X, Y)` and optionally its gradient.

**Parameters**

- `X` [array, shape (n_samples_X, n_features)] Left argument of the returned kernel `k(X, Y)`
- `Y` [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel `k(X, Y)`. If None, `k(X, X)` if evaluated instead.
- `eval_gradient` [bool (optional, default=False)] Determines whether the gradient with re-
spect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
    Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

close_with_theta (self, theta)
    Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (self, X)
    Returns the diagonal of the kernel k(X, X).

    The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (self, deep=True)
    Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
    Returns a list of all hyperparameter specifications.

is_stationary (self)
    Returns whether the kernel is stationary.

property n_dims
    Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
    Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.
**set_params** *(self, **params)*

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

**Examples using sklearn.gaussian_process.kernels.ExpSineSquared**

- Comparison of kernel ridge and Gaussian process regression
- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

### 7.16.7 sklearn.gaussian_process.kernels.Exponentiation

**class** sklearn.gaussian_process.kernels.Exponentiation *(kernel, exponent)*

Exponentiate kernel by given exponent.

The resulting kernel is defined as $k_{\text{exp}}(X, Y) = k(X, Y)^{\text{exponent}}$

New in version 0.18.

**Parameters**

- **kernel** [Kernel object] The base kernel
- **exponent** [float] The exponent for the base kernel

**Attributes**

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on discrete structures.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

**__call__**(self, X[, Y, eval_gradient])

Return the kernel $k(X, Y)$ and optionally its gradient.

__init__(self, kernel, exponent)

Initialize self. See help(type(self)) for accurate signature.

__call__(self, X, Y=None, eval_gradient=False)

Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y). Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.
- **Y** [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.
- **eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds

Returns the log-transformed bounds on the theta.

Returns

- **bounds** [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

`clone_with_theta(self, theta)`

Returns a clone of self with given hyperparameters theta.

Parameters

- **theta** [array, shape (n_dims,)] The hyperparameters

`diag(self, X)`

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

- **X** [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

- **K_diag** [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)
get_params (self, deep=True)
Get parameters of this kernel.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter.

is_stationary (self)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on discrete structures.

set_params (self, **params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.8 sklearn.gaussian_process.kernels.Hyperparameter

class sklearn.gaussian_process.kernels.Hyperparameter
A kernel hyperparameter’s specification in form of a namedtuple.

New in version 0.18.

Attributes

name [string] Alias for field number 0

value_type [string] Alias for field number 1

bounds [pair of floats >= 0 or “fixed”] Alias for field number 2

n_elements [int, default=1] Alias for field number 3

fixed [bool, default: None] Alias for field number 4
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>count(self, value, /)</code></td>
<td>Return number of occurrences of value.</td>
</tr>
<tr>
<td><code>index(self, value[, start, stop])</code></td>
<td>Return first index of value.</td>
</tr>
</tbody>
</table>

```python
__init__(self, /, *args, **kwargs)
```

Initialize self. See help(type(self)) for accurate signature.

```python
__call__(*args, **kwargs)
```

Call self as a function.

**property bounds**

Alias for field number 2

**property count**

Return number of occurrences of value.

**property fixed**

Alias for field number 4

```python
index(self, value, start=0, stop=9223372036854775807, /)
```

Return first index of value.

Raises ValueError if the value is not present.

**property n_elements**

Alias for field number 3

**property name**

Alias for field number 0

**property value_type**

Alias for field number 1

### Examples using `sklearn.gaussian_process.kernels.Hyperparameter`

- Gaussian processes on discrete data structures

### 7.16.9 sklearn.gaussian_process.kernels.Kernel

**class sklearn.gaussian_process.kernels.Kernel**

Base class for all kernels.

New in version 0.18.

**Attributes**

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.
Methods

__call__(self, X[, Y, eval_gradient]) Evaluate the kernel.

close_with_theta(self, theta) Returns a clone of self with given hyperparameters theta.

diag(self, X) Returns the diagonal of the kernel k(X, X).

get_params(self[, deep]) Get parameters of this kernel.

is_stationary(self) Returns whether the kernel is stationary.

set_params(self, \*\*params) Set the parameters of this kernel.

__init__(self, /, *args, **kwargs) Initialize self. See help(type(self)) for accurate signature.

abstract __call__(self, X, Y=None, eval_gradient=False) Evaluate the kernel.

property bounds Returns the log-transformed bounds on the theta.

    Returns

    bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (self, theta) Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

abstract diag (self, X) Returns the diagonal of the kernel k(X, X).

    The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (self, deep=True) Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters Returns a list of all hyperparameter specifications.

abstract is_stationary (self) Returns whether the kernel is stationary.
**property n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

**set_params**(self, **params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns
self

**property theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns
theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.Kernel

• Gaussian processes on discrete data structures

7.16.10 sklearn.gaussian_process.kernels.Matern
class sklearn.gaussian_process.kernels.Matern(length_scale=1.0,
length_scale_bounds=(1e-05, 100000.0),
u=1.5)

Matern kernel.

The class of Matern kernels is a generalization of the RBF and the absolute exponential kernel parameterized by an additional parameter nu. The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions).

See Rasmussen and Williams 2006, pp84 for details regarding the different variants of the Matern kernel.

New in version 0.18.

Parameters

- **length_scale** [float or array with shape (n_features,), default: 1.0] The length scale of the kernel.
  If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

- **length_scale_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

- **nu** [float, default: 1.5] The parameter nu controlling the smoothness of the learned function.
  The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions).
differentiable functions). Note that values of nu not in \([0.5, 1.5, 2.5, \text{inf}]\) incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to \(l\), nu is kept fixed to its initial value and not optimized.

Attributes

- **anisotropic**
- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_length_scale**
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

- **__call__**(self, X[, Y, eval_gradient]) Return the kernel \(k(X, Y)\) and optionally its gradient.
- **clone_with_theta**(self, theta) Returns a clone of self with given hyperparameters theta.
- **diag**(self, X) Returns the diagonal of the kernel \(k(X, X)\).
- **get_params**(self[, deep]) Get parameters of this kernel.
- **is_stationary**(self) Returns whether the kernel is stationary.
- **set_params**(self, **params) Set the parameters of this kernel.

**__init__**(self, length_scale=1.0, length_scale_bounds=(1e-05, 100000.0), nu=1.5)

Initialize self. See help(type(self)) for accurate signature.

**__call__**(self, X, Y=None, eval_gradient=False)

Return the kernel \(k(X, Y)\) and optionally its gradient.

Parameters

- **X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \(k(X, Y)\)
- **Y** [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel \(k(X, Y)\). If None, \(k(X, X)\) if evaluated instead.

**eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when \(Y\) is None.

Returns

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel \(k(X, Y)\)
- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel \(k(X, X)\) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds**

Returns the log-transformed bounds on the theta.
bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

cancel_with_theta (self, theta)
Returns a clone of self with given hyperparameters theta.

Parameters
theta [array, shape (n_dims,)] The hyperparameters

diag (self, X)
Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns
K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (self, deep=True)
Get parameters of this kernel.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary (self)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (self, **params)
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.
Returns

theta  [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.Matern

- Illustration of prior and posterior Gaussian process for different kernels

7.16.11 sklearn.gaussian_process.kernels.PairwiseKernel

class sklearn.gaussian_process.kernels.PairwiseKernel (gamma=1.0,  
gamma_bounds=(1e-05, 100000.0), metric='linear',  
pairwise_kernels_kwargs=None)

Wrapper for kernels in sklearn.metrics.pairwise.

A thin wrapper around the functionality of the kernels in sklearn.metrics.pairwise.

Note: Evaluation of eval_gradient is not analytic but numeric and all kernels support only isotropic distances. The parameter gamma is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

Parameters

- gamma  [float >= 0, default: 1.0] Parameter gamma of the pairwise kernel specified by metric
- gamma_bounds  [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on gamma
- metric  [string, or callable, default: “linear”] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.
- pairwise_kernels_kwargs  [dict, default: None] All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.

Attributes

- bounds  Returns the log-transformed bounds on the theta.
- hyperparameter_gamma
- hyperparameters  Returns a list of all hyperparameter specifications.
- n_dims  Returns the number of non-fixed hyperparameters of the kernel.
- requires_vector_input  Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- theta  Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods
__call__(self, X[, Y, eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

circle_with_theta(self, theta) Returns a clone of self with given hyperparameters theta.

diag(self, X) Returns the diagonal of the kernel k(X, X).

get_params(self[, deep]) Get parameters of this kernel.

is_stationary(self) Returns whether the kernel is stationary.

set_params(self, **params) Set the parameters of this kernel.

__init__(self, gamma=1.0, gamma_bounds=(1e-05, 100000.0), metric='linear', pairwise_kernels_kwargs=None) Initialize self. See help(type(self)) for accurate signature.

__call__(self, X, Y=None, eval_gradient=False) Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(self, theta) Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters
diag(self, X) Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)
get_params (self, deep=True)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary (self)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True
for backward compatibility.

set_params (self, **params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.12 sklearn.gaussian_process.kernels.Product

class sklearn.gaussian_process.kernels.Product (k1, k2)
Product-kernel k1 * k2 of two kernels k1 and k2.
The resulting kernel is defined as k_prod(X, Y) = k1(X, Y) * k2(X, Y)
New in version 0.18.

Parameters

k1 [Kernel object] The first base-kernel of the product-kernel
k2 [Kernel object] The second base-kernel of the product-kernel

Attributes

bounds Returns the log-transformed bounds on the theta.
**hyperparameters** Returns a list of all hyperparameter.

**n_dims** Returns the number of non-fixed hyperparameters of the kernel.

**requires_vector_input** Returns whether the kernel is stationary.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

**__init__**(self, k1, k2) Initialize self. See help(type(self)) for accurate signature.

**__call__**(self, X, Y=None, eval_gradient=False) Return the kernel k(X, Y) and optionally its gradient.

**Parameters**

- **X** [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

- **Y** [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

- **eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

**Returns**

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds** Returns the log-transformed bounds on the theta.

**Returns**

- **bounds** [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(self, theta) Returns a clone of self with given hyperparameters theta.

**Parameters**

- **theta** [array, shape (n_dims,)] The hyperparameters

**diag**(self, X) Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- **X** [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

**Returns**

- **K_diag** [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

**get_params**(self, deep=True)

Get parameters of this kernel.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameters.

**is_stationary**(self)

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Returns whether the kernel is stationary.

**set_params**(self, **params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

- **theta** [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 7.16.13 sklearn.gaussian_process.kernels.RBF

**class sklearn.gaussian_process.kernels.RBF**(length_scale=1.0, length_scale_bounds=(1e-05, 100000.0))

Radial-basis function kernel (aka squared-exponential kernel).
The RBF kernel is a stationary kernel. It is also known as the “squared exponential” kernel. It is parameterized by a length-scale parameter length_scale>0, which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs X (anisotropic variant of the kernel). The kernel is given by:

\[ k(x_i, x_j) = \exp(-1 / 2 \frac{d(x_i / \text{length}_\text{scale}, x_j / \text{length}_\text{scale})^2}{2}) \]

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth.

New in version 0.18.

**Parameters**

- **length_scale** [float or array with shape (n_features,), default: 1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

- **length_scale_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

**Attributes**

- **anisotropic**

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_length_scale**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.

- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

- **__call__(self, X[, Y, eval_gradient])** Return the kernel \(k(X, Y)\) and optionally its gradient.

- **clone_with_theta(self, theta)** Returns a clone of self with given hyperparameters theta.

- **diag(self, X)** Returns the diagonal of the kernel \(k(X, X)\).

- **get_params(self[, deep])** Get parameters of this kernel.

- **is_stationary(self)** Returns whether the kernel is stationary.

- **set_params(self, \*\*params)** Set the parameters of this kernel.

- **__init__(self, length_scale=1.0, length_scale_bounds=(1e-05, 100000.0))** Initialize self. See help(type(self)) for accurate signature.

- **__call__(self, X, Y=None, eval_gradient=False)** Return the kernel \(k(X, Y)\) and optionally its gradient.

**Parameters**

- **X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \(k(X, Y)\)

- **Y** [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel \(k(X, Y)\). If None, \(k(X, Y)\) if evaluated instead.
**eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

**Returns**

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- **bounds** [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(self, theta)

Returns a clone of self with given hyperparameters theta.

**Parameters**

- **theta** [array, shape (n_dims,)] The hyperparameters

**diag**(self, X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- **X** [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

**Returns**

- **K_diag** [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

**get_params**(self, deep=True)

Get parameters of this kernel.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter specifications.

**is_stationary**(self)

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.
**set_params**(*self, **params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
`<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

`sself`

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

**Returns**

`theta [array, shape (n_dims,)]` The non-fixed, log-transformed hyperparameters of the kernel

---

**Examples using sklearn.gaussian_process.kernels.RBF**

- Plot classification probability
- Classifier comparison
- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Gaussian process classification (GPC) on iris dataset
- Illustration of prior and posterior Gaussian process for different kernels
- Probabilistic predictions with Gaussian process classification (GPC)
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian Processes regression: basic introductory example
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

---

**7.16.14 sklearn.gaussian_process.kernels.RationalQuadratic**

```python
class sklearn.gaussian_process.kernels.RationalQuadratic(length_scale=1.0,
                        alpha=1.0,
                        length_scale_bounds=(1e-05, 100000.0),
                        alpha_bounds=(1e-05, 100000.0))
```

Rational Quadratic kernel.

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different
characteristic length-scales. It is parameterized by a length-scale parameter length_scale>0 and a scale mixture
parameter alpha>0. Only the isotropic variant where length_scale is a scalar is supported at the moment. The
kernel given by:

\[
k(x_i, x_j) = (1 + d(x_i, x_j)^2 / (2 * alpha * length_scale^2))^{-alpha}
\]

New in version 0.18.

**Parameters**

- `length_scale` [float > 0, default: 1.0] The length scale of the kernel.
alpha [float > 0, default: 1.0] Scale mixture parameter

length_scale_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

alpha_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on alpha

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_alpha

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y , eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(self, theta) Returns a clone of self with given hyperparameters theta.

diag(self, X) Returns the diagonal of the kernel k(X, X).

geta_params(self[, deep]) Get parameters of this kernel.

is_stationary(self) Returns whether the kernel is stationary.

set_params(self, \*\*params) Set the parameters of this kernel.

__init__(self, length_scale=1.0, alpha=1.0, length_scale_bounds=(1e-05, 1e500000.0), alpha_bounds=(1e-05, 100000.0)) Initialize self. See help(type(self)) for accurate signature.

call__(self, X,Y=None, eval_gradient=False) Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds

Returns the log-transformed bounds on the theta.
Returns

    bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (self, theta)
    Returns a clone of self with given hyperparameters theta.

Parameters

    theta [array, shape (n_dims,)] The hyperparameters

diag (self, X)
    Returns the diagonal of the kernel k(X, X).

    The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

    X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

    K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (self, deep=True)
    Get parameters of this kernel.

Parameters

    deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

    params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
    Returns a list of all hyperparameter specifications.

is_stationary (self)
    Returns whether the kernel is stationary.

property n_dims
    Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
    Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (self, **params)
    Set the parameters of this kernel.

    The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

    self

property theta
    Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta  [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.RationalQuadratic

- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.16.15 sklearn.gaussian_process.kernels.Sum

class sklearn.gaussian_process.kernels.Sum(k1, k2)
Sum-kernel k1 + k2 of two kernels k1 and k2.

The resulting kernel is defined as $k_{sum}(X, Y) = k1(X, Y) + k2(X, Y)$

New in version 0.18.

Parameters

k1  [Kernel object] The first base-kernel of the sum-kernel

k2  [Kernel object] The second base-kernel of the sum-kernel

Attributes

bounds  Returns the log-transformed bounds on the theta.

hyperparameters  Returns a list of all hyperparameter.

n_dims  Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input  Returns whether the kernel is stationary.

theta  Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(self, theta) Returns a clone of self with given hyperparameters theta.

diag(self, X) Returns the diagonal of the kernel k(X, X).

get_params(self[, deep]) Get parameters of this kernel.

is_stationary(self) Returns whether the kernel is stationary.

set_params(self, **params) Set the parameters of this kernel.

__init__(self, k1, k2)
Initialize self. See help(type(self)) for accurate signature.

__call__(self, X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters
X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

close_with_theta (self, theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters
diag (self, X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (self, deep=True)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter.

is_stationary (self)
Returns whether the kernel is stationary.
property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is stationary.

set_params(self, **params)
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

Returns
theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel.

7.16.16 sklearn.gaussian_process.kernels.WhiteKernel

class sklearn.gaussian_process.kernels.WhiteKernel(noise_level=1.0,
noise_level_bounds=(1e-05, 100000.0))
White kernel.
The main use-case of this kernel is as part of a sum-kernel where it explains the noise of the signal as indepen-
dently and identically normally-distributed. The parameter noise_level equals the variance of this noise.
k(x_1, x_2) = noise_level if x_1 == x_2 else 0
New in version 0.18.

Parameters

noise_level [float, default: 1.0] Parameter controlling the noise level (variance)
noise_level_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on
noise_level

Attributes

bounds Returns the log-transformed bounds on the theta.
hyperparameter_noise_level
hyperparameters Returns a list of all hyperparameter specifications.
n_dims Returns the number of non-fixed hyperparameters of the kernel.
requires_vector_input Whether the kernel works only on fixed-length feature vectors.
theta Returns the (flattened, log-transformed) non-fixed hyperparameters.
Methods

__call__(self, X[, Y, eval_gradient])  Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(self, theta)  Returns a clone of self with given hyperparameters theta.

diag(self, X)  Returns the diagonal of the kernel k(X, X).

get_params(self[, deep])  Get parameters of this kernel.

is_stationary(self)  Returns whether the kernel is stationary.

set_params(self, **params)  Set the parameters of this kernel.

__init__(self, noise_level=1.0, noise_level_bounds=(1e-05, 100000.0))  Initialize self. See help(type(self)) for accurate signature.

__call__(self, X, Y=None, eval_gradient=False)  Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds  Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(self, theta)  Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(self, X)  Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.
Returns

\texttt{K\_diag} [array, shape (n\_samples\_X,)] Diagonal of kernel k(X, X)

\texttt{get\_params}(self, deep=True)
Get parameters of this kernel.

Parameters

deepl [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

\texttt{params} [mapping of string to any] Parameter names mapped to their values.

\textit{property hyperparameters}
Returns a list of all hyperparameter specifications.

\textit{is\_stationary}(self)
Returns whether the kernel is stationary.

\textit{property n\_dims}
Returns the number of non-fixed hyperparameters of the kernel.

\textit{property requires\_vector\_input}
Whether the kernel works only on fixed-length feature vectors.

\textit{set\_params}(self, **params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form \texttt{<component>\_<parameter>\_} so that it’s possible to update each component of a nested object.

Returns

self

\textit{property theta}
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

\texttt{theta} [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel.

Examples using \texttt{sklearn.gaussian\_process\_kernels.WhiteKernel}

- Comparison of kernel ridge and Gaussian process regression
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.17 \texttt{sklearn.impute: Impute}

Transformers for missing value imputation

User guide: See the \textit{Imputation of missing values} section for further details.
**7.17.1 sklearn.impute.SimpleImputer**

```python
class sklearn.impute.SimpleImputer(missing_values=np.nan, strategy='mean', fill_value=None, verbose=0, copy=True, add_indicator=False)
```

Imputation transformer for completing missing values.

Read more in the [User Guide](#).

**Parameters**

- **missing_values** [number, string, np.nan (default) or None] The placeholder for the missing values. All occurrences of missing_values will be imputed.

- **strategy** [string, default='mean'] The imputation strategy.
  - If “mean”, then replace missing values using the mean along each column. Can only be used with numeric data.
  - If “median”, then replace missing values using the median along each column. Can only be used with numeric data.
  - If “most_frequent”, then replace missing using the most frequent value along each column. Can be used with strings or numeric data.
  - If “constant”, then replace missing values with fill_value. Can be used with strings or numeric data.

New in version 0.20: strategy="constant" for fixed value imputation.

- **fill_value** [string or numerical value, default=None] When strategy == “constant”, fill_value is used to replace all occurrences of missing_values. If left to the default, fill_value will be 0 when imputing numerical data and “missing_value” for strings or object data types.

- **verbose** [integer, default=0] Controls the verbosity of the imputer.

- **copy** [boolean, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if copy=False:
  - If X is not an array of floating values;
  - If X is encoded as a CSR matrix;
  - If add_indicator=True.

- **add_indicator** [boolean, default=False] If True, a MissingIndicator transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

**Attributes**
statistics_ [array of shape (n_features,)] The imputation fill value for each feature. Computing statistics can result in \texttt{np.nan} values. During \texttt{transform}, features corresponding to \texttt{np.nan} statistics will be discarded.

indicator_ [sklearn.impute.MissingIndicator] Indicator used to add binary indicators for missing values. \texttt{None} if \texttt{add_indicator} is False.

See also:

\texttt{IterativeImputer} Multivariate imputation of missing values.

Notes

Columns which only contained missing values at \texttt{fit} are discarded upon \texttt{transform} if strategy is not “constant”.

Examples

```python
>>> import numpy as np
>>> from sklearn.impute import SimpleImputer
>>> imp_mean = SimpleImputer(missing_values=np.nan, strategy='mean')
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
SimpleImputer()
>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> print(imp_mean.transform(X))
[[ 7.  2.  3.]
 [ 4.  3.5  6.]
 [10.  3.5  9.]]
```

Methods

- \texttt{fit}(self, X[, y]) Fit the imputer on X.
- \texttt{fit_transform}(self, X[, y]) Fit to data, then transform it.
- \texttt{get_params}(self[, deep]) Get parameters for this estimator.
- \texttt{set_params}(self, **params) Set the parameters of this estimator.
- \texttt{transform}(self, X) Impute all missing values in X.

\texttt{__init__}(self, \texttt{missing_values=}nan, \texttt{strategy=}’mean’, \texttt{fill_value=}None, \texttt{verbose=}0, \texttt{copy=}True, \texttt{add_indicator=}False)

Initialize self. See help(type(self)) for accurate signature.

\texttt{fit}(self, X, y=None)

Fit the imputer on X.

Parameters

- \texttt{X} [[array-like, sparse matrix], shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

Returns

- \texttt{self} [SimpleImputer]

\texttt{fit_transform}(self, X, y=None, **fit_params)

Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*

Impute all missing values in X.

**Parameters**

- **X** [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

**Examples using sklearn.impute.SimpleImputer**

- Permutation Importance vs Random Forest Feature Importance (MDI)
- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
- Column Transformer with Mixed Types
7.17.2 sklearn.impute.IterativeImputer

```python
class sklearn.impute.IterativeImputer(  
estimator=None,  
missing_values=np.nan,  
sample_posterior=False,  
max_iter=10,  
tol=0.001,  
n_nearest_features=None,  
initial_strategy='mean',  
imputation_order='ascending',  
skip_complete=False,  
min_value=None,  
max_value=None,  
verbose=0,  
random_state=None,  
add_indicator=False)
```

Multivariate imputer that estimates each feature from all the others.

A strategy for imputing missing values by modeling each feature with missing values as a function of other features in a round-robin fashion.

Read more in the User Guide.

**Note:** This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_iterative_imputer`:

```python
>>> from sklearn.experimental import enable_iterative_imputer  
>>> from sklearn.impute import IterativeImputer
```

### Parameters

- **estimator** [estimator object, default=BayesianRidge()] The estimator to use at each step of the round-robin imputation. If `sample_posterior` is True, the estimator must support `return_std` in its `predict` method.

- **missing_values** [int, np.nan, default=np.nan] The placeholder for the missing values. All occurrences of `missing_values` will be imputed.

- **sample_posterior** [boolean, default=False] Whether to sample from the (Gaussian) predictive posterior of the fitted estimator for each imputation. Estimator must support `return_std` in its `predict` method if set to True. Set to True if using `IterativeImputer` for multiple imputations.

- **max_iter** [int, default=10] Maximum number of imputation rounds to perform before returning the imputations computed during the final round. A round is a single imputation of each feature with missing values. The stopping criterion is met once `abs(max(X_t - X_{t-1}))/abs(max(X[known_vals])) < tol`, where `X_t` is `X` at iteration `t`. Note that early stopping is only applied if `'sample_posterior=False'`.

- **tol** [float, default=1e-3] Tolerance of the stopping condition.

- **n_nearest_features** [int, default=None] Number of other features to use to estimate the missing values of each feature column. Nearness between features is measured using the absolute correlation coefficient between each feature pair (after initial imputation). To ensure coverage of features throughout the imputation process, the neighbor features are not necessarily nearest, but are drawn with probability proportional to correlation for each imputed target feature. Can provide significant speed-up when the number of features is huge. If None, all features will be used.

- **initial_strategy** [str, default='mean'] Which strategy to use to initialize the missing values. Same as the `strategy` parameter in `sklearn.impute.SimpleImputer` Valid values: {“mean”, “median”, “most_frequent”, or “constant”}.
imputation_order  [str, default='ascending'] The order in which the features will be imputed. Possible values:

“ascending” From features with fewest missing values to most.
“descending” From features with most missing values to fewest.
“roman” Left to right.
“arabic” Right to left.
“random” A random order for each round.

skip_complete  [boolean, default=False] If True then features with missing values during transform which did not have any missing values during fit will be imputed with the initial imputation method only. Set to True if you have many features with no missing values at both fit and transform time to save compute.

min_value  [float, default=None] Minimum possible imputed value. Default of None will set minimum to negative infinity.

max_value  [float, default=None] Maximum possible imputed value. Default of None will set maximum to positive infinity.

verbose  [int, default=0] Verbosity flag, controls the debug messages that are issued as functions are evaluated. The higher, the more verbose. Can be 0, 1, or 2.

random_state  [int, RandomState instance or None, default=None] The seed of the pseudo random number generator to use. Randomizes selection of estimator features if n_nearest_features is not None, the imputation_order if random, and the sampling from posterior if sample_posterior is True. Use an integer for determinism. See the Glossary.

add_indicator  [boolean, default=False] If True, a MissingIndicator transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

Attributes

initial_imputer_  [object of type sklearn.impute.SimpleImputer] Imputer used to initialize the missing values.

imputation_sequence_  [list of tuples] Each tuple has (feat_idx, neighbor_feat_idx, estimator), where feat_idx is the current feature to be imputed, neighbor_feat_idx is the array of other features used to impute the current feature, and estimator is the trained estimator used for the imputation. Length is self.n_features_with_missing_ * self.n_iter_.

n_iter_  [int] Number of iteration rounds that occurred. Will be less than self.max_iter if early stopping criterion was reached.

n_features_with_missing_  [int] Number of features with missing values.

indicator_  [sklearn.impute.MissingIndicator] Indicator used to add binary indicators for missing values. None if add_indicator is False.

random_state_  [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by np.random.

See also:
**SimpleImputer** Univariate imputation of missing values.

**Notes**

To support imputation in inductive mode we store each feature’s estimator during the *fit* phase, and predict without refitting (in order) during the *transform* phase.

Features which contain all missing values at *fit* are discarded upon *transform*.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.experimental import enable_iterative_imputer
>>> from sklearn.impute import IterativeImputer

>>> imp_mean = IterativeImputer(random_state=0)

>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
IterativeImputer(random_state=0)

>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]

>>> imp_mean.transform(X)
aRRray([[ 6.9584..., 2. , 3. ]
[ 4. , 2.6000..., 6. ]
[10. , 4.9999..., 9. ]])
```

**Methods**

- `fit(self, X[, y])` Fits the imputer on X and return self.
- `fit_transform(self, X[, y])` Fits the imputer on X and return the transformed X.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Imputes all missing values in X.

```python
__init__(self, estimator=None, missing_values=np.nan, sample_posterior=False, max_iter=10, tol=0.001, n_nearest_features=None, initial_strategy='mean', imputation_order='ascending', skip_complete=False, min_value=None, max_value=None, verbose=0, random_state=None, add_indicator=False)
```

Initialize self. See help(type(self)) for accurate signature.

- `fit (self, X, y=None)`

  Fits the imputer on X and return self.

  **Parameters**

  - **X** [array-like, shape (n_samples, n_features)] Input data, where “n_samples” is the number of samples and “n_features” is the number of features.

  - **y** [ignored]

  **Returns**

  - **self** [object] Returns self.
**fit_transform** *(self, X, y=None)*
Fits the imputer on X and return the transformed X.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Input data, where “n_samples” is the number of samples and “n_features” is the number of features.
- **y** [ignored.]

**Returns**

- **Xt** [array-like, shape (n_samples, n_features)] The imputed input data.

**get_params** *(self, deep=True)*
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*
Imputes all missing values in X.

Note that this is stochastic, and that if random_state is not fixed, repeated calls, or permuted input, will yield different results.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The input data to complete.

**Returns**

- **Xt** [array-like, shape (n_samples, n_features)] The imputed input data.

**Examples using sklearn.impute.IterativeImputer**

- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
7.17.3 `sklearn.impute.MissingIndicator`

class `sklearn.impute.MissingIndicator`(missing_values=nan, features='missing-only', sparse='auto', error_on_new=True)

Binary indicators for missing values.

Note that this component typically should not be used in a vanilla `Pipeline` consisting of transformers and a classifier, but rather could be added using a `FeatureUnion` or `ColumnTransformer`.

Read more in the User Guide.

Parameters

*missing_values* [number, string, np.nan (default) or None] The placeholder for the missing values. All occurrences of `missing_values` will be indicated (True in the output array), the other values will be marked as False.

*features* [str, default=None] Whether the imputer mask should represent all or a subset of features.

  - If “missing-only” (default), the imputer mask will only represent features containing missing values during fit time.

  - If “all”, the imputer mask will represent all features.

*sparse* [boolean or “auto”, default=None] Whether the imputer mask format should be sparse or dense.

  - If “auto” (default), the imputer mask will be of same type as input.

  - If True, the imputer mask will be a sparse matrix.

  - If False, the imputer mask will be a numpy array.

*error_on_new* [boolean, default=None] If True (default), transform will raise an error when there are features with missing values in transform that have no missing values in fit. This is applicable only when `features="missing-only"`.

Attributes

*features_* [ndarray, shape (n_missing_features,) or (n_features,)] The features indices which will be returned when calling `transform`. They are computed during `fit`. For `features='all'`, it is to range(n_features).

Examples

```python
>>> import numpy as np
>>> from sklearn.impute import MissingIndicator
>>> X1 = np.array([[np.nan, 1, 3],
...                 [4, 0, np.nan],
...                 [8, 1, 0]])
>>> X2 = np.array([[5, 1, np.nan],
...                 [np.nan, 2, 3],
...                 [2, 4, 0]])
>>> indicator = MissingIndicator()
>>> indicator.fit(X1)
MissingIndicator()
>>> X2_tr = indicator.transform(X2)
>>> X2_tr
array([[False,  True],
       [False, True],
       [ True, False]])
```

Methods

**fit**(self, X[, y]) Fit the transformer on X.

**fit_transform**(self, X[, y]) Generate missing values indicator for X.

**get_params**(self[, deep]) Get parameters for this estimator.

**set_params**(self, **params) Set the parameters of this estimator.

**transform**(self, X) Generate missing values indicator for X.

---

__init__ (self, missing_values=nan, features='missing-only', sparse='auto', error_on_new=True) Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y=None) Fit the transformer on X.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) Input data, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **self** [object] Returns self.

**fit_transform**(self, X, y=None) Generate missing values indicator for X.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) The input data to complete.

**Returns**

- **Xt** [ndarray or sparse matrix, shape (n_samples, n_features) or (n_samples, n_features_with_missing)] The missing indicator for input data. The data type of Xt will be boolean.

**get_params**(self, deep=True) Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params**(self, **params) Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

---
**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform** (self, X)

Generate missing values indicator for X.

**Parameters**

X [([array-like, sparse matrix], shape (n_samples, n_features))] The input data to complete.

**Returns**

Xt [([ndarray or sparse matrix], shape (n_samples, n_features) or (n_samples, n_features_with_missing))] The missing indicator for input data. The data type of xt will be boolean.

**Examples using sklearn.impute.MissingIndicator**

- Imputing missing values before building an estimator

**7.17.4 sklearn.impute.KNNImputer**

**class** sklearn.impute.KNNImputer (missing_values=nan, n_neighbors=5, weights='uniform', metric='nan_euclidean', copy=True, add_indicator=False)

Imputation for completing missing values using k-Nearest Neighbors.

Each sample’s missing values are imputed using the mean value from n_neighbors nearest neighbors found in the training set. Two samples are close if the features that neither is missing are close.

Read more in the User Guide.

New in version 0.22.

**Parameters**

missing_values [number, string, np.nan or None, default=’np.nan’] The placeholder for the missing values. All occurrences of missing_values will be imputed.

n_neighbors [int, default=5] Number of neighboring samples to use for imputation.

weights [‘uniform’, ‘distance’] or callable, default=’uniform’) Weight function used in prediction. Possible values:

• ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.

• ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.

• callable : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

metric [‘nan_euclidean’) or callable, default=’nan_euclidean’) Distance metric for searching neighbors. Possible values:

• ‘nan_euclidean’

• callable : a user-defined function which conforms to the definition of _pairwise_callable(X, Y, metric, **kwds). The function accepts two arrays, X and Y, and a missing_values keyword in kwds and returns a scalar distance value.
copy [bool, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible.

add_indicator [bool, default=False] If True, a MissingIndicator transform will stack onto the output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

Attributes

indicator_ [sklearn.impute.MissingIndicator] Indicator used to add binary indicators for missing values. None if add_indicator is False.

Examples

```python
>>> import numpy as np
>>> from sklearn.impute import KNNImputer
>>> X = [[1, 2, np.nan], [3, 4, 3], [np.nan, 6, 5], [8, 8, 7]]
>>> imputer = KNNImputer(n_neighbors=2)
>>> imputer.fit_transform(X)
array([[1., 2., 4.],
       [3., 4., 3.],
       [5.5, 6., 5.],
       [8., 8., 7.]])
```

Methods

- `fit(self, X[, y])` Fit the imputer on X.
- `fit_transform(self, X[, y])` Fit to data, then transform it.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Impute all missing values in X.

```python
__init__(self, missing_values=nan, n_neighbors=5, weights='uniform', metric='nan_euclidean', copy=True, add_indicator=False)
```

Initialize self. See help(type(self)) for accurate signature.

- `fit (self, X, y=None)` Fit the imputer on X.

Parameters

- `X` [array-like shape of (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

Returns

- `self` [object]
**fit_transform** *(self, X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*

Impute all missing values in X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The input data to complete.

**Returns**

- **X** [array-like of shape (n_samples, n_output_features)] The imputed dataset. _n_output_features_ is the number of features that is not always missing during fit.

---

**Examples using `sklearn.impute.KNNImputer`**

- *Imputing missing values before building an estimator*
- *Release Highlights for scikit-learn 0.22*
The `sklearn.inspection` module includes tools for model inspection.

```python
inspection.partial_dependence(estimator, X, ...)  # Partial dependence of features.

inspection.permutation_importance(estimator, ...)  # Permutation importance for feature evaluation [BRE].
```

### 7.18.1 sklearn.inspection.partial_dependence

```python
sklearn.inspection.partial_dependence(estimator, X, features, response_method='auto', percentiles=(0.05, 0.95), grid_resolution=100, method='auto')
```

Partial dependence of features.

Partial dependence of a feature (or a set of features) corresponds to the average response of an estimator for each possible value of the feature.

Read more in the User Guide.

**Parameters**

- `estimator` [BaseEstimator] A fitted estimator object implementing `predict`, `predict_proba`, or `decision_function`. Multioutput-multiclass classifiers are not supported.

- `X` [[array-like or dataframe] of shape (n_samples, n_features)] X is used both to generate a grid of values for the features, and to compute the averaged predictions when method is 'brute'.

- `features` [array-like of {int, str}] The feature (e.g. 0) or pair of interacting features (e.g. (0, 1)) for which the partial dependency should be computed.

- `response_method` ['auto', 'predict_proba' or 'decision_function', optional (default='auto')] Specifies whether to use `predict_proba` or `decision_function` as the target response. For regressors this parameter is ignored and the response is always the output of `predict`. By default, `predict_proba` is tried first and we revert to `decision_function` if it doesn’t exist. If method is ‘recursion’, the response is always the output of `decision_function`.

- `percentiles` [tuple of float, optional (default=(0.05, 0.95))] The lower and upper percentile used to create the extreme values for the grid. Must be in [0, 1].

- `grid_resolution` [int, optional (default=100)] The number of equally spaced points on the grid, for each target feature.

- `method` [str, optional (default='auto')] The method used to calculate the averaged predictions:
  - 'recursion' is only supported for gradient boosting estimator (namely GradientBoostingClassifier, GradientBoostingRegressor, HistGradientBoostingClassifier, HistGradientBoostingRegressor) but is more efficient in terms of speed. With this method, X is only used to build the grid and the partial dependences are computed using the training data. This method does not account for the init predictor of the boosting process, which may lead to incorrect values (see warning below). With this method, the target response of a classifier is always the decision function, not the predicted probabilities.
  - 'brute' is supported for any estimator, but is more computationally intensive.
• ‘auto’:
  – ‘recursion’ is used for GradientBoostingClassifier
    and GradientBoostingRegressor if init=None,
    and for HistGradientBoostingClassifier and
    HistGradientBoostingRegressor.
  – ‘brute’ is used for all other estimators.

Returns

averaged_predictions  [ndarray, shape (n_outputs, len(values[0]), len(values[1]), ...)] The predictions for all the points in the grid, averaged over all samples in X (or over the training data if method is ‘recursion’). n_outputs corresponds to the number of classes in a multi-class setting, or to the number of tasks for multi-output regression. For classical regression and binary classification n_outputs==1. n_values_feature_j corresponds to the size values[j].

values  [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in values. len(values) == len(features). The size of each array values[j] is either grid_resolution, or the number of unique values in X[:, j], whichever is smaller.

Warning: The ‘recursion’ method only works for gradient boosting estimators, and unlike the ‘brute’ method, it does not account for the init predictor of the boosting process. In practice this will produce the same values as ‘brute’ up to a constant offset in the target response, provided that init is a constant estimator (which is the default). However, as soon as init is not a constant estimator, the partial dependence values are incorrect for ‘recursion’. This is not relevant for HistGradientBoostingClassifier and HistGradientBoostingRegressor, which do not have an init parameter.

sklearn.inspection.plot_partial_dependence  Plot partial dependence

Examples

>>> X = [[0, 0, 2], [1, 0, 0]]
>>> y = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(X, y)
>>> partial_dependence(gb, features=[0], X=X, percentiles=(0, 1),
...                   grid_resolution=2)  # doctest: +SKIP
(array([[-4.52..., 4.52...]]), [array([ 0., 1.])])

Examples using sklearn.inspection.partial_dependence

• Partial Dependence Plots

7.18.2 sklearn.inspection.permutation_importance

sklearn.inspection.permutation_importance(estimator, X, y, scoring=None, n_repeats=5, n_jobs=None, random_state=None)

Permutation importance for feature evaluation [BRE].
The estimator is required to be a fitted estimator. $X$ can be the data set used to train the estimator or a hold-out set. The permutation importance of a feature is calculated as follows. First, a baseline metric, defined by `scoring`, is evaluated on a (potentially different) dataset defined by the $X$. Next, a feature column from the validation set is permuted and the metric is evaluated again. The permutation importance is defined to be the difference between the baseline metric and metric from permutating the feature column.

Read more in the User Guide.

Parameters

- **estimator** [object] An estimator that has already been fitted and is compatible with `scorer`.
- **$X$** [ndarray or DataFrame, shape (n_samples, n_features)] Data on which permutation importance will be computed.
- **$y$** [array-like or None, shape (n_samples,), or (n_samples, n_classes)] Targets for supervised or None for unsupervised.
- **scoring** [string, callable or None, default=None] Scorer to use. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator’s default scorer is used.
- **n_repeats** [int, default=5] Number of times to permute a feature.
- **n_jobs** [int or None, default=None] The number of jobs to use for the computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **random_state** [int, RandomState instance, or None, default=None] Pseudo-random number generator to control the permutations of each feature. See random_state.

Returns

- **result** [Bunch] Dictionary-like object, with attributes:
  - **importances_mean** [ndarray, shape (n_features,)] Mean of feature importance over n_repeats.
  - **importances_std** [ndarray, shape (n_features,)] Standard deviation over n_repeats.
  - **importances** [ndarray, shape (n_features, n_repeats)] Raw permutation importance scores.

7.18.3 Plotting

`inspection.PartialDependenceDisplay(...)` Partial Dependence Plot (PDP) visualization.
sklearn.inspection.PartialDependenceDisplay

class sklearn.inspection.PartialDependenceDisplay(pd_results, features, feature_names, target_idx, pdp_lim, deciles)

Partial Dependence Plot (PDP) visualization.

It is recommended to use plot_partial_dependence to create a PartialDependenceDisplay. All parameters are stored as attributes.

Read more in Advanced Plotting With Partial Dependence and the User Guide.

New in version 0.22.

Parameters

pd_results [list of (ndarray, ndarray)] Results of partial_dependence for features. Each tuple corresponds to a (averaged_predictions, grid).

features [list of (int,) or list of (int, int)] Indices of features for a given plot. A tuple of one integer will plot a partial dependence curve of one feature. A tuple of two integers will plot a two-way partial dependence curve as a contour plot.

feature_names [list of str] Feature names corresponding to the indices in features.

target_idx [int]

• In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.

• In a multioutput setting, specifies the task for which the PDPs should be computed. Ignored in binary classification or classical regression settings.

pdp_lim [dict] Global min and max average predictions, such that all plots will have the same scale and y limits. pdp_lim[1] is the global min and max for single partial dependence curves. pdp_lim[2] is the global min and max for two-way partial dependence curves.

deciles [dict] Deciles for feature indices in features.

Attributes

bounding_ax_ [matplotlib Axes or None] If ax is an axes or None, the bounding_ax_ is the axes where the grid of partial dependence plots are drawn. If ax is a list of axes or a numpy array of axes, bounding_ax_ is None.

axes_ [ndarray of matplotlib Axes] If ax is an axes or None, axes_[i, j] is the axes on the i-th row and j-th column. If ax is a list of axes, axes_[i] is the i-th item in ax. Elements that are None corresponds to a nonexisting axes in that position.

lines_ [ndarray of matplotlib Artists] If ax is an axes or None, lines_[i, j] is the partial dependence curve on the i-th row and j-th column. If ax is a list of axes, lines_[i] is the partial dependence plot corresponding to the i-th item in ax. Elements that are None corresponds to a nonexisting axes or an axes that does not include a line plot.

contours_ [ndarray of matplotlib Artists] If ax is an axes or None, contours_[i, j] is the partial dependence plot on the i-th row and j-th column. If ax is a list of axes, contours_[i] is the partial dependence plot corresponding to the i-th item in ax. Elements that are None corresponds to a nonexisting axes or an axes that does not include a contour plot.

figure_ [matplotlib Figure] Figure containing partial dependence plots.
Methods

```python
plot(self, ax=None, n_cols=3, line_kw=None, contour_kw=None)
```
Plot partial dependence plots.

```python
__init__(self, pd_results, features, feature_names, target_idx, pdp_lim, deciles)
```
Initialize self. See help(type(self)) for accurate signature.

```python
plot(self, ax=None, n_cols=3, line_kw=None, contour_kw=None)
```
Plot partial dependence plots.

**Parameters**

- **ax** [Matplotlib axes or array-like of Matplotlib axes, default=None]
  - If a single axis is passed in, it is treated as a bounding axes and a grid of partial dependence plots will be drawn within these bounds. The `n_cols` parameter controls the number of columns in the grid.
  - If an array-like of axes are passed in, the partial dependence plots will be drawn directly into these axes.
  - If None, a figure and a bounding axes is created and treated as the single axes case.

- **n_cols** [int, default=3] The maximum number of columns in the grid plot. Only active when `ax` is a single axes or None.

- **line_kw** [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.plot call. For one-way partial dependence plots.

- **contour_kw** [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.contourf call for two-way partial dependence plots.

**Returns**

- **display:** `PartialDependenceDisplay`

```python
inspection.plot_partial_dependence(...[, ...])
```

**sklearn.inspection.plot_partial_dependence**

```python
sklearn.inspection.plot_partial_dependence(estimator, X, features=None, feature_names=None, target=None, response_method='auto', n_cols=3, grid_resolution=100, percentiles=(0.05, 0.95), method='auto', n_jobs=None, verbose=0, fig=None, line_kw=None, contour_kw=None, ax=None)
```
Partial dependence plots.

The `len(features)` plots are arranged in a grid with `n_cols` columns. Two-way partial dependence plots are plotted as contour plots. The deciles of the feature values will be shown with tick marks on the x-axes for one-way plots, and on both axes for two-way plots.

**Note:** `plot_partial_dependence` does not support using the same axes with multiple calls. To plot the partial dependence for multiple estimators, please pass the axes created by the first call to the second call:
```python
>>> from sklearn.inspection import plot_partial_dependence
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.linear_model import LinearRegression

>>> X, y = make_friedman1()
>>> est = LinearRegression().fit(X, y)
>>> disp1 = plot_partial_dependence(est, X)
>>> disp2 = plot_partial_dependence(est, X,
... ax=disp1.axes_)

Read more in the User Guide.

**Parameters**

- **estimator** [BaseEstimator] A fitted estimator object implementing `predict`, `predict_proba`, or `decision_function`. Multioutput-multiclass classifiers are not supported.

- **X** [array-like or dataframe] of shape (n_samples, n_features) The data to use to build the grid of values on which the dependence will be evaluated. This is usually the training data.

- **features** [list of (int, str, pair of int, pair of str)] The target features for which to create the PDPs. If features[i] is an int or a string, a one-way PDP is created; if features[i] is a tuple, a two-way PDP is created. Each tuple must be of size 2. if any entry is a string, then it must be in `feature_names`.

- **feature_names** [array-like of shape (n_features,), dtype=str, default=None] Name of each feature; feature_names[i] holds the name of the feature with index i. By default, the name of the feature corresponds to their numerical index for NumPy array and their column name for pandas dataframe.

- **target** [int, optional (default=None)]
  - In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
  - In a multioutput setting, specifies the task for which the PDPs should be computed. Ignored in binary classification or classical regression settings.

- **response_method** [‘auto’, ‘predict_proba’ or ‘decision_function’, optional (default=’auto’)]: Specifies whether to use `predict_proba` or `decision_function` as the target response. For regressors this parameter is ignored and the response is always the output of `predict`. By default, `predict_proba` is tried first and we revert to `decision_function` if it doesn’t exist. If `method` is ‘recursion’, the response is always the output of `decision_function`.

- **n_cols** [int, optional (default=3)] The maximum number of columns in the grid plot. Only active when `ax` is a single axis or `None`.

- **grid_resolution** [int, optional (default=100)] The number of equally spaced points on the axes of the plots, for each target feature.

- **percentiles** [tuple of float, optional (default=(0.05, 0.95))] The lower and upper percentile used to create the extreme values for the PDP axes. Must be in [0, 1].

- **method** [str, optional (default=’auto’)] The method to use to calculate the partial dependence predictions:
  - ‘recursion’ is only supported for gradient boosting estimator (namely `GradientBoostingClassifier`, `GradientBoostingRegressor`, `HistGradientBoostingClassifier`, `HistGradientBoostingRegressor`) but is more efficient in terms of speed. With
this method, X is optional and is only used to build the grid and the partial dependences are computed using the training data. This method does not account for the init predictor of the boosting process, which may lead to incorrect values (see warning below. With this method, the target response of a classifier is always the decision function, not the predicted probabilities.

• ‘brute’ is supported for any estimator, but is more computationally intensive.
• ‘auto’: - ‘recursion’ is used for estimators that supports it. - ‘brute’ is used for all other estimators.

n_jobs [int, optional (default=None)] The number of CPUs to use to compute the partial dependences. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int, optional (default=0)] Verbose output during PD computations.

fig [Matplotlib figure object, optional (default=None)] A figure object onto which the plots will be drawn, after the figure has been cleared. By default, a new one is created.

Deprecated since version 0.22: fig will be removed in 0.24.

line_kw [dict, optional] Dict with keywords passed to the matplotlib.pyplot.plot call. For one-way partial dependence plots.

contour_kw [dict, optional] Dict with keywords passed to the matplotlib.pyplot.contourf call. For two-way partial dependence plots.

ax [Matplotlib axes or array-like of Matplotlib axes, default=None]

• If a single axis is passed in, it is treated as a bounding axes and a grid of partial dependence plots will be drawn within these bounds. The n_cols parameter controls the number of columns in the grid.

• If an array-like of axes are passed in, the partial dependence plots will be drawn directly into these axes.

• If None, a figure and a bounding axes is created and treated as the single axes case.

New in version 0.22.

Returns

display: PartialDependenceDisplay

Warning: The ‘recursion’ method only works for gradient boosting estimators, and unlike the ‘brute’ method, it does not account for the init predictor of the boosting process. In practice this will produce the same values as ‘brute’ up to a constant offset in the target response, provided that init is a constant estimator (which is the default). However, as soon as init is not a constant estimator, the partial dependence values are incorrect for ‘recursion’. This is not relevant for HistGradientBoostingClassifier and HistGradientBoostingRegressor, which do not have an init parameter.

- Partial Dependence Plots

### 7.19 sklearn.isotonic: Isotonic regression

**User guide:** See the Isotonic regression section for further details.

```python
isotonic.IsotonicRegression([y_min,
   y_max, ...])
```

#### 7.19.1 sklearn.isotonic.IsotonicRegression

**class sklearn.isotonic.IsotonicRegression**(y_min=None, y_max=None, increasing=True, out_of_bounds='nan')

Isotonic regression model.

The isotonic regression optimization problem is defined by:

\[
\text{min} \sum w_i (y[i] - y_[i])^2 \\
\text{subject to } y_[i] \leq y_[j] \text{ whenever } X[i] \leq X[j] \\
\text{and } \min(y_) = y_min, \max(y_) = y_max
\]

where:

- \(y[i]\) are inputs (real numbers)
- \(y_[i]\) are fitted
- \(X\) specifies the order. If \(X\) is non-decreasing then \(y_\) is non-decreasing.
- \(w[i]\) are optional strictly positive weights (default to 1.0)

Read more in the **User Guide**.

New in version 0.13.

**Parameters**

- `y_min` [optional, default: None] If not None, set the lowest value of the fit to `y_min`.
- `y_max` [optional, default: None] If not None, set the highest value of the fit to `y_max`. 
increasing [boolean or string, optional, default: True] If boolean, whether or not to fit the isotonic regression with y increasing or decreasing. The string value “auto” determines whether y should increase or decrease based on the Spearman correlation estimate’s sign.

out_of_bounds [string, optional, default: “nan”] The out_of_bounds parameter handles how x-values outside of the training domain are handled. When set to “nan”, predicted y-values will be NaN. When set to “clip”, predicted y-values will be set to the value corresponding to the nearest train interval endpoint. When set to “raise”, allow interp1d to throw ValueError.

Attributes

X_min_ [float] Minimum value of input array X_ for left bound.
X_max_ [float] Maximum value of input array X_ for right bound.
f_ [function] The stepwise interpolating function that covers the input domain X.

Notes

Ties are broken using the secondary method from Leeuw, 1977.

References

Isotone Optimization in R : Pool-Adjacent-Violators Algorithm (PAVA) and Active Set Methods Leeuw, Hornik, Mair Journal of Statistical Software 2009
Correctness of Kruskal’s algorithms for monotone regression with ties Leeuw, Psychometrica, 1977

Examples

```python
>>> from sklearn.datasets import make_regression
>>> from sklearn.isotonic import IsotonicRegression
>>> X, y = make_regression(n_samples=10, n_features=1, random_state=41)
>>> iso_reg = IsotonicRegression().fit(X.flatten(), y)
>>> iso_reg.predict([.1, .2])
array([1.8628..., 3.7256...])
```

Methods

- `fit(self, X, y[, sample_weight])` Fit the model using X, y as training data.
- `fit_transform(self, X[, y])` Fit to data, then transform it.
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, T)` Predict new data by linear interpolation.
- `score(self, X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, T)` Transform new data by linear interpolation.
__init__ (self, y_min=None, y_max=None, increasing=True, out_of_bounds='nan')
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y, sample_weight=None)
Fit the model using X, y as training data.

Parameters

X [array-like of shape (n_samples,)] Training data.
y [array-like of shape (n_samples,)] Training target.
sample_weight [array-like of shape (n_samples,), default=None] Weights. If set to None, all weights will be set to 1 (equal weights).

Returns

Notes

X is stored for future use, as transform needs X to interpolate new input data.

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, T)
Predict new data by linear interpolation.

Parameters

T [array-like of shape (n_samples,)] Data to transform.

Returns

T_ [array, shape=(n_samples,)] Transformed data.
**score** *(self, X, y, sample_weight=None)*

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] R^2 of self.predict(X) wrt. y.

**Notes**

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, T)*

Transform new data by linear interpolation

**Parameters**

- **T** [array-like of shape (n_samples,)] Data to transform.

**Returns**

- **T_** [array, shape=(n_samples,)] The transformed data

**Examples using sklearn.isotonic.IsotonicRegression**

- *Isotonic Regression*
### 7.19.2 sklearn.isotonic.check_increasing

**sklearn.isotonic.check_increasing** (x, y)

Determine whether y is monotonically correlated with x.

**Parameters**

- x [array-like of shape (n_samples,)] Training data.
- y [array-like of shape (n_samples,)] Training target.

**Returns**

- *increasing_bool* [boolean] Whether the relationship is increasing or decreasing.

**Notes**

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.

**References**

### 7.19.3 sklearn.isotonic.isotonic_regression

**sklearn.isotonic.isotonic_regression** (y, sample_weight=None, y_min=None, y_max=None, increasing=True)

Solve the isotonic regression model:

\[
\min \sum w[i] (y[i] - y[i])^2
\]

subject to \(y_{\text{min}} = y[1] \leq y[2] \ldots \leq y[n] = y_{\text{max}}\)

**where:**

- \(y[i]\) are inputs (real numbers)
- \(y[i]\) are fitted
- \(w[i]\) are optional strictly positive weights (default to 1.0)

Read more in the [User Guide](http://scikit-learn.org/stable/user_guide/).

**Parameters**

- y [iterable of floats] The data.
sample_weight  [iterable of floats, optional, default: None] Weights on each point of the regression. If None, weight is set to 1 (equal weights).

y_min  [optional, default: None] If not None, set the lowest value of the fit to y_min.

y_max  [optional, default: None] If not None, set the highest value of the fit to y_max.

increasing  [boolean, optional, default: True] Whether to compute y_ is increasing (if set to True) or decreasing (if set to False)

Returns

y_  [list of floats] Isotonic fit of y.

7.20 sklearn.kernel_approximation Kernel Approximation

The sklearn.kernel_approximation module implements several approximate kernel feature maps base on Fourier transforms.

User guide: See the Kernel Approximation section for further details.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kernel_approximation.AdditiveChi2Sampler(...)</td>
<td>Approximate feature map for additive chi2 kernel.</td>
</tr>
<tr>
<td>kernel_approximation.Nystroem(kernel, ...)</td>
<td>Approximate a kernel map using a subset of the training data.</td>
</tr>
<tr>
<td>kernel_approximation.RBFSampler(gamma, ...)</td>
<td>Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.</td>
</tr>
<tr>
<td>kernel_approximation.SkewedChi2Sampler(...)</td>
<td>Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.</td>
</tr>
</tbody>
</table>

7.20.1 sklearn.kernel_approximation.AdditiveChi2Sampler

class sklearn.kernel_approximation.AdditiveChi2Sampler(sample_steps=2, sample_interval=None)

Approximate feature map for additive chi2 kernel.

Uses sampling the fourier transform of the kernel characteristic at regular intervals.

Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into 2*sample_steps+1 features, where sample_steps is a parameter of the method. Typical values of sample_steps include 1, 2 and 3.

Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable.

Read more in the User Guide.

Parameters

sample_steps  [int, optional] Gives the number of (complex) sampling points.
**sample_interval** [float, optional] Sampling interval. Must be specified when sample_steps not in {1,2,3}.

**Attributes**

**sample_interval_** [float] Stored sampling interval. Specified as a parameter if sample_steps not in {1,2,3}.

**See also:**

*SkewedChi2Sampler* A Fourier-approximation to a non-additive variant of the chi squared kernel.

*sklearn.metrics.pairwise.chi2_kernel* The exact chi squared kernel.

*sklearn.metrics.pairwise.additive_chi2_kernel* The exact additive chi squared kernel.

**Notes**

This estimator approximates a slightly different version of the additive chi squared kernel than `metric.additive_ch2` computes.

**References**

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.kernel_approximation import AdditiveChi2Sampler

>>> X, y = load_digits(return_X_y=True)
>>> chi2sampler = AdditiveChi2Sampler(sample_steps=2)
>>> X_transformed = chi2sampler.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=5, random_state=0, tol=1e-3)
>>> clf.fit(X_transformed, y)
SGDClassifier(max_iter=5, random_state=0)
>>> clf.score(X_transformed, y)
0.9499...
```

<tbody>
<tr>
<td><code>__init__</code></td>
<td>Initialize self. See help(type(self)) for accurate signature.</td>
</tr>
</tbody>
</table>
Parameters

X  [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number
    of samples and n_features is the number of features.

Returns

self  [object] Returns the transformer.

fit_transform(self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X  [numpy array of shape [n_samples, n_features]] Training set.

y  [numpy array of shape [n_samples]] Target values.

**fit_params  [dict] Additional fit parameters.

Returns

X_new  [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained
      subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

transform(self, X)
Apply approximate feature map to X.

Parameters

X  [(array-like, sparse matrix) of shape (n_samples, n_features)]

Returns

X_new  [(array, sparse matrix), shape = (n_samples, n_features * (2*sample_steps + 1))]  
Whether the return value is an array of sparse matrix depends on the type of the input X.
Approximate a kernel map using a subset of the training data.
Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the User Guide.

New in version 0.13.

Parameters

- **kernel** [string or callable, default=”rbf”] Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.
- **gamma** [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.
- **coef0** [float, default=None] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.
- **degree** [float, default=None] Degree of the polynomial kernel. Ignored by other kernels.
- **kernel_params** [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.
- **n_components** [int] Number of features to construct. How many data points will be used to construct the mapping.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- **components_** [array, shape (n_components, n_features)] Subset of training points used to construct the feature map.
- **component_indices_** [array, shape (n_components)] Indices of components_ in the training set.
- **normalization_** [array, shape (n_components, n_components)] Normalization matrix needed for embedding. Square root of the kernel matrix on components_.

See also:

- **RBFSampler** An approximation to the RBF kernel using random Fourier features.
- **sklearn.metrics.pairwise.kernel_metrics** List of built-in kernels.

References

- Williams, C.K.I. and Seeger, M. “Using the Nystroem method to speed up kernel machines”, Advances in neural information processing systems 2001

Examples

```python
>>> from sklearn import datasets, svm
>>> from sklearn.kernel_approximation import Nystroem
>>> X, y = datasets.load_digits(n_class=9, return_X_y=True)
>>> data = X / 16.
>>> clf = svm.LinearSVC()
>>> feature_map_nystroem = Nystroem(gamma=0.2,
...                                 random_state=1,
...                                 n_components=300)
>>> data_transformed = feature_map_nystroem.fit_transform(data)
>>> clf.fit(data_transformed, y)
LinearSVC()
>>> clf.score(data_transformed, y)
0.9987...
```

Methods

- `fit(self, X[, y])` Fit estimator to data.
- `fit_transform(self, X[, y])` Fit to data, then transform it.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, \*
params) Set the parameters of this estimator.
- `transform(self, X)` Apply feature map to X.

```python
__init__(self, kernel='rbf', gamma=None, coef0=None, degree=None, kernel_params=None,
         n_components=100, random_state=None)
Initialize self. See help(type(self)) for accurate signature.
```

- `fit (self, X, y=None)` Fit estimator to data.
  
  Samples a subset of training points, computes kernel on these and computes normalization matrix.

  **Parameters**
  
  `X` [array-like of shape (n_samples, n_features)] Training data.

- `fit_transform (self, X, y=None, **fit_params)` Fit to data, then transform it.
  
  Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

  **Parameters**
  
  `X` [numpy array of shape [n_samples, n_features]] Training set.
  
  `y` [numpy array of shape [n_samples]] Target values.

  **Returns**
  
  `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.
**get_params**(self, deep=True)
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params**(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

**transform**(self, X)
Apply feature map to X.

Computes an approximate feature map using the kernel between some training points and X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Data to transform.

Returns

- **X_transformed** [array, shape=(n_samples, n_components)] Transformed data.

**Examples using sklearn.kernel_approximation.Nystroem**

- Explicit feature map approximation for RBF kernels

### 7.20.3 sklearn.kernel_approximation.RBFSampler

**class** sklearn.kernel_approximation.RBFSampler**(gamma=1.0, n_components=100, random_state=None)**

Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.

It implements a variant of Random Kitchen Sinks.[1]

Read more in the User Guide.

Parameters

- **gamma** [float] Parameter of RBF kernel: \( \exp(-\gamma x^2) \)
- **n_components** [int] Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.
**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Notes**

See “Random Features for Large-Scale Kernel Machines” by A. Rahimi and Benjamin Recht.

**Examples**

```python
>>> from sklearn.kernel_approximation import RBFSampler
>>> from sklearn.linear_model import SGDClassifier

>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> rbf_feature = RBFSampler(gamma=1, random_state=1)
>>> X_features = rbf_feature.fit_transform(X)
>>> clf = SGDClassifier(max_iter=5, tol=1e-3)
>>> clf.fit(X_features, y)
>>> clf.score(X_features, y)
1.0
```

**Methods**

- `fit(self, X[, y])` Fit the model with X.
- `fit_transform(self, X[, y])` Fit to data, then transform it.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Apply the approximate feature map to X.

**__init__** (self, gamma=1.0, n_components=100, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

**fit** (self, X, y=None)
Fit the model with X.

Samples random projection according to n_features.

**Parameters**

- **X** [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

**Returns**

- **self** [object] Returns the transformer.

**fit_transform** (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
Parameters

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (self, deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

**transform** (self, X)

Apply the approximate feature map to X.

Parameters

- **X** [[array-like, sparse matrix], shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features.

Returns

- **X_new** [array-like, shape (n_samples, n_components)]

Examples using sklearn.kernel_approximation.RBFSampler

- Explicit feature map approximation for RBF kernels

7.20.4 sklearn.kernel_approximation.SkewedChi2Sampler

**class** sklearn.kernel_approximation.SkewedChi2Sampler (skewedness=1.0, n_components=100, random_state=None)

Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.

Read more in the User Guide.
Parameters

**skewedness** [float] “skewedness” parameter of the kernel. Needs to be cross-validated.

**n_components** [int] number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

See also:

**AdditiveChi2Sampler** A different approach for approximating an additive variant of the chi squared kernel.

**sklearn.metrics.pairwise.chi2_kernel** The exact chi squared kernel.

References

See “Random Fourier Approximations for Skewed Multiplicative Histogram Kernels” by Fuxin Li, Catalin Ionescu and Cristian Sminchisescu.

Examples

```python
>>> from sklearn.kernel_approximation import SkewedChi2Sampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> chi2_feature = SkewedChi2Sampler(skewedness=.01,
...                                  n_components=10,
...                                  random_state=0)
>>> X_features = chi2_feature.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=10)
>>> clf.score(X_features, y)
1.0
```

Methods

```python
fit(self, X[, y])
fit_transform(self, X[, y])
get_params(self[, deep])
set_params(self,**params)
transform(self, X)
```

```python
__init__(self, skewedness=1.0, n_components=100, random_state=None)
Initialize self. See help(type(self)) for accurate signature.
```

```python
fit(self, X, y=None)
Fit the model with X.
```
Samples random projection according to n_features.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the transformer.

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Apply the approximate feature map to X.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features. All values of X must be strictly greater than “-skewedness”.

Returns

X_new [array-like, shape (n_samples, n_components)]
**7.21 sklearn.kernel_ridge Kernel Ridge Regression**

Module `sklearn.kernel_ridge` implements kernel ridge regression.

**User guide:** See the Kernel ridge regression section for further details.

```python
kernel_ridge.KernelRidge([alpha, kernel, ...])
```

### 7.21.1 sklearn.kernel_ridge.KernelRidge

**class sklearn.kernel_ridge.KernelRidge (alpha=1, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None)**

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for epsilon > 0, at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the *User Guide*.

**Parameters**

- `alpha` [[float, array-like], shape = [n_targets]] Small positive values of alpha improve the conditioning of the problem and reduce the variance of the estimates. Alpha corresponds to \((2*C)^{-1}\) in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

- `kernel` [string or callable, default="linear"] Kernel mapping used internally. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number. Set to “precomputed” in order to pass a precomputed kernel matrix to the estimator methods instead of samples.

- `gamma` [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

- `degree` [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

- `coef0` [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

- `kernel_params` [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

**Attributes**

- `dual_coef_` [array, shape = [n_samples] or [n_samples, n_targets]] Representation of weight vector(s) in kernel space
X_fit_ {{[array-like, sparse matrix] of shape (n_samples, n_features)]} Training data, which is also required for prediction. If kernel == “precomputed” this is instead the precomputed training matrix, shape = [n_samples, n_samples].

See also:

sklearn.linear_model.Ridge Linear ridge regression.
sklearn.svm.SVR Support Vector Regression implemented using libsvm.

References

Examples

```python
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0)
```

Methods

- `fit(self, X[, y, sample_weight])` Fit Kernel Ridge regression model
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, X)` Predict using the kernel ridge model
- `score(self, X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)` Set the parameters of this estimator.

```python
__init__(self, alpha=1, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit(self, X, y=None, sample_weight=None)
```

Fit Kernel Ridge regression model

Parameters

- **X** {{[array-like, sparse matrix] of shape (n_samples, n_features)]} Training data. If kernel == “precomputed” this is instead a precomputed kernel matrix, shape = [n_samples, n_samples].
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values
- **sample_weight** [float or array-like of shape [n_samples]] Individual weights for each sample, ignored if None is passed.

Returns
get_params (self, deep=True)

Get parameters for this estimator.

Parameters

  deep [bool, default=True] If True, will return the parameters for this estimator and contained
  subobjects that are estimators.

Returns

  params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)

Predict using the kernel ridge model

Parameters

  X [array-like, sparse matrix] of shape (n_samples, n_features) Samples. If kernel
  == “precomputed” this is instead a precomputed kernel matrix, shape = [n_samples,
  n_samples_fitted], where n_samples_fitted is the number of samples used in the fitting
  for this estimator.

Returns

  C [ndarray of shape (n_samples,) or (n_samples, n_targets)] Returns predicted values.

score (self, X, y, sample_weight=None)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares
((y_true - y_pred) ** 2).sum() and v is the total sum of squares
((y_true - y_true.mean()) ** 2).sum(). The best possible score
is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model
that always predicts the expected value of y, disregarding the input features, would get a R^2 score
of 0.0.

Parameters

  X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may
  be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,
  n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for
  the estimator.

  y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

  sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

  score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average'
from version 0.23 to keep consistent with r2_score. This will influence the score method
of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value
manually and avoid the warning, please either call r2_score directly or make a custom scorer with
make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

Examples using sklearn.kernel_ridge.KernelRidge

- Comparison of kernel ridge regression and SVR
- Comparison of kernel ridge and Gaussian process regression

### 7.22 sklearn.linear_model: Linear Models

The sklearn.linear_model module implements a variety of linear models.

**User guide:** See the Linear Models section for further details.

The following subsections are only rough guidelines: the same estimator can fall into multiple categories, depending on its parameters.

#### 7.22.1 Linear classifiers

<table>
<thead>
<tr>
<th>sklearn.linear_model.LogisticRegression([penalty, ...])</th>
<th>Logistic Regression (aka logit, MaxEnt) classifier.</th>
</tr>
</thead>
<tbody>
<tr>
<td>sklearn.linear_model.LogisticRegressionCV([Cs, ...])</td>
<td>Logistic Regression CV (aka logit, MaxEnt) classifier.</td>
</tr>
<tr>
<td>sklearn.linear_model.PassiveAggressiveClassifier([...])</td>
<td>Passive Aggressive Classifier</td>
</tr>
<tr>
<td>sklearn.linear_model.Perceptron([penalty, alpha, ...])</td>
<td>Read more in the User Guide.</td>
</tr>
<tr>
<td>sklearn.linear_model.RidgeClassifier([alpha, ...])</td>
<td>Classifier using Ridge regression.</td>
</tr>
<tr>
<td>sklearn.linear_model.RidgeClassifierCV([alphas, ...])</td>
<td>Ridge classifier with built-in cross-validation.</td>
</tr>
<tr>
<td>sklearn.linear_model.SGDClassifier([loss, penalty, ...])</td>
<td>Linear classifiers (SVM, logistic regression, a.o.) with SGD training.</td>
</tr>
</tbody>
</table>

**sklearn.linear_model.LogisticRegression**

```python
class sklearn.linear_model.LogisticRegression(penalty='l2', dual=False, tol=0.0001, C=1.0, fit_intercept=True, intercept_scaling=1, class_weight=None, random_state=None, solver='lbfgs', max_iter=100, multi_class='auto', verbose=0, warm_start=False, n_jobs=None, l1_ratio=None)
```

Logistic Regression (aka logit, MaxEnt) classifier.
In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the `multi_class` option is set to ‘ovr’, and uses the cross-entropy loss if the `multi_class` option is set to ‘multinomial’. (Currently the ‘multinomial’ option is supported only by the ‘lbfgs’, ‘sag’, ‘saga’ and ‘newton-cg’ solvers.)

This class implements regularized logistic regression using the ‘liblinear’ library, ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ solvers. Note that regularization is applied by default. It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The ‘newton-cg’, ‘sag’, and ‘lbfgs’ solvers support only L2 regularization with primal formulation, or no regularization. The ‘liblinear’ solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty. The Elastic-Net regularization is only supported by the ‘saga’ solver.

Read more in the User Guide.

Parameters

- **penalty** [‘l1’, ‘l2’, ‘elasticnet’, ‘none’], default=’l2’] Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only L2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver. If ‘none’ (not supported by the liblinear solver), no regularization is applied.
  
  New in version 0.19: l1 penalty with SAGA solver (allowing ‘multinomial’ + L1)

- **dual** [bool, default=False] Dual or primal formulation. Dual formulation is only implemented for L2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

- **tol** [float, default=1e-4] Tolerance for stopping criteria.

- **C** [float, default=1.0] Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

- **fit_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

- **intercept_scaling** [float, default=1] Useful only when the solver ‘liblinear’ is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

  Note! the synthetic feature weight is subject to L1/L2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

- **class_weight** [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

  The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

  Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

  New in version 0.17: class_weight=‘balanced’

- **random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘sag’ or ‘liblinear’.

- For small datasets, ‘liblinear’ is a good choice, whereas ‘sag’ and ‘saga’ are faster for large ones.
- For multiclass problems, only ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ handle multinomial loss; ‘liblinear’ is limited to one-versus-rest schemes.
- ‘newton-cg’, ‘lbfgs’, ‘sag’ and ‘saga’ handle L2 or no penalty
- ‘liblinear’ and ‘saga’ also handle L1 penalty
- ‘saga’ also supports ‘elasticnet’ penalty
- ‘liblinear’ does not support setting penalty=’none’

Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

Changed in version 0.22: The default solver changed from ‘liblinear’ to ‘lbfgs’ in 0.22.

**max_iter** [int, default=100] Maximum number of iterations taken for the solvers to converge.

**multi_class** [{‘auto’, ‘ovr’, ‘multinomial’}, default=’auto’] If the option chosen is ‘ovr’, then a binary problem is fit for each label. For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution, even when the data is binary. ‘multinomial’ is unavailable when solver=’liblinear’. ‘auto’ selects ‘ovr’ if the data is binary, or if solver=’liblinear’, and otherwise selects ‘multinomial’.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.

Changed in version 0.22: Default changed from ‘ovr’ to ‘auto’ in 0.22.

**verbose** [int, default=0] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver. See the Glossary.

New in version 0.17: warm_start to support lbfgs, newton-cg, sag, saga solvers.

**n_jobs** [int, default=None] Number of CPU cores used when parallelizing over classes if multi_class=’ovr’”. This parameter is ignored when the solver is set to ‘liblinear’ regardless of whether ‘multi_class’ is specified or not. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**l1_ratio** [float, default=None] The Elastic-Net mixing parameter, with 0 <= l1_ratio <= 1. Only used if penalty=’elasticnet’. Setting `l1_ratio=0 is equivalent to using penalty=’l2’, while setting l1_ratio=1 is equivalent to using penalty=’l1’. For 0 < l1_ratio <1, the penalty is a combination of L1 and L2.

**Attributes**

- **classes_** [ndarray of shape (n_classes, )] A list of class labels known to the classifier.

- **coef_** [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.
coef_ is of shape (1, n_features) when the given problem is binary. In particular, when multi_class='multinomial', coef_ corresponds to outcome 1 (True) and -coef_ corresponds to outcome 0 (False).

intercept_ [ndarray of shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision function.

If fit_intercept is set to False, the intercept is set to zero. intercept_ is of shape (1,) when the given problem is binary. In particular, when multi_class='multinomial', intercept_ corresponds to outcome 1 (True) and -intercept_ corresponds to outcome 0 (False).

n_iter_ [ndarray of shape (n_classes,) or (1, )] Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.

Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed max_iter. n_iter_ will now report at most max_iter.

See also:

SGDClassifier Incrementally trained logistic regression (when given the parameter loss="log").

LogisticRegressionCV Logistic regression with built-in cross validation.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

```
__init__(self, penalty='l2', dual=False, tol=0.0001, C=1.0, fit_intercept=True, intercept_scaling=1, class_weight=None, random_state=None, solver='lbfgs', max_iter=100, multi_class='auto', verbose=0, warm_start=False, n_jobs=None, l1_ratio=None)
```

Initialize self. See help(type(self)) for accurate signature.

**decision_function**

```
Predict confidence scores for samples.

Parameters

- X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.
```

**densify**

```
Convert coefficient matrix to dense array format.

Returns

- self Fitted estimator.
```

**fit**

```
Fit the model according to the given training data.

Parameters

- X, y, sample_weight=None
```

---

### 7.22. sklearn.linear_model: Linear Models

2001
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y  [array-like of shape (n_samples,)] Target vector relative to X.

sample_weight  [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: sample_weight support to LogisticRegression.

Returns

self  Fitted estimator.

Notes

The SAGA solver supports both float64 and float32 bit arrays.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

dep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict class labels for samples in X.

Parameters

X  [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C  [array, shape [n_samples]] Predicted class label per sample.

predict_log_proba (self, X)
Predict logarithm of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

Parameters

X  [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

Returns

T  [array-like of shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

predict_proba (self, X)
Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function, and normalize these values across all the classes.
Parameters

**X** [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

Returns

**T** [array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

**score** *(self, X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

**X** [array-like of shape (n_samples, n_features)] Test samples.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

**self** [object] Estimator instance.

**sparsify** *(self)*

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

**self** Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.
Examples using `sklearn.linear_model.LogisticRegression`

- Compact estimator representations
- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Plot classification probability
- Plot class probabilities calculated by the VotingClassifier
- Feature transformations with ensembles of trees
- Logistic function

- Digits Classification Exercise

`sklearn.linear_model.PassiveAggressiveClassifier`

```python
class sklearn.linear_model.PassiveAggressiveClassifier (C=1.0, fit_intercept=True, max_iter=1000, tol=0.001, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, shuffle=True, verbose=0, loss='hinge', n_jobs=None, random_state=None, warm_start=False, class_weight=None, average=False)
```

Passive Aggressive Classifier

Read more in the User Guide.

Parameters

- C [float] Maximum step size (regularization). Defaults to 1.0.
**fit_intercept** [bool, default=False] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

**max_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit` method.

New in version 0.19.

**tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

New in version 0.19.

**early_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for `n_iter_no_change` consecutive epochs.

New in version 0.20.

**validation_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True.

New in version 0.20.

**n_iter_no_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, optional] The verbosity level

**loss** [string, optional] The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared_hinge: equivalent to PA-II in the reference paper.

**n_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib. parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

**class_weight** [dict, {class_label: weight} or “balanced” or None, optional] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`
New in version 0.17: parameter *class_weight* to automatically weight samples.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the *coef_* attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

**Attributes**

*coef_* [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

*intercept_* [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

*n_iter_* [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

*classes_* [array of shape (n_classes,)] The unique classes labels.

*t_* [int] Number of weight updates performed during training. Same as (n_iter_* * n_samples).

__init__(self, C=1.0, fit_intercept=True, max_iter=1000, tol=0.001, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, shuffle=True, verbose=0, loss='hinge', n_jobs=None, random_state=None, warm_start=False, class_weight=None, average=False)

Initialize self. See help(type(self)) for accurate signature.

decision_function(self, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

- X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify(self)

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

- self Fitted estimator.

fit (self, X, y, coef_init=None, intercept_init=None)

Fit linear model with Passive Aggressive algorithm.

Parameters

- X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data
- y [numpy array of shape [n_samples]] Target values
- coef_init [array, shape = [n_classes,n_features]] The initial coefficients to warm-start the optimization.
- intercept_init [array, shape = [n_classes]] The initial intercept to warm-start the optimization.

Returns

- self [returns an instance of self.]
get_params (self, deep=True)
Get parameters for this estimator.

Parameters

 deep [bool, default=True] If True, will return the parameters for this estimator and contained
        subobjects that are estimators.

Returns

 params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y, classes=None)
Fit linear model with Passive Aggressive algorithm.

Parameters

 X [[array-like, sparse matrix] of shape (n_samples, n_features)] Subset of the training data
 y [numpy array of shape [n_samples]] Subset of the target values
 classes [array, shape = [n_classes]] Classes across all calls to partial_fit. Can be obtained
        by via np.unique(y_all), where y_all is the target vector of the entire dataset. This
        argument is required for the first call to partial_fit and can be omitted in the subsequent
        calls. Note that y doesn’t need to contain all labels in classes.

Returns

 self [returns an instance of self.]

predict (self, X)
Predict class labels for samples in X.

Parameters

 X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

 C [array, shape [n_samples]] Predicted class label per sample.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

 X [array-like of shape (n_samples, n_features)] Test samples.
 y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
 sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

 score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **kwargs)
Set and validate the parameters of estimator.

Parameters

 **kwargs [dict] Estimator parameters.

Returns
self [object] Estimator instance.

sparsify (self)
Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.PassiveAggressiveClassifier

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

sklearn.linear_model.Perceptron

class sklearn.linear_model.Perceptron (penalty=None, alpha=0.0001, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, eta0=1.0, n_jobs=None, random_state=0, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, class_weight=None, warm_start=False)

Read more in the User Guide.

Parameters

penalty ['l2', 'l1', 'elasticnet'], default=None] The penalty (aka regularization term) to be used.

alpha [float, default=0.0001] Constant that multiplies the regularization term if regularization is used.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

New in version 0.19.
tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when
(loss > previous_loss - tol).

    New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each
epoch.

verbose [int, default=0] The verbosity level

eta0 [double, default=1] Constant by which the updates are multiplied.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus
All, for multi-class problems) computation. None means 1 unless in a joblib.
parallel_backend context. -1 means using all processors. See Glossary for more
details.

random_state [int, RandomState instance, default=None] The seed of the pseudo random num-
ber generator to use when shuffling the data. If int, random_state is the seed used by the
random number generator; If RandomState instance, random_state is the random number
generator; If None, the random number generator is the RandomState instance used by np.
random.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when
validation. score is not improving. If set to True, it will automatically set aside a stratified
fraction of training data as validation and terminate training when validation score is not
improving by at least tol for n_iter_no_change consecutive epochs.

    New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation
set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

    New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before
early stopping.

    New in version 0.20.

class_weight [dict, {class_label: weight} or “balanced”, default=None] Preset for the
class_weight fit parameter.

    Weights associated with classes. If not given, all classes are supposed to have weight one.

    The “balanced” mode uses the values of y to automatically adjust weights inversely pro-
portional to class frequencies in the input data as n_samples / (n_classes * np.
bincount(y))

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to
fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Attributes

coeff_ [ndarray of shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights
assigned to the features.

intercept_ [ndarray of shape = [1] if n_classes == 2 else [n_classes]] Constants in decision
function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits,
it is the maximum over every binary fit.

classes_ [ndarray of shape (n_classes,)] The unique classes labels.
t_ [int] Number of weight updates performed during training. Same as \((n_{\text{iter}} \times n_{\text{samples}})\).

See also:

SGDClassifier

Notes

Perceptron is a classification algorithm which shares the same underlying implementation with SGDClassifier. In fact, Perceptron() is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

__init__ (self, penalty=None, alpha=0.0001, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, eta0=1.0, n_jobs=None, random_state=0, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, class_weight=None, warm_start=False)

Initialize self. See help(type(self)) for accurate signature.

decision_function (self, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.
Parameters

X  [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)  Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify(self)
Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self  Fitted estimator.

fit(self, X, y, coef_init=None, intercept_init=None, sample_weight=None)
Fit linear model with Stochastic Gradient Descent.

Parameters

X  [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data.
y  [ndarray of shape (n_samples,)] Target values.
coef_init  [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.
intercept_init  [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.
sample_weight  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns

self:  Returns an instance of self.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(self, X, y, classes=None, sample_weight=None)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X  [{array-like, sparse matrix}, shape (n_samples, n_features)] Subset of the training data.
y [ndarray of shape (n_samples,)] Subset of the target values.

classes [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit.
    Can be obtained by via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self : Returns an instance of self.

predict (self, X)
    Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score (self, X, y, sample_weight=None)
    Return the mean accuracy on the given test data and labels.
    In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **kwargs)
    Set and validate the parameters of estimator.

Parameters

**kwargs [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify (self)
    Convert coefficient matrix to sparse format.
    Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.
    The intercept_ member is not converted.

Returns

self [object] Fitted estimator.
Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.Perceptron`

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

`sklearn.linear_model.RidgeClassifier`

class sklearn.linear_model.RidgeClassifier

Classifier using Ridge regression.

This classifier first converts the target values into {-1, 1} and then treats the problem as a regression task (multi-output regression in the multiclass case).

Read more in the User Guide.

Parameters

- **alpha** [float, default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $C^{-1}$ in other linear models such as LogisticRegression or LinearSVC.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

- **normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling fit on an estimator with normalize=False.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

- **max_iter** [int, default=None] Maximum number of iterations for conjugate gradient solver. The default value is determined by scipy.sparse.linalg.

- **tol** [float, default=1e-3] Precision of the solution.

- **class_weight** [dict or ‘balanced’, default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

  The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`. 

- ‘auto’ chooses the solver automatically based on the type of data.
- ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).
- ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
- ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.
New in version 0.19: SAGA solver.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘sag’.

**Attributes**

**coef_** [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

coef_ is of shape (1, n_features) when the given problem is binary.

**intercept_** [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

**n_iter_** [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

**classes_** [ndarray of shape (n_classes,)] The classes labels.

**See also:**

*Ridge* Ridge regression.

*RidgeClassifierCV* Ridge classifier with built-in cross validation.

**Notes**

For multi-class classification, n_class classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.
Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import RidgeClassifier

>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = RidgeClassifier().fit(X, y)
>>> clf.score(X, y)
0.9595...
```

Methods

decision_function(self, X) Predict confidence scores for samples.

fit(self, X, y[, sample_weight]) Fit Ridge classifier model.

get_params(self[, deep]) Get parameters for this estimator.

predict(self, X) Predict class labels for samples in X.

score(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.

set_params(self, **params) Set the parameters of this estimator.

__init__(self, alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, class_weight=None, solver='auto', random_state=None) Initialize self. See help(type(self)) for accurate signature.

decision_function (self, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit (self, X, y, sample_weight=None)

Fit Ridge classifier model.

Parameters

X [{ndarray, sparse matrix] of shape (n_samples, n_features)] Training data.

y [ndarray of shape (n_samples,)] Target values.

sample_weight [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

New in version 0.17: sample_weight support to Classifier.

Returns

self [object] Instance of the estimator.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.linear_model.RidgeClassifier

- Classification of text documents using sparse features
sklearn.linear_model.SGDClassifier

**class sklearn.linear_model.SGDClassifier**

(loss='hinge', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, n_jobs=None, random_state=None, learning_rate='optimal', eta0=0.0, power_t=0.5, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, class_weight=None, warm_start=False, average=False)

Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning, see the partial_fit method. For best results using the default learning rate schedule, the data should have zero mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

Read more in the User Guide.

**Parameters**

- **loss** [str, default='hinge'] The loss function to be used. Defaults to ‘hinge’, which gives a linear SVM.
  
  
The ‘log’ loss gives logistic regression, a probabilistic classifier. ‘modified_huber’ is another smooth loss that brings tolerance to outliers as well as probability estimates. ‘squared_hinge’ is like hinge but is quadratically penalized. ‘perceptron’ is the linear loss used by the perceptron algorithm. The other losses are designed for regression but can be useful in classification as well; see SGDRegressor for a description.

- **penalty** [‘l2’, ‘l1’, ‘elasticnet’], default=’l2’ The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

- **alpha** [float, default=0.0001] Constant that multiplies the regularization term. Defaults to 0.0001. Also used to compute learning_rate when set to ‘optimal’.

- **l1_ratio** [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Defaults to 0.15.

- **fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

- **max_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.
New in version 0.19.

tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when
(loss > best_loss - tol) for n_iter_no_change consecutive epochs.

New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each
epoch.

verbose [int, default=0] The verbosity level.

epsilon [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if loss is
'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'. For 'huber', determines
the threshold at which it becomes less important to get the prediction exactly right. For
epsilon-insensitive, any differences between the current prediction and the correct label are
ignored if they are less than this threshold.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus
All, for multi-class problems) computation. None means 1 unless in a joblib.
parallel_backend context. -1 means using all processors. See Glossary for more
details.

random_state [int, RandomState instance, default=None] The seed of the pseudo random num-
ber generator to use when shuffling the data. If int, random_state is the seed used by the
random number generator; If RandomState instance, random_state is the random number
generator; If None, the random number generator is the RandomState instance used by np.
random.

learning_rate [str, default='optimal'] The learning rate schedule:

  ‘constant’ : eta = eta0
  ‘optimal’ : [default] eta = 1.0 / (alpha * (t + t0)) where t0 is chosen by a heuristic proposed
  by Leon Bottou.
  ‘invscaling’ : eta = eta0 / pow(t, power_t)
  ‘adaptive’ : eta = eta0, as long as the training keeps decreasing. Each time
  n_iter_no_change consecutive epochs fail to decrease the training loss by tol or fail to
  increase validation score by tol if early_stopping is True, the current learning rate is di-
  vided by 5.

eta0 [double, default=0.0] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’
schedules. The default value is 0.0 as eta0 is not used by the default schedule ‘optimal’.

power_t [double, default=0.5] The exponent for inverse scaling learning rate [default 0.5].

early_stopping [bool, default=False] Whether to use early stopping to terminate training when
validation score is not improving. If set to True, it will automatically set aside a stratified
fraction of training data as validation and terminate training when validation score is not
improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation
set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before
early stopping.

New in version 0.20.
class_weight  [dict, {class_label: weight} or “balanced”, default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

warm_start  [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling fit resets this counter, while partial_fit will result in increasing the existing counter.

average  [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

Attributes

coef_  [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features.

intercept_  [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

n_iter_  [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

loss_function_  [concrete LossFunction]

classes_  [array of shape (n_classes,)]

t_  [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

See also:

sklearn.svm.LinearSVC  Linear support vector classification.

LogisticRegression  Logistic regression.

Perceptron  Inherits from SGDClassifier. Perceptron() is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

Examples

```python
>>> import numpy as np
>>> from sklearn import linear_model
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> Y = np.array([-1, -1, 1, 1])
>>> clf = linear_model.SGDClassifier(max_iter=1000, tol=1e-3)
>>> clf.fit(X, Y)
SGDClassifier()
```
>>> print(clf.predict([[-0.8, -1]]))
[1]

Methods

**decision_function**(self, X)
Predict confidence scores for samples.

**densify**(self)
Convert coefficient matrix to dense array format.

**fit**(self, X, y, [coef_init, intercept_init, ...])
Fit linear model with Stochastic Gradient Descent.

**get_params**(self[, deep])
Get parameters for this estimator.

**partial_fit**(self, X, y, [classes, sample_weight])
Perform one epoch of stochastic gradient descent on given samples.

**predict**(self, X)
Predict class labels for samples in X.

**score**(self, X, y[, sample_weight])
Return the mean accuracy on the given test data and labels.

**set_params**(self, **kwargs)
Set and validate the parameters of estimator.

**sparsify**(self)
Convert coefficient matrix to sparse format.

__init__**(self, loss='hinge', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, n_jobs=None, random_state=None, learning_rate='optimal', eta0=0.0, power_t=0.5, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, class_weight=None, warm_start=False, average=False)
Initialize self. See help(type(self)) for accurate signature.

decision_function**(self, X)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

X  [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify**(self)
Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

self  Fitted estimator.

fit  (self, X, y, coef_init=None, intercept_init=None, sample_weight=None)
Fit linear model with Stochastic Gradient Descent.

**Parameters**

X  [[array-like, sparse matrix], shape (n_samples, n_features)] Training data.

y  [ndarray of shape (n_samples,)] Target values.
coef_init [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.

intercept_init [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns

self : Returns an instance of self.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y, classes=None, sample_weight=None)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of the training data.

y [ndarray of shape (n_samples,)] Subset of the target values.

classes [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self : Returns an instance of self.

predict (self, X)
Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

property predict_log_proba
Log of probability estimates.

This method is only available for log loss and modified Huber loss.
When loss="modified_huber", probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See predict_proba for details.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Input data for prediction.

Returns

T [array-like, shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

**property predict_proba**

Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for loss="modified_huber" are given by (clip(decision_function(X), -1, 1) + 1) / 2. For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with sklearn.calibration.CalibratedClassifierCV instead.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Input data for prediction.

Returns

ndarray of shape (n_samples, n_classes) Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

**References**

The justification for the formula in the loss="modified_huber" case is in the appendix B in: http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf

**score**(self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(self, **kwargs)

Set and validate the parameters of estimator.

Parameters
**kwargs  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

sparsify(self)
Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self  Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

sklearn.linear_model.LinearRegression

class sklearn.linear_model.LinearRegression(fit_intercept=True, normalize=False, copy_X=True, n_jobs=None)

Ordinary least squares Linear Regression.

LinearRegression fits a linear model with coefficients w = (w1, ..., wp) to minimize the residual sum of squares between the observed targets in the dataset, and the targets predicted by the linear approximation.

Parameters

fit_intercept  [bool, optional, default True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize  [bool, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use
sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

copy_X  [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

n_jobs  [int or None, optional (default=None)] The number of jobs to use for the computation. This will only provide speedup for n_targets > 1 and sufficient large problems. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

coeff_  [array of shape (n_features, ) or (n_targets, n_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n_targets, n_features), while if only one target is passed, this is a 1D array of length n_features.

rank_  [int] Rank of matrix X. Only available when X is dense.

singular_  [array of shape (min(X, y),)] Singular values of X. Only available when X is dense.

intercept_  [float or array of shape of (n_targets,)] Independent term in the linear model. Set to 0.0 if fit_intercept = False.

See also:

sklearn.linear_model.Ridge Ridge regression addresses some of the problems of Ordinary Least Squares by imposing a penalty on the size of the coefficients with l2 regularization.

sklearn.linear_model.Lasso The Lasso is a linear model that estimates sparse coefficients with l1 regularization.

sklearn.linear_model.ElasticNet Elastic-Net is a linear regression model trained with both l1 and l2 -norm regularization of the coefficients.

Notes

From the implementation point of view, this is just plain Ordinary Least Squares (scipy.linalg.lstsq) wrapped as a predictor object.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> X = np.array([[1, 1], [1, 2], [2, 2], [2, 3]])
>>> # y = 1 * x_0 + 2 * x_1 + 3
>>> y = np.dot(X, np.array([1, 2])) + 3
>>> reg = LinearRegression().fit(X, y)
>>> reg.score(X, y)
1.0
>>> reg.coef_
array([1., 2.])
>>> reg.intercept_
3.0000...
>>> reg.predict(np.array([[3, 5]]))
array([16.])
```
Methods

<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

```python
__init__(self, fit_intercept=True, normalize=False, copy_X=True, n_jobs=None)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y, sample_weight=None)
```

Fit linear model.

**Parameters**

- X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data
- y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X's dtype if necessary
- sample_weight [array-like of shape (n_samples,), default=None] Individual weights for each sample

New in version 0.17: parameter sample_weight support to LinearRegression.

**Returns**

- self [returns an instance of self.]

```python
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [mapping of string to any] Parameter names mapped to their values.

```python
predict (self, X)
```

Predict using the linear model.

**Parameters**

- X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- C [array, shape (n_samples,)] Returns predicted values.

```python
score (self, X, y, sample_weight=None)
```

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,), default=None] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.linear_model.LinearRegression

• Isotonic Regression
• Face completion with a multi-output estimators
• Plot individual and voting regression predictions
• Ordinary Least Squares and Ridge Regression Variance
• Logistic function
• Linear Regression Example
• Robust linear model estimation using RANSAC
• Sparsity Example: Fitting only features 1 and 2
• Theil-Sen Regression
• Robust linear estimator fitting
• Automatic Relevance Determination Regression (ARD)
• Bayesian Ridge Regression
• Plotting Cross-Validated Predictions
• Underfitting vs. Overfitting
• Using KBinsDiscretizer to discretize continuous features

sklearn.linear_model.Ridge

class sklearn.linear_model.Ridge(alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, solver='auto', random_state=None)

Linear least squares with l2 regularization.

Minimizes the objective function:

\[ ||y - Xw||^2_2 + \alpha \cdot ||w||^2_2 \]

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape (n_samples, n_targets)).

Read more in the User Guide.

Parameters

- alpha [float, ndarray of shape (n_targets,)], default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to \( C^{-1} \) in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

- fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

- copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

- max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. For ‘sparse_cg’ and ‘lsqr’ solvers, the default value is determined by scipy.sparse.linalg. For ‘sag’ solver, the default value is 1000.

- tol [float, default=1e-3] Precision of the solution.

  - ‘auto’ chooses the solver automatically based on the type of data.
  - ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.
  - ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).
• ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
• ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale.

You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only ‘sparse_cg’ supports sparse input when fit_intercept is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘sag’.

New in version 0.17: random_state to support Stochastic Average Gradient.

Attributes

coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

n_iter_ [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

RidgeClassifier Ridge classifier

RidgeCV Ridge regression with built-in cross validation

sklearn.kernel_ridge.KernelRidge Kernel ridge regression combines ridge regression with the kernel trick

Examples

```python
>>> from sklearn.linear_model import Ridge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = Ridge(alpha=1.0)
>>> clf.fit(X, y)
Ridge()
```

Methods

7.22. sklearn.linear_model: Linear Models 2029
**fit**(self, X, y[, sample_weight])
Fit Ridge regression model.

**get_params**(self[, deep])
Get parameters for this estimator.

**predict**(self, X)
Predict using the linear model.

**score**(self, X, y[, sample_weight])
Return the coefficient of determination $R^2$ of the prediction.

**set_params**(self, **params)
Set the parameters of this estimator.

__init__(self, alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, solver='auto', random_state=None)
Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y, sample_weight=None)
Fit Ridge regression model.

Parameters

- X [{ndarray, sparse matrix} of shape (n_samples, n_features)] Training data
- y [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values
- sample_weight [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

Returns

- self [returns an instance of self.]

**get_params**(self, deep=True)
Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

**predict**(self, X)
Predict using the linear model.

Parameters

- X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- C [array, shape (n_samples,)] Returns predicted values.

**score**(self, X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $(y_{true} - y_{true.mean})^2$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

*sample_weight* [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling *score* on a regressor will use *multioutput='uniform_average'* from version 0.23 to keep consistent with *r2_score*. This will influence the *score* method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer ’r2’ uses *multioutput='uniform_average'*>).

**set_params** (*self*, **params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.linear_model.Ridge`

- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Prediction Latency
- Plot Ridge coefficients as a function of the regularization
- Ordinary Least Squares and Ridge Regression Variance
- Plot Ridge coefficients as a function of the L2 regularization
- Polynomial interpolation
- HuberRegressor vs Ridge on dataset with strong outliers

`sklearn.linear_model.SGDRegressor`

```python
class sklearn.linear_model.SGDRegressor(loss='squared_loss', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, random_state=None, learning_rate='invscaling', eta0=0.01, power_t=0.25, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, warm_start=False, average=False)
```

Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).
The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the User Guide.

Parameters

- **loss** [str, default='squared_loss'] The loss function to be used. The possible values are 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'.

  The 'squared_loss' refers to the ordinary least squares fit. 'huber' modifies 'squared_loss' to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. 'epsilon_insensitive' ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. 'squared_epsilon_insensitive' is the same but becomes squared loss past a tolerance of epsilon.

- **penalty** [{'l2', 'l1', 'elasticnet'}, default='l2'] The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

- **alpha** [float, default=0.0001] Constant that multiplies the regularization term. Also used to compute learning_rate when set to 'optimal'.

- **l1_ratio** [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1.

- **fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

- **max_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

  New in version 0.19.

- **tol** [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > best_loss - tol) for n_iter_no_change consecutive epochs.

  New in version 0.19.

- **shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

- **verbose** [int, default=0] The verbosity level.

- **epsilon** [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if loss is 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

- **random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

- **learning_rate** [string, default='invscaling'] The learning rate schedule:
‘constant’: \( \text{eta} = \text{eta0} \)

‘optimal’: \( \text{eta} = 1.0 / (\alpha \times (t + t0)) \) where \( t0 \) is chosen by a heuristic proposed by Leon Bottou.

‘invscaling’: [default] \( \text{eta} = \text{eta0} / \text{pow}(t, \text{power_t}) \)

‘adaptive’: \( \text{eta} = \text{eta0} \), as long as the training keeps decreasing. Each time \( \text{n_iter_no_change} \) consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if \( \text{early_stopping} \) is True, the current learning rate is divided by 5.

\( \text{eta0} \) [double, default=0.01] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’ schedules. The default value is 0.01.

\( \text{power_t} \) [double, default=0.25] The exponent for inverse scaling learning rate.

\( \text{early_stopping} \) [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least tol for \( \text{n_iter_no_change} \) consecutive epochs.

New in version 0.20.

\( \text{validation_fraction} \) [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if \( \text{early_stopping} \) is True.

New in version 0.20.

\( \text{n_iter_no_change} \) [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

\( \text{warm_start} \) [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when \( \text{warm_start} \) is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling fit resets this counter, while partial_fit will result in increasing the existing counter.

\( \text{average} \) [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the \( \text{coef_} \) attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So \( \text{average}=10 \) will begin averaging after seeing 10 samples.

Attributes

\( \text{coef}_{\:\text{a}} \) [ndarray of shape \((\text{n_features},)\)] Weights assigned to the features.

\( \text{intercept}_{\:\text{a}} \) [ndarray of shape \((1,)\)] The intercept term.

\( \text{average_coef}_{\:\text{a}} \) [ndarray of shape \((\text{n_features},)\)] Averaged weights assigned to the features.

\( \text{average_intercept}_{\:\text{a}} \) [ndarray of shape \((1,)\)] The averaged intercept term.

\( \text{n_iter}_{\:\text{a}} \) [int] The actual number of iterations to reach the stopping criterion.

\( \text{t}_{\:\text{a}} \) [int] Number of weight updates performed during training. Same as \((\text{n_iter}_{\:\text{a}} \times \text{n_samples})\).

See also:
**Ridge, ElasticNet, Lasso, sklearn.svm.SVR**

**Examples**

```python
>>> import numpy as np
>>> from sklearn import linear_model
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = linear_model.SGDRegressor(max_iter=1000, tol=1e-3)
>>> clf.fit(X, y)
SGDRegressor()
```

**Methods**

- `densify(self)`
  Convert coefficient matrix to dense array format.
- `fit(self, X, y[, coef_init, intercept_init, ...])`
  Fit linear model with Stochastic Gradient Descent.
- `get_params(self[, deep])`
  Get parameters for this estimator.
- `partial_fit(self, X, y[, sample_weight])`
  Perform one epoch of stochastic gradient descent on given samples.
- `predict(self, X)`
  Predict using the linear model.
- `score(self, X, y[, sample_weight])`
  Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **kwargs)`
  Set and validate the parameters of estimator.
- `sparsify(self)`
  Convert coefficient matrix to sparse format.

**__init__**(self, loss='squared_loss', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, random_state=None, learning_rate='invscaling', eta0=0.01, power_t=0.25, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, warm_start=False, average=False)

Initialize self. See help(type(self)) for accurate signature.

- `densify(self)`
  Convert coefficient matrix to dense array format.

  Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

  **Returns**

  - `self` Fitted estimator.

- `fit(self, X, y[, coef_init=None, intercept_init=None, sample_weight=None])`
  Fit linear model with Stochastic Gradient Descent.

  **Parameters**

  - `X` [[array-like, sparse matrix], shape (n_samples, n_features)] Training data
  - `y` [ndarray of shape (n_samples,)] Target values
  - `coef_init` [ndarray of shape (n_features,), default=None] The initial coefficients to warm-start the optimization.
intercept_init [ndarray of shape (1,), default=None] The initial intercept to warm-start the optimization.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns

self [returns an instance of self.]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y, sample_weight=None)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Subset of training data
y [numpy array of shape (n_samples,)] Subset of target values
sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self [returns an instance of self.]

predict (self, X)
Predict using the linear model

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)]

Returns

ndarray of shape (n_samples,) Predicted target values per element in X.

score (self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,
n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **kwargs)
Set and validate the parameters of estimator.

Parameters

**kwargs [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify (self)
Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.SGDRegressor

- Prediction Latency
### 7.22.3 Regressors with variable selection

The following estimators have built-in variable selection fitting procedures, but any estimator using a L1 or elastic-net penalty also performs variable selection: typically `SGDRegressor` or `SGDClassifier` with an appropriate penalty.

**sklearn.linear_model.ElasticNet**

```python
class sklearn.linear_model.ElasticNet(alpha=1.0, l1_ratio=0.5, fit_intercept=True, normalize=False, precompute=False, max_iter=1000, copy_X=True, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')
```

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

$$
\frac{1}{(2 \times n\_samples)} \times ||y - Xw||^2_2 \\
+ \alpha \times l1\_ratio \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||w||^2_2
$$

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

$$
a \times L1 + b \times L2
$$

where:

$$
\text{alpha} = a + b \quad \text{and} \quad l1\_ratio = a / (a + b)
$$

The parameter `l1_ratio` corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. Specifically, `l1_ratio = 1` is the lasso penalty. Currently, `l1_ratio <= 0.01` is not reliable, unless you supply your own sequence of alpha.

Read more in the *User Guide*.

**Parameters**
alpha [float, optional] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. alpha = 0 is equivalent to an ordinary least square, solved by the LinearRegression object. For numerical reasons, using alpha = 0 with the Lasso object is not advised. Given this, you should use the LinearRegression object.

l1_ratio [float] The ElasticNet mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an L2 penalty. For l1_ratio = 1 it is an L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

fit_intercept [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

normalize [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

precompute [True | False | array-like] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

max_iter [int, optional] The maximum number of iterations

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

tol [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

warm_start [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

positive [bool, optional] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘random’.

selection [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

coef_ [array, shape (n_features,) | (n_targets, n_features)] parameter vector (w in the cost function formula)

sparse_coef_ [scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)] sparse representation of the fitted coef_

intercept_ [float | array, shape (n_targets,)] independent term in decision function.

n_iter_ [array-like, shape (n_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

ElasticNetCV Elastic net model with best model selection by cross-validation.
SGDRegressor implements elastic net regression with incremental training.

SGDClassifier implements logistic regression with elastic net penalty (SGDClassifier(loss="log", penalty="elasticnet")).

Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(random_state=0)
>>> print(regr.coef_)
[18.83816048 64.55968825]
>>> print(regr.intercept_)
1.451...
>>> print(regr.predict([[0, 0]])
[1.451...]
```

Methods

- `fit(self, X, y[, check_input])` Fit model with coordinate descent.
- `get_params(self[, deep])` Get parameters for this estimator.
- `path(X, y[, l1_ratio, eps, n_alphas, ...])` Compute elastic net path with coordinate descent.
- `predict(self, X)` Predict using the linear model.
- `score(self, X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)` Set the parameters of this estimator.

__init__(self, alpha=1.0, l1_ratio=0.5, fit_intercept=True, normalize=False, precompute=False, max_iter=1000, copy_X=True, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

Initialize self. See help(type(self)) for accurate signature.

`fit(self, X, y, check_input=True)`

Fit model with coordinate descent.

Parameters

- `X` [ndarray or scipy.sparse matrix, (n_samples, n_features)] Data
- `y` [ndarray, shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X's dtype if necessary
- `check_input` [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto',
Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{samples})} \times ||y - Xw||^2_2 \\
+ \alpha \times l1_{ratio} \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1_{ratio}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{samples})} \times ||Y - XW||^Fro_2 \\
+ \alpha \times l1_{ratio} \times ||W||_21 \\
+ 0.5 \times \alpha \times (1 - l1_{ratio}) \times ||W||_{Fro}^2
\]

Where:

\[
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [[array-like], shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.
**precompute** [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’, let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy_X** [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

**coef_init** [array, shape (n_features, ) | None] The initial values of the coefficients.

**verbose** [bool or int] Amount of verbosity.

**return_n_iter** [bool] Whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

**check_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params** [kwargs] Keyword arguments passed to the coordinate descent solver.

**Returns**

**alphas** [array, shape (n_alphas,)] The alphas along the path where models are computed.

**coef** [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

**dual_gaps** [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n_iters** [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

**See also:**

*MultiTaskElasticNetCV*

*ElasticNet*

*ElasticNetCV*

**Notes**

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

**predict**(self, X)

Predict using the linear model.

**Parameters**

**X** [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

**C** [array, shape (n_samples,)] Returns predicted values.
score (self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $\sum (y_{true} - y_{pred})^2$ and $v$ is the total sum of squares $\sum (y_{true} - \text{mean}(y_{true}))^2$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict(X) wrt. $y$.

Notes

The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

property sparse_coef_

sparse representation of the fitted coef_

Examples using sklearn.linear_model.ElasticNet

- *Lasso and Elastic Net for Sparse Signals*
- *Train error vs Test error*
Least Angle Regression model a.k.a. LAR

Read more in the User Guide.

Parameters

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **verbose** [bool or int, default=False] Sets the verbosity amount
- **normalize** [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- **precompute** [bool, ‘auto’ or array-like, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.
- **n_nonzero_coefs** [int, default=500] Target number of non-zero coefficients. Use np.inf for no limit.
- **eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization. By default, np.finfo(np.float).eps is used.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **fit_path** [bool, default=True] If True the full path is stored in the coef_path_ attribute. If you compute the solution for a large problem or many targets, setting fit_path to False will lead to a speedup, especially with a small alpha.

Attributes

- **alphas_** [array-like of shape (n_alphas + 1,) | list of n_targets such arrays] Maximum of covariances (in absolute value) at each iteration. n_alphas is either n_nonzero_coefs or n_features, whichever is smaller.
- **active_** [list, length = n_alphas | list of n_targets such lists] Indices of active variables at the end of the path.
- **coef_path_** [array-like of shape (n_features, n_alphas + 1) | list of n_targets such arrays] The varying values of the coefficients along the path. It is not present if the fit_path parameter is False.
- **coef_** [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).
- **intercept_** [float or array-like of shape (n_targets,)] Independent term in decision function.
- **n_iter_** [array-like or int] The number of iterations taken by lars_path to find the grid of alphas for each target.

**__init__**

```python
__init__(self, fit_intercept=True, verbose=False, normalize=True, precompute='auto', n_nonzero_coefs=500, eps=2.220446049250313e-16, copy_X=True, fit_path=True)
```

Initialize self. See help(type(self)) for accurate signature.

**fit**

```python
fit(self, X, y[, Xy])
```

Fit the model using X, y as training data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] $Xy = \text{np.dot}(X.T, y)$ that can be precomputed. It is useful only when the Gram matrix is precomputed.

**Returns**

- **self** [object] returns an instance of self.

**get_params**

```python
get_params(self[, deep])
```

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict**

```python
predict(self, X)
```

Predict using the linear model.

**Parameters**
X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true.mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sklearn.linear_model.Lasso

class sklearn.linear_model.Lasso(alpha=1.0, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:
Technically the Lasso model is optimizing the same objective function as the Elastic Net with \(11\_\text{ratio}=1.0\) (no L2 penalty).

Read more in the *User Guide*.

**Parameters**

- **alpha** [float, optional] Constant that multiplies the L1 term. Defaults to 1.0. \(\alpha = 0\) is equivalent to an ordinary least square, solved by the *LinearRegression* object. For numerical reasons, using \(\alpha = 0\) with the Lasso object is not advised. Given this, you should use the *LinearRegression* object.

- **fit_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

- **normalize** [boolean, optional, default False] This parameter is ignored when **fit_intercept** is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling *fit* on an estimator with *normalize=False*.

- **precompute** [True | False | array-like, default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

- **max_iter** [int, optional] The maximum number of iterations

- **tol** [float, optional] The tolerance for the optimization: if the updates are smaller than \(\text{tol}\), the optimization code checks the dual gap for optimality and continues until it is smaller than \(\text{tol}\).

- **warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the *Glossary*.

- **positive** [bool, optional] When set to True, forces the coefficients to be positive.

- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘random’.

- **selection** [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

**Attributes**

- **coef_** [array, shape (n_features,) | (n_targets, n_features)] parameter vector (w in the cost function formula)

- **sparse_coef_** [scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)] sparse representation of the fitted coef_

- **intercept_** [float | array, shape (n_targets,)] independent term in decision function.

- **n_iter_** [int | array-like, shape (n_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

lars_path
lasso_path
LassoLars
LassoCV
LassoLarsCV
sklearn.decomposition.sparse_encode

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1)
>>> print(clf.coef_)
[0.85  0.  ]
>>> print(clf.intercept_)
0.15...
```

Methods

__init__

```
__init__(self, alpha=1.0, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')
```

Initialize self. See help(type(self)) for accurate signature.

fit

```
fit(self, X, y[, check_input])
```

Fit model with coordinate descent.

Parameters

- `X` [ndarray or scipy.sparse matrix, (n_samples, n_features)] Data
- `y` [ndarray, shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X’s dtype if necessary
check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{2 \times \text{n\_samples}} \times ||y - Xw||^2_2 \\
+ \alpha \times l1\_ratio \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
(\frac{1}{2 \times \text{n\_samples}}) \times ||Y - XW||^{\text{Fro}}_2 \\
+ \alpha \times l1\_ratio \times ||W||_{21} \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||_{\text{Fro}}^2
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [[array-like], shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.
n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.

precompute [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

coeff_init [array, shape (n_features, ) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coeffs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (self, X)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (self, X, y, sample_weight=None)
    Return the coefficient of determination R^2 of the prediction.
    The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

    Parameters
        X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
        y [array-like of shape (n_samples,)] or (n_samples, n_outputs) True values for X.
        sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

    Returns
        score [float] R^2 of self.predict(X) wrt. y.

    Notes
        The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

    set_params (self, **params)
        Set the parameters of this estimator.
        The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

        Parameters
            **params [dict] Estimator parameters.

        Returns
            self [object] Estimator instance.

    property sparse_coef_
        sparse representation of the fitted coef_

Examples using sklearn.linear_model.Lasso

- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Lasso on dense and sparse data
- Joint feature selection with multi-task Lasso
- Lasso and Elastic Net for Sparse Signals
- Cross-validation on diabetes Dataset Exercise
Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times \| y - Xw \|_2^2 + \alpha \times \| w \|_1
\]

Read more in the User Guide.

**Parameters**

- **alpha** [float, default=1.0] Constant that multiplies the penalty term. Defaults to 1.0. \( \alpha = 0 \) is equivalent to an ordinary least square, solved by `LinearRegression`. For numerical reasons, using \( \alpha = 0 \) with the LassoLars object is not advised and you should prefer the `LinearRegression` object.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- **verbose** [bool or int, default=False] Sets the verbosity amount.

- **normalize** [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors \( X \) will be normalized before regression by subtracting the mean and dividing by the L2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

- **precompute** [bool, ‘auto’ or array-like, default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **max_iter** [int, default=500] Maximum number of iterations to perform.

- **eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization. By default, `np.finfo(np.float).eps` is used.

- **copy_X** [bool, default=True] If True, \( X \) will be copied; else, it may be overwritten.

- **fit_path** [bool, default=True] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to False will lead to a speedup, especially with a small \( \alpha \).

- **positive** [bool, default=False] Restrict coefficients to be \( \geq 0 \). Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of \( \alpha \). Only coefficients up to the smallest \( \alpha \) value (\( \text{alphas}_[\text{alphas} > 0.].\min() \) when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

**Attributes**

- **alphas_** [array-like of shape (n_alphas + 1,) | list of n_targets such arrays] Maximum of covariances (in absolute value) at each iteration. \( n_{\text{alphas}} \) is either `max_iter`,
n_features, or the number of nodes in the path with correlation greater than alpha, whichever is smaller.

active_  [list, length = n_alphas | list of n_targets such lists] Indices of active variables at the end of the path.

coeff_path_  [array-like of shape (n_features, n_alphas + 1) or list] If a list is passed it's expected to be one of n_targets such arrays. The varying values of the coefficients along the path. It is not present if the fit_path parameter is False.

coeff_  [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

intercept_  [float or array-like of shape (n_targets,)] Independent term in decision function.

n_iter_  [array-like or int.] The number of iterations taken by lars_path to find the grid of alphas for each target.

Examples

```python
>>> from sklearn import linear_model
>>> reg = linear_model.LassoLars(alpha=0.01)
>>> reg.fit([[-1, 1], [0, 0], [1, 1]], [-1, 0, -1])
LassoLars(alpha=0.01)
>>> print(reg.coef_)
[ 0. -0.963257...]
```

Methods

- `fit(self, X, y[, Xy])`  Fit the model using X, y as training data.
- `get_params(self[, deep])`  Get parameters for this estimator.
- `predict(self, X)`  Predict using the linear model.
- `score(self, X, y[, sample_weight])`  Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)`  Set the parameters of this estimator.

```python
__init__ (self, alpha=1.0, fit_intercept=True, verbose=False, normalize=True, precompute='auto', max_iter=500, eps=2.220446049250313e-16, copy_X=True, fit_path=True, positive=False)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y, Xy=None)
```
Fit the model using X, y as training data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] \( \text{Xy} = \text{np.dot(X.T, y)} \) that can be precomputed. It is useful only when the Gram matrix is precomputed.

**Returns**

- **self** [object] returns an instance of self.

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(self, X)*

Predict using the linear model.

**Parameters**

- **X** [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score** *(self, X, y, sample_weight=None)*

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \( (y_{true} - y_{pred})^2 \) and \( v \) is the total sum of squares \( (y_{true} - y_{true.mean})^2 \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] \( R^2 \) of self.predict(X) wrt. \( y \).
Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer ’r2’ uses `multioutput='uniform_average'`).

`set_params` *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

`scklearn.linear_model.OptogonalMatchingPursuit`

class `sklearn.linear_model.OptogonalMatchingPursuit` *(n_nonzero_coefs=None, tol=None, fit_intercept=True, normalize=True, precompute='auto')*

Orthogonal Matching Pursuit model (OMP)

Read more in the User Guide.

Parameters

- **n_nonzero_coefs** [int, optional] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
- **tol** [float, optional] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.
- **fit_intercept** [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [boolean, optional, default True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling fit on an estimator with normalize=False.
- **precompute** [(True, False, ‘auto’), default ‘auto’] Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when n_targets or n_samples is very large. Note that if you already have such matrices, you can pass them directly to the fit method.

Attributes

- **coef_** [array, shape (n_features,) or (n_targets, n_features)] parameter vector (w in the formula)
- **intercept_** [float or array, shape (n_targets,)] independent term in decision function.
- **n_iter_** [int or array-like] Number of active features across every target.

Notes

Orthogonal matching pursuit was introduced in G. Mallat, Z. Zhang, Matching pursuits with time-frequency
(http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of
https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf

Examples

```python
>>> from sklearn.linear_model import OrthogonalMatchingPursuit
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(noise=4, random_state=0)
>>> reg = OrthogonalMatchingPursuit().fit(X, y)
>>> reg.score(X, y)
0.9991...
>>> reg.predict(X[:1,])
array([-78.3854...])
```

</tbody>
</table>

```python
__init__ (self, n_nonzero_coefs=None, tol=None, fit_intercept=True, normalize=True, precompute='auto')
Initialize self. See help(type(self)) for accurate signature.
```

```python
fit (self, X, y)
Fit the model using X, y as training data.

Parameters

X [array-like, shape (n_samples, n_features)] Training data.
```
y [array-like, shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtype if necessary

Returns

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer ‘r2’ uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.

2056 Chapter 7. API Reference
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**Examples using sklearn.linear_model.OrthogonalMatchingPursuit**

- Orthogonal Matching Pursuit

**7.22.4 Bayesian regressors**

| sklearn.linear_model.ARDRegression([|n_iter, tol, Bayesian ARD regression. |
| linear_model.BayesianRidge([|n_iter, tol, Bayesian ridge regression. |

**sklearn.linear_model.ARDRegression**

class sklearn.linear_model.ARDRegression(n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization).

Read more in the User Guide.

**Parameters**

n_iter [int, default=300] Maximum number of iterations.

tol [float, default=1e-3] Stop the algorithm if w has converged.

alpha_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.

alpha_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.

lambda_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.

lambda_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.
compute_score [bool, default=False] If True, compute the objective function at each step of the model.

threshold_lambda [float, default=10000] threshold for removing (pruning) weights with high precision from the computation.

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

verbose [bool, default=False] Verbose mode when fitting the model.

Attributes

coef_ [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)

alpha_ [float] estimated precision of the noise.

lambda_ [array-like of shape (n_features,)] estimated precisions of the weights.

sigma_ [array-like of shape (n_features, n_features)] estimated variance-covariance matrix of the weights

scores_ [float] if computed, value of the objective function (to be maximized)

intercept_ [float] Independent term in decision function. Set to 0.0 if fit_intercept = False.

Notes

For an example, see examples/linear_model/plot_ard.py.

__init__ (self, n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y)
```

Fit the ARDRegression model according to the given training data and parameters.

Iterative procedure to maximize the evidence

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values (integers). Will be cast to X’s dtype if necessary

Returns

- **self** [returns an instance of self.]

```python
get_params (self, deep=True)
```

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

```python
predict (self, X, return_std=False)
```

Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Samples.
- **return_std** [bool, default=False] Whether to return the standard deviation of posterior prediction.

Returns

- **y_mean** [array-like of shape (n_samples,)] Mean of predictive distribution of query points.
- **y_std** [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.
score(self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - \bar{y}_{true})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.
Bayesian ridge regression.

Fit a Bayesian ridge model. See the Notes section for details on this implementation and the optimization of the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the *User Guide*.

**Parameters**

- **n_iter** [int, default=300] Maximum number of iterations. Should be greater than or equal to 1.
- **tol** [float, default=1e-3] Stop the algorithm if w has converged.
- **alpha_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.
- **alpha_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.
- **lambda_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.
- **lambda_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.
- **alpha_init** [float, default=None] Initial value for alpha (precision of the noise). If not set, alpha_init is 1/Var(y).
  
  New in version 0.22.
- **lambda_init** [float, default=None] Initial value for lambda (precision of the weights). If not set, lambda_init is 1.
  
  New in version 0.22.
- **compute_score** [bool, default=False] If True, compute the log marginal likelihood at each iteration of the optimization.
- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. The intercept is not treated as a probabilistic parameter and thus has no associated variance. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling fit on an estimator with normalize=False.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **verbose** [bool, default=False]Verbose mode when fitting the model.

**Attributes**

- **coef_** [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)
intercept_ [float] Independent term in decision function. Set to 0.0 if fit_intercept = False.

alpha_ [float] Estimated precision of the noise.

lambda_ [float] Estimated precision of the weights.

sigma_ [array-like of shape (n_features, n_features)] Estimated variance-covariance matrix of the weights.

scores_ [array-like of shape (n_iter_+1,)] If computed_score is True, value of the log marginal likelihood (to be maximized) at each iteration of the optimization. The array starts with the value of the log marginal likelihood obtained for the initial values of alpha and lambda and ends with the value obtained for the estimated alpha and lambda.

n_iter_ [int] The actual number of iterations to reach the stopping criterion.

Notes

There exist several strategies to perform Bayesian ridge regression. This implementation is based on the algorithm described in Appendix A of (Tipping, 2001) where updates of the regularization parameters are done as suggested in (MacKay, 1992). Note that according to A New View of Automatic Relevance Determination (Wipf and Nagarajan, 2008) these update rules do not guarantee that the marginal likelihood is increasing between two consecutive iterations of the optimization.

__init__ (self, n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, alpha_init=None, lambda_init=None, compute_score=False, fit_intercept=True, normalize=False, copy_X=True, verbose=False)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y, sample_weight=None)
Fit the model

Parameters
X [ndarray of shape (n_samples, n_features)] Training data
y [ndarray of shape (n_samples,)] Target values. Will be cast to X’s dtype if necessary
sample_weight [ndarray of shape (n_samples,), default=None] Individual weights for each sample

Returns
self [returns an instance of self.]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

predict (self, X, return_std=False)
Predict using the linear model.
In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.
return_std [bool, default=False] Whether to return the standard deviation of posterior prediction.

Returns
y_mean [array-like of shape (n_samples,)] Mean of predictive distribution of query points.
y_std [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.

score (self, X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,
n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.linear_model.BayesianRidge

- Feature agglomeration vs. univariate selection
- Curve Fitting with Bayesian Ridge Regression
- Bayesian Ridge Regression
- Imputing missing values with variants of IterativeImputer

7.22.5 Multi-task linear regressors with variable selection

These estimators fit multiple regression problems (or tasks) jointly, while inducing sparse coefficients. While the inferred coefficients may differ between the tasks, they are constrained to agree on the features that are selected (non-zero coefficients).

```
linear_model.MultiTaskElasticNet([alpha, ...]) Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer
linear_model.MultiTaskLasso([alpha, ...]) Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.
```

Continued on next page
Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer

The optimization objective for MultiTaskElasticNet is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times \|Y - XW\|_{\text{Fro}}^2 + \alpha \times l1_{\text{ratio}} \times \|W\|_{21} + 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times \|W\|_{\text{Fro}}^2
\]

Where:

\[\|W\|_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **alpha** [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0
- **l1_ratio** [float] The ElasticNet mixing parameter, with 0 < l1_ratio <= 1. For l1_ratio = 1 the penalty is an L1/L2 penalty. For l1_ratio = 0 it is an L2 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1/L2 and L2.
- **fit_intercept** [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **max_iter** [int, optional] The maximum number of iterations
- **tol** [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.
- **warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.
- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘cyclic’.
selection [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

intercept_ [array, shape (n_tasks,)] Independent term in decision function.

t_ [array, shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), t_ is then a 1D array. Note that t_ stores the transpose of W, W.T.

n_iter_ [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

MultiTaskElasticNet Multi-task L1/L2 ElasticNet with built-in cross-validation.

ElasticNet

MultiTaskLasso

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskElasticNet(alpha=0.1)
>>> print(clf.coef_)
[[0.45663524 0.45612256]
 [0.45663524 0.45612256]]
>>> print(clf.intercept_)
[0.0872422 0.0872422]
```

__init__ (self, alpha=1.0, l1_ratio=0.5, fit_intercept=True, normalize=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, random_state=None, selection='cyclic')

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)

Fit MultiTaskElasticNet model with coordinate descent

Parameters

X [ndarray, shape (n_samples, n_features)] Data
y [ndarray, shape (n_samples, n_tasks)] Target. Will be cast to X’s dtype if necessary

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{2 \times n_{\text{samples}}} \|y - Xw\|_2^2 + \alpha \times l1\_ratio \times \|w\|_1 + 0.5 \times \alpha \times (1 - l1\_ratio) \times \|w\|_2^2
\]

For multi-output tasks it is:

\[
\frac{1}{2 \times n_{\text{samples}}} \|Y - XW\|_{\text{Fro}}^2 + \alpha \times l1\_ratio \times \|W\|_{21} + 0.5 \times \alpha \times (1 - l1\_ratio) \times \|W\|_{\text{Fro}}^2
\]

Where:

\[
\|W\|_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters
X [array-like], shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,)] or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.

precompute [True | False | ’auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ’auto’ let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

coeff_init [array, shape (n_features, ) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coeefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

MultiTaskElasticNet
MultiTaskElasticNetCV
ElasticNet
ElasticNetCV
Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

def predict(self, X)
    Predict using the linear model.

    Parameters
    X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

    Returns
    C [array, shape (n_samples,)] Returns predicted values.

def score(self, X, y, sample_weight=None)
    Return the coefficient of determination R^2 of the prediction.
    The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares
    ((y_true - y_pred) ** 2).sum() and v is the total sum of squares
    ((y_true - y_true.mean()) ** 2).sum(). The best possible score
    is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model
    that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

    Parameters
    X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may
    be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,
    n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for
    the estimator.

    y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

    sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

    Returns
    score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average'
from version 0.23 to keep consistent with r2_score. This will influence the score method of
all the multioutput regressors (except for MultiOutputRegressor). To specify the default value
manually and avoid the warning, please either call r2_score directly or make a custom scorer with
make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

def set_params(self, **params)
    Set the parameters of this estimator.

    The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

    Parameters
    **params [dict] Estimator parameters.

    Returns
    self [object] Estimator instance.

property sparse_coef_
sparse representation of the fitted coef_
Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n_{samples})} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_{21}
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

**Parameters**

- **alpha** [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0
- **fit_intercept** [boolean] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **max_iter** [int, optional] The maximum number of iterations
- **tol** [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.
- **warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.
- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘random’.
- **selection** [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4

**Attributes**

- **coef_** [array, shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). Note that coef_ stores the transpose of W, W.T.
- **intercept_** [array, shape (n_tasks,)] independent term in decision function.
- **n_iter_** [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

**MultiTaskLasso**  Multi-task L1/L2 Lasso with built-in cross-validation

**Lasso**

**MultiTaskElasticNet**

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskLasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskLasso(alpha=0.1)
>>> print(clf.coef_)
[[0.89393398 0. ]
 [0.89393398 0. ]]
>>> print(clf.intercept_)
[0.10606602 0.10606602]
```

__init__ (self, alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, random_state=None, selection='cyclic')

Initialize self. See help(type(self)) for accurate signature.

`fit(self, X, y)`

Fit MultiTaskElasticNet model with coordinate descent

Parameters

- **X** [ndarray, shape (n_samples, n_features)] Data
- **y** [ndarray, shape (n_samples, n_tasks)] Target. Will be cast to X’s dtype if necessary
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n\text{\_samples})} ||y - Xw||^2_2 + \alpha \times l1\text{\_ratio} \times ||w||_1 + 0.5 \times \alpha \times (1 - l1\text{\_ratio}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\left(\frac{1}{(2 \times n\text{\_samples})}\right) \times ||Y - XW||_{Fro}^2 + \alpha \times l1\text{\_ratio} \times ||W||_21 + 0.5 \times \alpha \times (1 - l1\text{\_ratio}) \times ||W||_{Fro}^2
\]

Where:

\[
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [[array-like], shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.
precompute [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

ccoef_init [array, shape (n_features,) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

See also:

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (self, X)

Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.
score (self, X, y, sample_weight=None)
    Return the coefficient of determination R^2 of the prediction.

    The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) **
    2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score
    is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always
    predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

    Parameters
    X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may
    be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,
    n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for
    the estimator.

    y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

    sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

    Returns
    score [float] R^2 of self.predict(X) wrt. y.

Notes

    The R2 score used when calling score on a regressor will use multioutput='uniform_average'
    from version 0.23 to keep consistent with r2_score. This will influence the score method of
    all the multioutput regressors (except for MultiOutputRegressor). To specify the default value
    manually and avoid the warning, please either call r2_score directly or make a custom scorer with
    make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
    Set the parameters of this estimator.

    The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
    parameters of the form <component>__<parameter> so that it's possible to update each component
    of a nested object.

    Parameters
    **params [dict] Estimator parameters.

    Returns
    self [object] Estimator instance.

    property sparse_coef_
        sparse representation of the fitted coef_

Examples using sklearn.linear_model.MultiTaskLasso

    • Joint feature selection with multi-task Lasso

7.22.6 Outlier-robust regressors

    Any estimator using the Huber loss would also be robust to outliers, e.g. SGDRegressor with loss='huber'.

Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where \(|(y - X'w) / \sigma| < \epsilon\) and the absolute loss for the samples where \(|(y - X'w) / \sigma| > \epsilon\), where \(w\) and \(\sigma\) are parameters to be optimized. The parameter \(\sigma\) makes sure that if \(y\) is scaled up or down by a certain factor, one does not need to rescale \(\epsilon\) to achieve the same robustness. Note that this does not take into account the fact that the different features of \(X\) may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the User Guide

New in version 0.18.

**Parameters**

- **epsilon** [float, greater than 1.0, default 1.35] The parameter \(\epsilon\) controls the number of samples that should be classified as outliers. The smaller the \(\epsilon\), the more robust it is to outliers.
- **max_iter** [int, default 100] Maximum number of iterations that scipy.optimize.minimize(method="L-BFGS-B") should run for.
- **alpha** [float, default 0.0001] Regularization parameter.
- **warm_start** [bool, default False] This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit. See the Glossary.
- **fit_intercept** [bool, default True] Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.
- **tol** [float, default 1e-5] The iteration will stop when \(\max(|\text{proj } g_i| \mid i = 1, \ldots, n) \leq \text{tol}\) where \(g_i\) is the i-th component of the projected gradient.

**Attributes**

- **coef_** [array, shape (n_features,)] Features got by optimizing the Huber loss.
- **intercept_** [float] Bias.
- **scale_** [float] The value by which \(|y - X'w - c|\) is scaled down.
- **n_iter_** [int] Number of iterations that scipy.optimize.minimize(method="L-BFGS-B") has run for.

Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed max_iter. n_iter_ will now report at most max_iter.
outliers_ [array, shape (n_samples,)] A boolean mask which is set to True where the samples are identified as outliers.

fit(self, X, y[, sample_weight]) Fit the model according to the given training data.
get_params(self[, deep]) Get parameters for this estimator.
predict(self, X) Predict using the linear model.
score(self, X, y[, sample_weight]) Return the coefficient of determination R^2 of the prediction.
set_params(self, **params) Set the parameters of this estimator.
```

__init__ (self, epsilon=1.35, max_iter=100, alpha=0.0001, warm_start=False, fit_intercept=True, tol=1e-05)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y, sample_weight=None)

Fit the model according to the given training data.

Parameters

- X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- y [array-like, shape (n_samples,)] Target vector relative to X.
- sample_weight [array-like, shape (n_samples,)] Weight given to each sample.
get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) **
2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score
is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always
predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may
be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,

n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for
the estimator.

y [array-like of shape (n_samples,)] or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average'
from version 0.23 to keep consistent with r2_score. This will influence the score method of
all the multioutput regressors (except for MultiOutputRegressor). To specify the default value
manually and avoid the warning, please either call r2_score directly or make a custom scorer with
make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.linear_model.HuberRegressor

- HuberRegressor vs Ridge on dataset with strong outliers
- Robust linear estimator fitting

sklearn.linear_model.RANSACRegressor

class sklearn.linear_model.RANSACRegressor(base_estimator=None, min_samples=None, residual_threshold=None, is_data_valid=None, is_model_valid=None, max_trials=100, max_skips=inf, stop_n_inliers=inf, stop_score=inf, stop_probability=0.99, loss='absolute_loss', random_state=None)

RANSAC (RANdom SAmple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set.

Read more in the User Guide.

Parameters

- **base_estimator** [object, optional] Base estimator object which implements the following methods:
  - fit(X, y): Fit model to given training data and target values.
  - score(X, y): Returns the mean accuracy on the given test data, which is used for the stop criterion defined by stop_score. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.
  - predict(X): Returns predicted values using the linear model, which is used to compute residual error using loss function.

If base_estimator is None, then base_estimator=sklearn.linear_model.LinearRegression() is used for target values of dtype float.

Note that the current implementation only supports regression estimators.

- **min_samples** [int (>= 1) or float ([0, 1]), optional] Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for min_samples >= 1, treated as a relative number ceil(min_samples * X.shape[0]) for min_samples < 1. This is typically chosen as the minimal number of samples necessary to estimate the given base_estimator. By default a sklearn.linear_model.LinearRegression() estimator is assumed and min_samples is chosen as X.shape[1] + 1.

- **residual_threshold** [float, optional] Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values y.
is_data_valid [callable, optional] This function is called with the randomly selected data before the model is fitted to it: is_data_valid(X, y). If its return value is False the current randomly chosen sub-sample is skipped.

is_model_valid [callable, optional] This function is called with the estimated model and the randomly selected data: is_model_valid(model, X, y). If its return value is False the current randomly chosen sub-sample is skipped. Rejecting samples with this function is computationally costlier than with is_data_valid. is_model_valid should therefore only be used if the estimated model is needed for making the rejection decision.

max_trials [int, optional] Maximum number of iterations for random sample selection.

max_skips [int, optional] Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by is_data_valid or invalid models defined by is_model_valid.

New in version 0.19.

stop_n_inliers [int, optional] Stop iteration if at least this number of inliers are found.

stop_score [float, optional] Stop iteration if score is greater equal than this threshold.

stop_probability [float in range [0, 1], optional] RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least N samples (iterations):

\[
N >= \log(1 - \text{probability}) / \log(1 - e^{\ast m})
\]

where the probability (confidence) is typically set to high value such as 0.99 (the default) and e is the current fraction of inliers w.r.t. the total number of samples.

loss [string, callable, optional, default “absolute_loss”] String inputs, “absolute_loss” and “squared_loss” are supported which find the absolute loss and squared loss per sample respectively.

If loss is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the i-th value of the array corresponding to the loss on X[i].

If the loss on a sample is greater than the residual_threshold, then this sample is classified as an outlier.

random_state [int, RandomState instance or None, optional, default None] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

estimator_ [object] Best fitted model (copy of the base_estimator object).

n_trials_ [int] Number of random selection trials until one of the stop criteria is met. It is always <= max_trials.

inlier_mask_ [bool array of shape [n_samples]] Boolean mask of inliers classified as True.

n_skips_no_inliers_ [int] Number of iterations skipped due to finding zero inliers.

New in version 0.19.

n_skips_invalid_data_ [int] Number of iterations skipped due to invalid data defined by is_data_valid.

New in version 0.19.
n_skips_invalid_model_ [int] Number of iterations skipped due to an invalid model defined by is_model_valid.

New in version 0.19.

Examples

```python
>>> from sklearn.linear_model import RANSACRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression...
>>> reg = RANSACRegressor(random_state=0).fit(X, y)
>>> reg.score(X, y)
0.9885...
>>> reg.predict(X[:1,])
array([-31.9417...])
```

Methods

- `fit(self, X, y[, sample_weight])` Fit estimator using RANSAC algorithm.
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, X)` Predict using the estimated model.
- `score(self, X, y)` Returns the score of the prediction.
- `set_params(self, **params)` Set the parameters of this estimator.

```
__init__(self, base_estimator=None, min_samples=None, residual_threshold=None,
         is_data_valid=None, is_model_valid=None, max_trials=100, max_skips=inf,
         stop_n_inliers=inf, stop_score=inf, stop_probability=0.99, loss='absolute_loss',
         random_state=None)
```

Initialize self. See help(type(self)) for accurate signature.

- `fit (self, X, y, sample_weight=None)`
  Fit estimator using RANSAC algorithm.

  Parameters

  - **X** [array-like or sparse matrix, shape [n_samples, n_features]] Training data.
  - **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
  - **sample_weight** [array-like of shape (n_samples,), default=None] Individual weights for each sample raises error if sample_weight is passed and base_estimator fit method does not support it.

  Raises

  - `ValueError` If no valid consensus set could be found. This occurs if is_data_valid and is_model_valid return False for all max_trials randomly chosen sub-samples.

- `get_params (self, deep=True)`
  Get parameters for this estimator.
Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)

Predict using the estimated model.

This is a wrapper for estimator_.predict(X).

Parameters

X [numpy array of shape [n_samples, n_features]]

Returns

y [array, shape = [n_samples] or [n_samples, n_targets]] Returns predicted values.

score (self, X, y)

Returns the score of the prediction.

This is a wrapper for estimator_.score(X, y).

Parameters

X [numpy array or sparse matrix of shape [n_samples, n_features]] Training data.

y [array, shape = [n_samples] or [n_samples, n_targets]] Target values.

Returns

z [float] Score of the prediction.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.linear_model.RANSACRegressor

- Robust linear model estimation using RANSAC
- Theil-Sen Regression
- Robust linear estimator fitting
Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size n_subsamples of the samples in X. Any value of n_subsamples between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is “n_samples choose n_subsamples”, it can be extremely large and can therefore be limited with max_subpopulation. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions.

Read more in the User Guide.

Parameters

- **fit_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.
- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **max_subpopulation** [int, optional, default 1e4] Instead of computing with a set of cardinality ‘n choose k’, where n is the number of samples and k is the number of subsamples (at least number of features), consider only a stochastic subpopulation of a given maximal size if ‘n choose k’ is larger than max_subpopulation. For other than small problem sizes this parameter will determine memory usage and runtime if n_subsamples is not changed.
- **n_subsamples** [int, optional, default None] Number of samples to calculate the parameters. This is at least the number of features (plus 1 if fit_intercept=True) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of subsamples leading to maximal robustness. If n_subsamples is set to n_samples, Theil-Sen is identical to least squares.
- **max_iter** [int, optional, default 300] Maximum number of iterations for the calculation of spatial median.
- **tol** [float, optional, default 1.e-3] Tolerance when calculating spatial median.
- **random_state** [int, RandomState instance or None, optional, default None] A random number generator instance to define the state of the random permutations generator. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **n_jobs** [int or None, optional (default=None)] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **verbose** [boolean, optional, default False] Verbose mode when fitting the model.

Attributes

- **coef_** [array, shape = (n_features)] Coefficients of the regression model (median of distribution).
- **intercept_** [float] Estimated intercept of regression model.
- **breakdown_** [float] Approximated breakdown point.
- **n_iter_** [int] Number of iterations needed for the spatial median.
n_subpopulation_ [int] Number of combinations taken into account from ‘n choose k’, where n is the number of samples and k is the number of subsamples.

References

Examples

```python
>>> from sklearn.linear_model import TheilSenRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_samples=200, n_features=2, noise=4.0, random_state=0)
>>> reg = TheilSenRegressor(random_state=0).fit(X, y)
>>> reg.score(X, y)
0.9884...
>>> reg.predict(X[:1,])
array([-31.5871...])
```

Methods

- **fit**(self, X, y) Fit linear model.
- **get_params**(self[, deep]) Get parameters for this estimator.
- **predict**(self, X) Predict using the linear model.
- **score**(self, X, y[, sample_weight]) Return the coefficient of determination R^2 of the prediction.
- **set_params**(self, **params) Set the parameters of this estimator.

```
__init__(self, fit_intercept=True, copy_X=True, max_subpopulation=10000.0, n_subsamples=None, max_iter=300, tol=0.001, random_state=None, n_jobs=None, verbose=False)
Initialize self. See help(type(self)) for accurate signature.
```

```
fit (self, X, y)
Fit linear model.

Parameters

X [numpy array of shape [n_samples, n_features]] Training data
y [numpy array of shape [n_samples]] Target values

Returns

self [returns an instance of self.]
```

```
get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
```

7.22. sklearn.linear_model: Linear Models 2083
**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the linear model.

**Parameters**

- *X* [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- *C* [array, shape (n_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- *X* [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- *y* [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- *sample_weight* [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- score [float] R^2 of self.predict(X) wrt. y.

**Notes**

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

**set_params** (*self*, **params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

Examples using sklearn.linear_model.TheilSenRegressor

- Theil-Sen Regression
- Robust linear estimator fitting

7.22.7 Miscellaneous

### Linear Model Functions

- `sklearn.linear_model.PassiveAggressiveRegressor`
  - Parameters:
    - **C** [float] Maximum step size (regularization). Defaults to 1.0.
    - **fit_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.
    - **max_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit` method.
      - New in version 0.19.
    - **tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when `(loss > previous_loss - tol)`. New in version 0.19.
    - **early_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of

### Example Code

```python
sklearn.linear_model.PassiveAggressiveRegressor (C=1.0,           fit_intercept=True,  
                                              max_iter=1000,      tol=0.001,  
                                              early_stopping=False, validation_fraction=0.1,  
                                              n_iter_no_change=5, shuffle=True, verbose=0, loss='epsilon_insensitive',  
                                              epsilon=0.1, random_state=None, warm_start=False, average=False)
```

Passive Aggressive Regressor

Read more in the User Guide.
training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

**validation_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

**n_iter_no_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, optional] The verbosity level

**loss** [string, optional] The loss function to be used: epsilon_insensitive: equivalent to PA-I in the reference paper. squared_epsilon_insensitive: equivalent to PA-II in the reference paper.

**epsilon** [float] If the difference between the current prediction and the correct label is below this threshold, the model is not updated.

**random_state** [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter average to use weights averaging in SGD

Attributes

**coef_** [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

**intercept_** [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

**n_iter_** [int] The actual number of iterations to reach the stopping criterion.

**t_** [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

See also:

*SGDRegressor*

Examples

```python
>>> from sklearn.linear_model import PassiveAggressiveRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, random_state=0)
>>> regr = PassiveAggressiveRegressor(max_iter=100, random_state=0, ... tol=1e-3)
>>> regr.fit(X, y)
PassiveAggressiveRegressor(max_iter=100, random_state=0)

>>> print(regr.coef_)
[20.48736655 34.18818427 67.59122734 87.94731329]

>>> print(regr.intercept_)
[-0.02306214]

>>> print(regr.predict([[0, 0, 0, 0]]))
[-0.02306214]
```

sklearn.linear_model.enet_path

sklearn.linear_model.enet_path(X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs. For mono-output tasks it is:

$$
\frac{1}{(2 \times n_samples)} \times ||y - Xw||^2_2 \\
+ alpha \times l1_ratio \times ||w||_1 \\
+ 0.5 \times alpha \times (1 - l1_ratio) \times ||w||^2_2
$$

For multi-output tasks it is:

$$
\frac{1}{(2 \times n_samples)} \times \sum Y - XW||^Fro_2 \\
+ alpha \times l1_ratio \times \sum ||w||_21 \\
+ 0.5 \times alpha \times (1 - l1_ratio) \times \sum ||w||_Fro^2
$$

Where:

$$
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
$$

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X ([array-like], shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.
y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.

precompute [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

coef_init [array, shape (n_features, ) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.
Examples using `sklearn.linear_model.enet_path`

- Lasso and Elastic Net

`sklearn.linear_model.lars_path`

```python
sklearn.linear_model.lars_path(X, y, Xy=None, Gram=None, max_iter=500, alpha_min=0,
method='lar', copy_X=True, eps=2.220446049250313e-16, copy_Gram=True, verbose=0, return_path=True, return_n_iter=False, positive=False)
```

Compute Least Angle Regression or Lasso path using LARS algorithm [1]

The optimization objective for the case method='lasso' is:

\[
\frac{1}{(2 \times n_{samples})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

in the case of method='lars', the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the User Guide.

**Parameters**

- X [None or array-like of shape (n_samples, n_features)] Input data. Note that if X is None then the Gram matrix must be specified, i.e., cannot be None or False.
  
  Deprecated since version 0.21: The use of X is None in combination with Gram is not False will be removed in v0.23. Use lars_path_gram instead.

- y [None or array-like of shape (n_samples,)] Input targets.

- Xy [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

- Gram [None, ‘auto’, array-like of shape (n_features, n_features), default=None] Precomputed Gram matrix (X' * X), if ‘auto’, the Gram matrix is precomputed from the given X, if there are more samples than features.
  
  Deprecated since version 0.21: The use of X is None in combination with Gram is not False will be removed in v0.23. Use lars_path_gram instead.

- max_iter [int, default=500] Maximum number of iterations to perform, set to infinity for no limit.

- alpha_min [float, default=0] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.

- copy_X [bool, default=True] If False, X is overwritten.

- eps [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. By default, np.finfo(np.float).eps is used.

- copy_Gram [bool, default=True] If False, Gram is overwritten.

- verbose [int, default=0] Controls output verbosity.
return_path [bool, default=True] If return_path=True returns the entire path, else returns only the last point of the path.

return_n_iter [bool, default=False] Whether to return the number of iterations.

positive [bool, default=False] Restrict coefficients to be >= 0. This option is only allowed with method ‘lasso’. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.

Returns

alphas [array-like of shape (n_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.

active [array-like of shape (n_alphas,)] Indices of active variables at the end of the path.

coefs [array-like of shape (n_features, n_alphas + 1)] Coefficients along the path

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

Examples using sklearn.linear_model.lars_path

- Lasso path using LARS

sklearn.linear_model.lars_path_gram

sklearn.linear_model.lars_path_gram(Xy, Gram, n_samples, max_iter=500, alpha_min=0, method='lar', copy_X=True, eps=2.220446049250313e-16, copy_Gram=True, verbose=0, return_path=True, return_n_iter=False, positive=False)

lars_path in the sufficient stats mode [1]

The optimization objective for the case method='lasso' is:
\[(1 / (2 + n_{samples})) \times ||y - Xw||^2_2 + \alpha \times ||w||_1\]

in the case of method=’lars’, the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the **User Guide**.

**Parameters**

- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets)] Xy = np.dot(X.T, y).
- **Gram** [array-like of shape (n_features, n_features)] Gram = np.dot(X.T * X).
- **n_samples** [int or float] Equivalent size of sample.
- **max_iter** [int, default=500] Maximum number of iterations to perform, set to infinity for no limit.
- **alpha_min** [float, default=0] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.
- **method** [{'lar', 'lasso'}, default='lar'] Specifies the returned model. Select 'lar' for Least Angle Regression, 'lasso' for the Lasso.
- **copy_X** [bool, default=True] If False, X is overwritten.
- **eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. By default, np.finfo(np.float).eps is used.
- **copy_Gram** [bool, default=True] If False, Gram is overwritten.
- **verbose** [int, default=0] Controls output verbosity.
- **return_path** [bool, default=True] If return_path==True returns the entire path, else returns only the last point of the path.
- **return_n_iter** [bool, default=False] Whether to return the number of iterations.
- **positive** [bool, default=False] Restrict coefficients to be >= 0. This option is only allowed with method ‘lasso’. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.

**Returns**

- **alphas** [array-like of shape (n_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.
- **active** [array-like of shape (n_alphas,)] Indices of active variables at the end of the path.
- **coefs** [array-like of shape (n_features, n_alphas + 1)] Coefficients along the path
- **n_iter** [int] Number of iterations run. Returned only if return_n_iter is set to True.

sklearn.linear_model.lasso_path

sklearn.linear_model.lasso_path(X, y, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, **params)

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times | | y - Xw | |^2_2 + \alpha \times | | w | |_1
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times | | Y - XW | |^2_{\text{Fro}} + \alpha \times | | W | |_{21}
\]

Where:

\[
| | W | |_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [array-like, sparse matrix], shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,), or (n_samples, n_outputs)] Target values

eps [float, optional] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3

n_alphas [int, optional] Number of alphas along the regularization path

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

precompute [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.
copy_X  [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

coef_init  [array, shape (n_features, ) | None] The initial values of the coefficients.

verbose  [bool or integer] Amount of verbosity.

return_n_iter  [bool] whether to return the number of iterations or not.

positive  [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

params  [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

alphas  [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs  [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps  [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters  [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

lars_path
Lasso
LassoLars
LassoCV
LassoLarsCV
sklearn.decomposition.sparse_encode

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by lars_path.

Examples

Comparing lasso_path and lars_path with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0.         0.         0.46874778]
 [0.2159048  0.4425765  0.23689075]]
```
Examples using sklearn.linear_model.lasso_path

- Lasso and Elastic Net

sklearn.linear_model.orthogonal_mp

sklearn.linear_model.orthogonal_mp(X, y, n_nonzero_coefs=None, tol=None, precompute=False, copy_X=True, return_path=False, return_n_iter=False)

Orthogonal Matching Pursuit (OMP)

Solves n_targets Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using n_nonzero_coefs: argmin ||y - Xgamma||^2 subject to ||gamma||_0 <= n_{nonzero coefs}

When parametrized by error using the parameter tol: argmin ||gamma||_0 subject to ||y - Xgamma||^2 <= tol

Read more in the User Guide.

Parameters

- X [array, shape (n_samples, n_features)] Input data. Columns are assumed to have unit norm.
- y [array, shape (n_samples,) or (n_samples, n_targets)] Input targets
- n_nonzero_coefs [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
- tol [float] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.
- precompute [[True, False, ‘auto’],] Whether to perform precomputations. Improves performance when n_targets or n_samples is very large.
- copy_X [bool, optional] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.
- return_path [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
- return_n_iter [bool, optional default False] Whether or not to return the number of iterations.

Returns

- coef [array, shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If return_path=True, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.
n_iters [array-like or int] Number of active features across every target. Returned only if return_n_iter is set to True.

Notes

sklearn.linear_model.orthogonal_mp_gram

sklearn.linear_model.orthogonal_mp_gram(Gram, Xy, n_nonzero_coefs=None, tol=None, norms_squared=None, copy_Gram=True, copy_Xy=True, return_path=False, return_n_iter=False)

Gram Orthogonal Matching Pursuit (OMP)

Solves n_targets Orthogonal Matching Pursuit problems using only the Gram matrix X.T * X and the product X.T * y.

Read more in the User Guide.

Parameters

Gram [array, shape (n_features, n_features)] Gram matrix of the input data: X.T * X

Xy [array, shape (n_features,) or (n_features, n_targets)] Input targets multiplied by X: X.T * y

n_nonzero_coefs [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol [float] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

norms_squared [array-like, shape (n_targets,)] Squared L2 norms of the lines of y. Required if tol is not None.

copy_Gram [bool, optional] Whether the gram matrix must be copied by the algorithm. A false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.

copy_Xy [bool, optional] Whether the covariance vector Xy must be copied by the algorithm. If False, it may be overwritten.

return_path [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.

Returns

7.22. sklearn.linear_model: Linear Models 2095
**coef** [array, shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If return_path=True, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.

**n_iters** [array-like or int] Number of active features across every target. Returned only if return_n_iter is set to True.

See also:

*OrthogonalMatchingPursuit*

*orthogonal_mp*

*lars_path*

*decomposition.sparse_encode*

**Notes**

**sklearn.linear_model.ridge_regression**

```python
sklearn.linear_model.ridge_regression(X, y, alpha, sample_weight=None, solver='auto', max_iter=None, tol=0.001, verbose=0, random_state=None, return_n_iter=False, return_intercept=False, check_input=True)
```

Solve the ridge equation by the method of normal equations.

Read more in the User Guide.

**Parameters**

- **X** [[ndarray, sparse matrix, LinearOperator] of shape (n_samples, n_features)] Training data
- **y** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values
- **alpha** [float or array-like of shape (n_targets,)] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $C^{-1}$ in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.
- **sample_weight** [float or array-like of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight. If sample_weight is not None and solver='auto', the solver will be set to 'cholesky'.

New in version 0.17.

- **solver** [['auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'], default='auto'] Solver to use in the computational routines:
  - ‘auto’ chooses the solver automatically based on the type of data.
• ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.

• ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution via a Cholesky decomposition of dot(X.T, X)

• ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).

• ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.

• ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse_cg’ supports sparse input when ‘fit_intercept’ is True.

New in version 0.17: Stochastic Average Gradient descent solver.
New in version 0.19: SAGA solver.

max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. For the ‘sparse_cg’ and ‘lsqr’ solvers, the default value is determined by scipy.sparse.linalg. For ‘sag’ and saga solver, the default value is 1000.

tol [float, default=1e-3] Precision of the solution.

verbose [int, default=0] Verbosity level. Setting verbose > 0 will display additional information depending on the solver used.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘sag’.

return_n_iter [bool, default=False] If True, the method also returns n_iter, the actual number of iteration performed by the solver.

New in version 0.17.

return_intercept [bool, default=False] If True and if X is sparse, the method also returns the intercept, and the solver is automatically changed to ‘sag’. This is only a temporary fix for fitting the intercept with sparse data. For dense data, use sklearn.linear_model._preprocess_data before your regression.

New in version 0.17.

check_input [bool, default=True] If False, the input arrays X and y will not be checked.

New in version 0.21.

Returns

coef [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

n_iter [int, optional] The actual number of iteration performed by the solver. Only returned if return_n_iter is True.
intercept [float or ndarray of shape (n_targets,)] The intercept of the model. Only returned if return_intercept is True and if X is a scipy sparse array.

Notes

This function won’t compute the intercept.

7.23 sklearn.manifold: Manifold Learning

The sklearn.manifold module implements data embedding techniques.

User guide: See the Manifold learning section for further details.

7.23.1 sklearn.manifold.Isomap

class sklearn.manifold.Isomap(n_neighbors=5, n_components=2, eigen_solver='auto', tol=0, max_iter=None, path_method='auto', neighbors_algorithm='auto', n_jobs=None, metric='minkowski', p=2, metric_params=None)

Isomap Embedding

Non-linear dimensionality reduction through Isometric Mapping

Read more in the User Guide.

Parameters

- n_neighbors [integer] number of neighbors to consider for each point.
- n_components [integer] number of coordinates for the manifold
- eigen_solver [['auto','arpack','dense']] ‘auto’: Attempt to choose the most efficient solver for the given problem.
- tol [float] Convergence tolerance passed to arpack or lobpcg. not used if eigen_solver == ‘dense’.
- max_iter [integer] Maximum number of iterations for the arpack solver. not used if eigen_solver == ‘dense’.
- path_method [string ['auto','FW','D']] Method to use in finding shortest path.
- neighbors_algorithm [string] Method to use to find the nearest neighbors.
- metric_params [None] Additional keyword arguments for the distance metric used in Isomap.

2098 Chapter 7. API Reference
‘D’ : Dijkstra’s algorithm.

**neighbors_algorithm** [string [‘auto’|’brute’|’kd_tree’|’ball_tree’]] Algorithm to use for nearest
neighbors search, passed to neighbors.NearestNeighbors instance.

**n_jobs** [int or None, default=None] The number of parallel jobs to run. None means 1 unless in
a joblib.parallel_backend context. -1 means using all processors. See Glossary
for more details.

**metric** [string, or callable, default=“minkowski”] The metric to use when calculating distance
between instances in a feature array. If metric is a string or callable, it must be one of
the options allowed by sklearn.metrics.pairwise_distances for its metric param-
eter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square.
X may be a Glossary.

New in version 0.22.

**p** [int, default=2] Parameter for the Minkowski metric from
sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to us-
ing manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p,
minkowski_distance (l_p) is used.

New in version 0.22.

**metric_params** [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.22.

**Attributes**

**embedding_** [array-like, shape (n_samples, n_components)] Stores the embedding vectors.

**kernel_pca_** [object] KernelPCA object used to implement the embedding.

**nbsrs_** [sklearn.neighbors.NearestNeighbors instance] Stores nearest neighbors instance, in-
cluding BallTree or KDtree if applicable.

**dist_matrix_** [array-like, shape (n_samples, n_samples)] Stores the geodesic distance matrix
of training data.

**References**

#### __init__

```
init__(self, n_neighbors=5, n_components=2, eigen_solver='auto', tol=0, max_iter=None,
        path_method='auto', neighbors_algorithm='auto', n_jobs=None, metric='minkowski',
        p=2, metric_params=None)
```

Initialize self. See help(type(self)) for accurate signature.

#### fit

```
fit (self, X, y=None)
```

Compute the embedding vectors for data X

**Parameters**

- **X** ([array-like, sparse graph, BallTree, KDTree, NearestNeighbors]) Sample data, shape = (n_samples, n_features), in the form of a numpy array, sparse graph, precomputed tree, or NearestNeighbors object.
- **y** [Ignored]

**Returns**

- **self**  [returns an instance of self.]

#### fit_transform

```
fit_transform (self, X, y=None)
```

Fit the model from data in X and transform X.

**Parameters**

- **X** ([array-like, sparse graph, BallTree, KDTree]) Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [Ignored]

**Returns**

- **X_new**  [array-like, shape (n_samples, n_components)]

#### get_params

```
get_params (self, deep=True)
```

Get parameters for this estimator.

**Parameters**

- **deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**  [mapping of string to any] Parameter names mapped to their values.

#### reconstruction_error

```
reconstruction_error (self)
```

Compute the reconstruction error for the embedding.

**Returns**

- **reconstruction_error**  [float]
Notes

The cost function of an isomap embedding is

\[ E = \text{frobenius_norm}[K(D) - K(D_{fit})] / n_{samples} \]

Where \( D \) is the matrix of distances for the input data \( X \), \( D_{fit} \) is the matrix of distances for the output embedding \( X_{fit} \), and \( K \) is the isomap kernel:

\[ K(D) = -0.5 * (I - 1/n_{samples}) * D^2 * (I - 1/n_{samples}) \]

**set_params** (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

**transform** (self, X)

Transform X.

This is implemented by linking the points X into the graph of geodesic distances of the training data. First the `n_neighbors` nearest neighbors of X are found in the training data, and from these the shortest geodesic distances from each point in X to each point in the training data are computed in order to construct the kernel. The embedding of X is the projection of this kernel onto the embedding vectors of the training set.

Parameters

X [array-like, shape (n_queries, n_features)] If neighbors_algorithm='precomputed', X is assumed to be a distance matrix or a sparse graph of shape (n_queries, n_samples_fit).

Returns

X_new [array-like, shape (n_queries, n_components)]

Examples using `sklearn.manifold.Isomap`

• Comparison of Manifold Learning methods
• Manifold Learning methods on a severed sphere
• Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…
• Release Highlights for scikit-learn 0.22
7.23.2 sklearn.manifold.LocallyLinearEmbedding

class sklearn.manifold.LocallyLinearEmbedding(n_neighbors=5, n_components=2, reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, neighbors_algorithm='auto', random_state=None, n_jobs=None)

Locally Linear Embedding

Read more in the User Guide.

Parameters

- **n_neighbors** [integer] number of neighbors to consider for each point.
- **n_components** [integer] number of coordinates for the manifold
- **reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.
- **eigen_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data
  - **arpack** [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.
  - **dense** [use standard dense matrix operations for the eigenvalue decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.
- **tol** [float, optional] Tolerance for ‘arpack’ method Not used if eigen_solver=='dense'.
- **max_iter** [integer] maximum number of iterations for the arpack solver. Not used if eigen_solver=='dense'.
- **method** [string ('standard', 'hessian', 'modified' or 'ltsa')]
  - **standard** [use the standard locally linear embedding algorithm. see reference [1]]
  - **hessian** [use the Hessian eigenmap method. This method requires] n_neighbors > n_components * (1 + (n_components + 1) / 2 see reference [2]
  - **modified** [use the modified locally linear embedding algorithm.] see reference [3]
  - **ltsa** [use local tangent space alignment algorithm] see reference [4]
- **hessian_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if method == 'hessian'
- **modified_tol** [float, optional] Tolerance for modified LLE method. Only used if method == 'modified'
- **neighbors_algorithm** [string ['auto', 'brute', 'kd_tree', 'ball_tree']] algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when eigen_solver == ‘arpack’. 
n_jobs [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

embedding_ [array-like, shape [n_samples, n_components]] Stores the embedding vectors
reconstruction_error_ [float] Reconstruction error associated with embedding_
nbrs_ [NearestNeighbors object] Stores nearest neighbors instance, including BallTree or KDtree if applicable.

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import LocallyLinearEmbedding
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = LocallyLinearEmbedding(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

Methods

```python
fit(self, X[, y]) Compute the embedding vectors for data X
fit_transform(self, X[, y]) Compute the embedding vectors for data X and transform X.
get_params(self[, deep]) Get parameters for this estimator.
set_params(self, **params) Set the parameters of this estimator.
transform(self, X) Transform new points into embedding space.
```

```python
__init__(self, n_neighbors=5, n_components=2, reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, neighbors_algorithm='auto', random_state=None, n_jobs=None) Initialize self. See help(type(self)) for accurate signature.
```

```python
fit (self, X, y=None) Compute the embedding vectors for data X
```

Parameters

- **X** [array-like of shape [n_samples, n_features]] training set.
- **y** [Ignored]

Returns

- **self** [returns an instance of self.]
**fit_transform** *(self, X, y=None)*
Compute the embedding vectors for data X and transform X.

**Parameters**
- **X** [array-like of shape [n_samples, n_features]] training set.
- **y** [Ignored]

**Returns**
- **X_new** [array-like, shape (n_samples, n_components)]

**get_params** *(self, deep=True)*
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**
- ****params** [dict] Estimator parameters.

**Returns**
- **self** [object] Estimator instance.

**transform** *(self, X)*
Transform new points into embedding space.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)]

**Returns**
- **X_new** [array, shape = [n_samples, n_components]]

**Notes**
Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

**Examples using sklearn.manifold.LocallyLinearEmbedding**

- Visualizing the stock market structure
- Comparison of Manifold Learning methods
- Manifold Learning methods on a severed sphere
• *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

### 7.23.3 sklearn.manifold.MDS

```python
class sklearn.manifold.MDS(n_components=2, metric=True, n_init=4, max_iter=300, verbose=0, eps=0.001, n_jobs=None, random_state=None, dissimilarity='euclidean')
```

Multidimensional scaling

Read more in the *User Guide*.

**Parameters**

- `n_components` [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities.
- `metric` [boolean, optional, default: True] If `True`, perform metric MDS; otherwise, perform nonmetric MDS.
- `n_init` [int, optional, default: 4] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.
- `verbose` [int, optional, default: 0] Level of verbosity.
- `eps` [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.
- `n_jobs` [int or None, optional (default=None)] The number of jobs to use for the computation. If multiple initializations are used (`n_init`), each run of the algorithm is computed in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.
- `random_state` [int, RandomState instance or None, optional, default: None] The generator used to initialize the centers. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.
- `dissimilarity` ['euclidean' | 'precomputed', optional, default: 'euclidean'] Dissimilarity measure to use:
  - 'euclidean': Pairwise Euclidean distances between points in the dataset.
  - 'precomputed': Pre-computed dissimilarities are passed directly to `fit` and `fit_transform`.

**Attributes**

- `embedding_` [array-like, shape (n_samples, n_components)] Stores the position of the dataset in the embedding space.
- `stress_` [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import MDS

>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = MDS(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

Methods

```python
def fit(self, X[, y, init])
    Computes the position of the points in the embedding space

def fit_transform(self, X[, y, init])
    Fit the data from X, and returns the embedded coordinates

def get_params(self[, deep])
    Get parameters for this estimator.

def set_params(self, **params)
    Set the parameters of this estimator.
```

```python
__init__(self, n_components=2, metric=True, n_init=4, max_iter=300, verbose=0, eps=0.001, n_jobs=None, random_state=None, dissimilarity='euclidean')
```

Initialize self. See help(type(self)) for accurate signature.

```python
def fit(self, X, y=None, init=None)
    Computes the position of the points in the embedding space

    Parameters
    ----------
    X : array, shape (n_samples, n_features) or (n_samples, n_samples)
        Input data. If dissimilarity=='precomputed', the input should be the dissimilarity matrix.
    y : Ignored
    init : ndarray, shape (n_samples,), optional, default: None
        Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.
```

```python
def fit_transform(self, X, y=None, init=None)
    Fit the data from X, and returns the embedded coordinates

    Parameters
    ----------
    X : array, shape (n_samples, n_features) or (n_samples, n_samples)
        Input data. If dissimilarity=='precomputed', the input should be the dissimilarity matrix.
y [Ignored]

init [ndarray, shape (n_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

- **params [dict] Estimator parameters.

Returns

Examples using sklearn.manifold.MDS

- Comparison of Manifold Learning methods
- Multi-dimensional scaling
- Manifold Learning methods on a severed sphere
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

7.23.4 sklearn.manifold.SpectralEmbedding

class sklearn.manifold.SpectralEmbedding (n_components=2, affinity='nearest_neighbors',
 gamma=None, random_state=None,
 eigen_solver=None, n_neighbors=None,
 n_jobs=None)

Spectral embedding for non-linear dimensionality reduction.

Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.

Note: Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the User Guide.

Parameters

- n_components [integer, default: 2] The dimension of the projected subspace.
- affinity [string or callable, default]
How to construct the affinity matrix.

- 'nearest_neighbors' : construct the affinity matrix by computing a graph of nearest neighbors.
- 'rbf' : construct the affinity matrix by computing a radial basis function (RBF) kernel.
- 'precomputed' : interpret $X$ as a precomputed affinity matrix.
- 'precomputed_nearest_neighbors' : interpret $X$ as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the $n_{neighbors}$ nearest neighbors.
- callable : use passed in function as affinity the function takes in data matrix ($n_{samples}$, $n_{features}$) and return affinity matrix ($n_{samples}$, $n_{samples}$).

**gamma** [float, optional, default] Kernel coefficient for rbf kernel.

**random_state** [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigenvectors. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == 'amg'.

**eigen_solver** [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems.

**n_neighbors** [int, default] Number of nearest neighbors for nearest_neighbors graph building.

**n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

- **embedding_** [array, shape = (n_samples, n_components)] Spectral embedding of the training matrix.
- **affinity_matrix_** [array, shape = (n_samples, n_samples)] Affinity_matrix constructed from samples or precomputed.
- **n_neighbors_** [int] Number of nearest neighbors effectively used.

**References**

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import SpectralEmbedding
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
```
embedding = SpectralEmbedding(n_components=2)
X_transformed = embedding.fit_transform(X[:100])
X_transformed.shape
(100, 2)

Methods

fit(self, X[, y]) Fit the model from data in X.

fit_transform(self, X[, y]) Fit the model from data in X and transform X.

get_params(self[, deep]) Get parameters for this estimator.

set_params(self, **params) Set the parameters of this estimator.

Methods

__init__(self, n_components=2, affinity='nearest_neighbors', gamma=None, random_state=None, eigen_solver=None, n_neighbors=None, n_jobs=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Fit the model from data in X.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

Returns

self [object] Returns the instance itself.

fit_transform (self, X, y=None)
Fit the model from data in X and transform X.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
**set_params** *(self, **params)*  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

  **params** [dict] Estimator parameters.

**Returns**

  self [object] Estimator instance.

Examples using `sklearn.manifold.SpectralEmbedding`

- Various Agglomerative Clustering on a 2D embedding of digits
- Comparison of Manifold Learning methods
- Manifold Learning methods on a severed sphere
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

7.23.5 `sklearn.manifold.TSNE`

class `sklearn.manifold.TSNE` (n_components=2, perplexity=30.0, early_exaggeration=12.0, learning_rate=200.0, n_iter=1000, n_iter_without_progress=300, min_grad_norm=1e-07, metric='euclidean', init='random', verbose=0, random_state=None, method='barnes_hut', angle=0.5, n_jobs=None)

t-distributed Stochastic Neighbor Embedding.

t-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. t-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten’s FAQ [2].

Read more in the User Guide.

**Parameters**

  n_components [int, optional (default: 2)] Dimension of the embedded space.

  perplexity [float, optional (default: 30.0)] The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Different values can result in significantly different results.

  early_exaggeration [float, optional (default: 12.0)] Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.
learning_rate: [float, optional (default: 200.0)] The learning rate for t-SNE is usually in the range [10.0, 1000.0]. If the learning rate is too high, the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum increasing the learning rate may help.

n_iter: [int, optional (default: 1000)] Maximum number of iterations for the optimization. Should be at least 250.

n_iter_without_progress: [int, optional (default: 300)] Maximum number of iterations without progress before we abort the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50.

New in version 0.17: parameter n_iter_without_progress to control stopping criteria.

min_grad_norm: [float, optional (default: 1e-7)] If the gradient norm is below this threshold, the optimization will be stopped.

metric: [string or callable, optional] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them. The default is “euclidean” which is interpreted as squared euclidean distance.

init: [string or numpy array, optional (default: “random”)] Initialization of embedding. Possible options are ‘random’, ‘pca’, and a numpy array of shape (n_samples, n_components). PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization.

verbose: [int, optional (default: 0)] Verbosity level.

random_state: [int, RandomState instance or None, optional (default: None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that different initializations might result in different local minima of the cost function.

method: [string (default: ‘barnes_hut’)] By default the gradient calculation algorithm uses Barnes-Hut approximation running in O(NlogN) time. method='exact' will run on the slower, but exact, algorithm in O(N^2) time. The exact algorithm should be used when nearest-neighbor errors need to be better than 3%. However, the exact method cannot scale to millions of examples.

New in version 0.17: Approximate optimization method via the Barnes-Hut.

angle: [float (default: 0.5)] Only used if method='barnes_hut' This is the trade-off between speed and accuracy for Barnes-Hut T-SNE. ‘angle’ is the angular size (referred to as theta in [3]) of a distant node as measured from a point. If this size is below ‘angle’ then it is used as a summary node of all points contained within it. This method is not very sensitive to changes in this parameter in the range of 0.2 - 0.8. Angle less than 0.2 has quickly increasing computation time and angle greater 0.8 has quickly increasing error.

n_jobs: [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. This parameter has no impact when metric=“precomputed” or (metric=“euclidean” and method=“exact”). None means 1 unless in a...
joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.22.

Attributes

- `embedding_` [array-like, shape (n_samples, n_components)] Stores the embedding vectors.
- `kl_divergence_` [float] Kullback-Leibler divergence after optimization.
- `n_iter_` [int] Number of iterations run.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.manifold import TSNE

>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> X_embedded = TSNE(n_components=2).fit_transform(X)
>>> X_embedded.shape
(4, 2)
```

Methods

- `fit(self, X[, y])` Fit X into an embedded space.
- `fit_transform(self, X[, y])` Fit X into an embedded space and return that transformed output.
- `get_params(self[, deep])` Get parameters for this estimator.
- `set_params(self[, deep], **params)` Set the parameters of this estimator.

```python
__init__(self, n_components=2, perplexity=30.0, early_exaggeration=12.0, learning_rate=200.0, n_iter=1000, n_iter_without_progress=300, min_grad_norm=1e-07, metric='euclidean', init='random', verbose=0, random_state=None, method='barnes_hut', angle=0.5, n_jobs=None)

Initialize self. See help(type(self)) for accurate signature.
```

- `fit(self, X, y=None)` Fit X into an embedded space.

Parameters

- `X` [array, shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘precomputed’ X must be a square distance matrix. Otherwise it contains a sample per row. If the method is ‘exact’, X may be a sparse matrix of type ‘csr’, ‘csc’ or ‘coo’. If the method is ‘barnes_hut’ and the metric is ‘precomputed’, X may be a precomputed sparse graph.
fit_transform(self, X, y=None)
Fit X into an embedded space and return that transformed output.

Parameters

X [array, shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘precomputed’ X must be a square distance matrix. Otherwise it contains a sample per row. If the method is ‘exact’, X may be a sparse matrix of type ‘csr’, ‘csc’ or ‘coo’. If the method is ‘barnes_hut’ and the metric is ‘precomputed’, X may be a precomputed sparse graph.

y [Ignored]

Returns

X_new [array, shape (n_samples, n_components)] Embedding of the training data in low-dimensional space.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Perform a Locally Linear Embedding analysis on the data.

Read more in the User Guide.

**Parameters**

- **X** ([array-like, NearestNeighbors]) Sample data, shape = (n_samples, n_features), in the form of a numpy array or a NearestNeighbors object.
- **n_neighbors** [integer] number of neighbors to consider for each point.
- **n_components** [integer] number of coordinates for the manifold.
- **reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.
- **eigen_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data
  - **arpack** [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.
  - **dense** [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.
- **tol** [float, optional] Tolerance for ‘arpack’ method Not used if eigen_solver==‘dense’.
- **max_iter** [integer] maximum number of iterations for the arpack solver.
- **method** [[‘standard’, ‘hessian’, ‘modified’, ‘ltsa’]]
  - **standard** [use the standard locally linear embedding algorithm.] see reference [1]
  - **hessian** [use the Hessian eigenmap method. This method requires] n_neighbors > n_components * (1 + (n_components + 1) / 2. see reference [2]
  - **modified** [use the modified locally linear embedding algorithm.] see reference [3]
  - **ltsa** [use local tangent space alignment algorithm] see reference [4]
- **hessian_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if method == ‘hessian’
- **modified_tol** [float, optional] Tolerance for modified LLE method. Only used if method == ‘modified’
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘arpack’.
- **n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Returns**
Y [array-like, shape [n_samples, n_components]] Embedding vectors.

squared_error [float] Reconstruction error for the embedding vectors. Equivalent to \( \text{norm}(Y - W Y, 'fro')^2 \), where W are the reconstruction weights.

Examples using sklearn.manifold.locally_linear_embedding

- Swiss Roll reduction with LLE

7.23.7 sklearn.manifold.smacof

sklearn.manifold.smacof(dissimilarities, metric=True, n_components=2, init=None, n_init=8, n_jobs=None, max_iter=300, verbose=0, eps=0.001, random_state=None, return_n_iter=False)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COnplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the stress) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

Parameters

dissimilarities [ndarray, shape (n_samples, n_samples)] Pairwise dissimilarities between the points. Must be symmetric.

metric [boolean, optional, default: True] Compute metric or nonmetric SMACOF algorithm.

n_components [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities. If an init array is provided, this option is overridden and the shape of init is used to determine the dimensionality of the embedding space.

init [ndarray, shape (n_samples, n_components), optional, default: None] Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.

n_init [int, optional, default: 8] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If init is provided, this option is overridden and a single run is performed.
**n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel.

None means 1 unless in a *joblib.parallel_backend* context. -1 means using all processors. See *Glossary* for more details.

**max_iter** [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.

**verbose** [int, optional, default: 0] Level of verbosity.

**eps** [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.

**random_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

**return_n_iter** [bool, optional, default: False] Whether or not to return the number of iterations.

**Returns**

- **X** [ndarray, shape (n_samples, n_components)] Coordinates of the points in a n_components-space.
- **stress** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).
- **n_iter** [int] The number of iterations corresponding to the best stress. Returned only if *return_n_iter* is set to True.

**Notes**

“Nonmetric multidimensional scaling: a numerical method” Kruskal, J. Psychometrika, 29 (1964)

“Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis” Kruskal, J. Psychometrika, 29, (1964)

### 7.23.8 sklearn.manifold.spectral_embedding

**sklearn.manifold.spectral_embedding** *(adjacency, n_components=8, eigen_solver=None, random_state=None, eigen_tol=0.0, norm_laplacian=True, drop_first=True)*

Project the sample on the first eigenvectors of the graph Laplacian.

The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also ‘work’ even if the adjacency variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).

However care must taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.
Note: Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the User Guide.

Parameters

- adjacency [array-like or sparse graph, shape: (n_samples, n_samples)] The adjacency matrix of the graph to embed.

- n_components [integer, optional, default 8] The dimension of the projection subspace.

- eigen_solver [None, ‘arpack’, ‘lobpcg’, or ‘amg’, default None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

- random_state [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigenvectors decomposition. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘amg’.

- eigen_tol [float, optional, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

- norm_laplacian [bool, optional, default=True] If True, then compute normalized Laplacian.

- drop_first [bool, optional, default=True] Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

Returns

- embedding [array, shape=(n_samples, n_components)] The reduced samples.

Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there graph has many components, the first few eigenvectors will simply uncover the connected components of the graph.

7.23.9 sklearn.manifold.trustworthiness

sklearn.manifold.trustworthiness (X, X_embedded, n_neighbors=5, metric='euclidean')

Expresses to what extent the local structure is retained.

The trustworthiness is within [0, 1]. It is defined as

\[ T(k) = 1 - \frac{2}{nk(2n - 3k - 1)} \sum_{i=1}^{n} \sum_{j \in N_i^k} \max(0, (r(i, j) - k)) \]
where for each sample $i$, $\mathcal{N}^k_i$ are its $k$ nearest neighbors in the output space, and every sample $j$ is its $r(i, j)$-th nearest neighbor in the input space. In other words, any unexpected nearest neighbors in the output space are penalised in proportion to their rank in the input space.

- “Neighborhood Preservation in Nonlinear Projection Methods: An Experimental Study” J. Venna, S. Kaski
- “Learning a Parametric Embedding by Preserving Local Structure” L.J.P. van der Maaten

**Parameters**

- $X$ [array, shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘precomputed’ $X$ must be a square distance matrix. Otherwise it contains a sample per row.
- $X_{\text{embedded}}$ [array, shape (n_samples, n_components)] Embedding of the training data in low-dimensional space.
- $n_{\text{neighbors}}$ [int, optional (default: 5)] Number of neighbors $k$ that will be considered.
- $\text{metric}$ [string, or callable, optional, default ‘euclidean’] Which metric to use for computing pairwise distances between samples from the original input space. If metric is ‘precomputed’, $X$ must be a matrix of pairwise distances or squared distances. Otherwise, see the documentation of argument metric in sklearn.pairwise.pairwise_distances for a list of available metrics.

**Returns**

- $\text{trustworthiness}$ [float] Trustworthiness of the low-dimensional embedding.

### 7.24 sklearn.metrics: Metrics

See the Metrics and scoring: quantifying the quality of predictions section and the Pairwise metrics, Affinities and Kernels section of the user guide for further details.

The sklearn.metrics module includes score functions, performance metrics and pairwise metrics and distance computations.

#### 7.24.1 Model Selection Interface

See the The scoring parameter: defining model evaluation rules section of the user guide for further details.

```python
textmetrics.check_scoring(estimator[, scoring, ...])
metrics.get_scorer(scoring)
metrics.make_scorer(score_func[,...])
```

**sklearn.metrics.check_scoring**

sklearn.metrics.check_scoring(estimator, scoring=None, allow_none=False)

Determine scorer from user options.

A TypeError will be thrown if the estimator cannot be scored.

**Parameters**

- $\text{estimator}$ [estimator object implementing ‘fit’] The object to use to fit the data.
scoring [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

allow_none [boolean, optional, default: False] If no scoring is specified and the estimator has no score function, we can either return None or raise an exception.

Returns
scoring [callable] A scorer callable object / function with signature scorer(estimator, X, y).

sklearn.metrics.get_scorer

sklearn.metrics.get_scorer(scoring)
Get a scorer from string.
Read more in the User Guide.

Parameters
scoring [str | callable] scoring method as string. If callable it is returned as is.

Returns
scorer [callable] The scorer.

sklearn.metrics.make_scorer

sklearn.metrics.make_scorer(score_func, greater_is_better=True, needs_proba=False, needs_threshold=False, **kwargs)
Make a scorer from a performance metric or loss function.
This factory function wraps scoring functions for use in GridSearchCV and cross_val_score. It takes a score function, such as accuracy_score, mean_squared_error, adjusted_rand_index or average_precision and returns a callable that scores an estimator’s output.
Read more in the User Guide.

Parameters
score_func [callable.] Score function (or loss function) with signature score_func(y, y_pred, **kwargs).

greater_is_better [boolean, default=True] Whether score_func is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the score_func.

needs_proba [boolean, default=False] Whether score_func requires predict_proba to get probability estimates out of a classifier.
If True, for binary y_true, the score function is supposed to accept a 1D y_pred (i.e., probability of the positive class, shape (n_samples,)).

needs_threshold [boolean, default=False] Whether score_func takes a continuous decision certainty. This only works for binary classification using estimators that have either a decision_function or predict_proba method.
If True, for binary y_true, the score function is supposed to accept a 1D y_pred (i.e., probability of the positive class or the decision function, shape (n_samples,)).
For example `average_precision` or the area under the roc curve can not be computed using discrete predictions alone.

**kwargs [additional arguments] Additional parameters to be passed to score_func.

Returns

scorer [callable] Callable object that returns a scalar score; greater is better.

Notes

If `needs_proba=False` and `needs_threshold=False`, the score function is supposed to accept the output of `predict`. If `needs_proba=True`, the score function is supposed to accept the output of `predict_proba` (For binary `y_true`, the score function is supposed to accept probability of the positive class). If `needs_threshold=True`, the score function is supposed to accept the output of `decision_function`.

Examples

```python
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},...
        scoring=ftwo_scorer)
```

Examples using `sklearn.metrics.make_scorer`

- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

7.24.2 Classification metrics

See the Classification metrics section of the user guide for further details.

```python
metrics.accuracy_score(y_true, y_pred[, ...]) Accuracy classification score.
multiclass.auc(x, y) Compute Area Under the Curve (AUC) using the trapezoidal rule
metrics.average_precision_score(y_true, y_score) Compute average precision (AP) from prediction scores
metrics.balanced_accuracy_score(y_true, y_pred) Compute the balanced accuracy
metrics.brier_score_loss(y_true, y_prob[, ...]) Compute the Brier score.
multiclass.classification_report(y_true, y_pred) Build a text report showing the main classification metrics
metrics.cohen_kappa_score(y1, y2[, labels, ...]) Cohen’s kappa: a statistic that measures inter-annotator agreement.
multiclass.confusion_matrix(y_true, y_pred[, ...]) Compute confusion matrix to evaluate the accuracy of a classification.
```
metrics.dcg_score(y_true, y_score[, k, ...]) Compute Discounted Cumulative Gain.
metrics.f1_score(y_true, y_pred[, labels, ...]) Compute the F1 score, also known as balanced F-score or F-measure.
metrics.fbeta_score(y_true, y_pred, beta[, ...]) Compute the F-beta score.
metrics.hamming_loss(y_true, y_pred[, ...]) Compute the average Hamming loss.
metrics.hinge_loss(y_true, pred_decision[, ...]) Compute average hinge loss (non-regularized).
metrics.jaccard_score(y_true, y_pred[, ...]) Jaccard similarity coefficient score.
metrics.log_loss(y_true, y_pred[, eps, ...]) Compute log loss, aka logistic loss or cross-entropy loss.
metrics.matthews_corrcoef(y_true, y_pred[, ...]) Compute the Matthews correlation coefficient (MCC).
metrics.multilabel_confusion_matrix(y_true[, ...]) Compute a confusion matrix for each class or sample.
metrics.ndcg_score(y_true, y_score[, k, ...]) Compute Normalized Discounted Cumulative Gain.
metrics.precision_recall_curve(y_true[, ...]) Compute precision-recall pairs for different probability thresholds.
metrics.precision_recall_fscore_support(y_true, y_pred[, ...]) Compute precision, recall, F-measure and support for each class.
metrics.precision_score(y_true, y_pred[, ...]) Compute the precision.
metrics.recall_score(y_true, y_pred[, ...]) Compute the recall.
metrics.roc_auc_score(y_true, y_score[, ...]) Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.
metrics.roc_curve(y_true, y_score[, ...]) Compute Receiver operating characteristic (ROC).
metrics.zero_one_loss(y_true, y_pred[, ...]) Zero-one classification loss.

sklearn.metrics.accuracy_score

sklearn.metrics.accuracy_score(y_true, y_pred, normalize=True, sample_weight=None) Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must exactly match the corresponding set of labels in y_true.

Read more in the User Guide.

Parameters

y_true [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

y_pred [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

normalize [bool, optional (default=True)] If False, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] If normalize == True, return the fraction of correctly classified samples (float), else returns the number of correctly classified samples (int). The best performance is 1 with normalize == True and the number of samples with normalize == False.
See also:

\textit{jaccard\_score}, \textit{hamming\_loss}, \textit{zero\_one\_loss}

Notes

In binary and multiclass classification, this function is equal to the jaccard\_score function.

Examples

```python
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

Examples using \texttt{sklearn.metrics.accuracy\_score}

- \texttt{Plot classification probability}
- \texttt{Multi-class AdaBoosted Decision Trees}
- \texttt{Probabilistic predictions with Gaussian process classification (GPC)}
- \texttt{Demonstration of multi-metric evaluation on cross\_val\_score and GridSearchCV}
- \texttt{Importance of Feature Scaling}
- \texttt{Classification of text documents using sparse features}

\texttt{sklearn.metrics.auc}

\texttt{sklearn.metrics.auc(x, y)}

Compute Area Under the Curve (AUC) using the trapezoidal rule

This is a general function, given points on a curve. For computing the area under the ROC-curve, see \texttt{roc\_auc\_score}. For an alternative way to summarize a precision-recall curve, see \texttt{average\_precision\_score}.

Parameters

- \texttt{x} [array, shape = [n]] x coordinates. These must be either monotonic increasing or monotonic decreasing.
- \texttt{y} [array, shape = [n]] y coordinates.

Returns

- \texttt{auc} [float]
See also:

- **roc_auc_score** Compute the area under the ROC curve
- **average_precision_score** Compute average precision from prediction scores
- **precision_recall_curve** Compute precision-recall pairs for different probability thresholds

**Examples**

```python
>>> import numpy as np
>>> from sklearn import metrics

>>> y = np.array([1, 1, 2, 2])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
>>> metrics.auc(fpr, tpr)
0.75
```

**Examples using sklearn.metrics.auc**

- Species distribution modeling
- Receiver Operating Characteristic (ROC) with cross validation
- Receiver Operating Characteristic (ROC)
- Precision-Recall

**sklearn.metrics.average_precision_score**

`sklearn.metrics.average_precision_score(y_true, y_score, average='macro', pos_label=1, sample_weight=None)`

Compute average precision (AP) from prediction scores

AP summarizes a precision-recall curve as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

\[
AP = \sum_n (R_n - R_{n-1})P_n
\]

where \(P_n\) and \(R_n\) are the precision and recall at the nth threshold \[1\]. This implementation is not interpolated and is different from computing the area under the precision-recall curve with the trapezoidal rule, which uses linear interpolation and can be too optimistic.

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the *User Guide*.

**Parameters**

- **y_true** [array, shape = [n_samples] or [n_samples, n_classes]] True binary labels or binary label indicators.
- **y_score** [array, shape = [n_samples] or [n_samples, n_classes]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
average [string, [None, ‘micro’, ‘macro’ (default), ‘samples’, ‘weighted’]] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'micro': Calculate metrics globally by considering each element of the label indicator matrix as a label.
'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).
'samples': Calculate metrics for each instance, and find their average.
Will be ignored when y_true is binary.
pos_label [int or str (default=1)] The label of the positive class. Only applied to binary y_true. For multilabel-indicator y_true, pos_label is fixed to 1.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

average_precision [float]

See also:

roc_auc_score Compute the area under the ROC curve
precision_recall_curve Compute precision-recall pairs for different probability thresholds

Notes

Changed in version 0.19: Instead of linearly interpolating between operating points, precisions are weighted by the change in recall since the last operating point.

References

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```

Examples using sklearn.metrics.average_precision_score

- Precision-Recall
sklearn.metrics.balanced_accuracy_score

sklearn.metrics.balanced_accuracy_score(y_true, y_pred, sample_weight=None, adjusted=False)

Compute the balanced accuracy

The balanced accuracy in binary and multiclass classification problems to deal with imbalanced datasets. It is defined as the average of recall obtained on each class.

The best value is 1 and the worst value is 0 when adjusted=False.

Read more in the User Guide.

Parameters

- y_true [1d array-like] Ground truth (correct) target values.
- y_pred [1d array-like] Estimated targets as returned by a classifier.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.
- adjusted [bool, default=False] When true, the result is adjusted for chance, so that random performance would score 0, and perfect performance scores 1.

Returns

- balanced_accuracy [float]

See also:

recall_score, roc_auc_score

Notes

Some literature promotes alternative definitions of balanced accuracy. Our definition is equivalent to accuracy_score with class-balanced sample weights, and shares desirable properties with the binary case. See the User Guide.

References

[1], [2]

Examples

```python
>>> from sklearn.metrics import balanced_accuracy_score
>>> y_true = [0, 1, 0, 0, 1, 0]
>>> y_pred = [0, 1, 0, 0, 0, 1]
>>> balanced_accuracy_score(y_true, y_pred)
0.625
```

sklearn.metrics.brier_score_loss

sklearn.metrics.brier_score_loss(y_true, y_prob, sample_weight=None, pos_label=None)

Compute the Brier score. The smaller the Brier score, the better, hence the naming with “loss”. Across all items in a set N predictions, the Brier score measures the mean squared difference between (1) the predicted probability assigned to the possible outcomes for item i, and (2) the actual outcome. Therefore, the lower
the Brier score is for a set of predictions, the better the predictions are calibrated. Note that the Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1). The Brier loss is composed of refinement loss and calibration loss. The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another). Which label is considered to be the positive label is controlled via the parameter pos_label, which defaults to 1. Read more in the User Guide.

Parameters

- `y_true` [array, shape (n_samples,)] True targets.
- `y_prob` [array, shape (n_samples,)] Probabilities of the positive class.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `pos_label` [int or str, default=None] Label of the positive class. Defaults to the greater label unless y_true is all 0 or all -1 in which case pos_label defaults to 1.

Returns

- `score` [float] Brier score

References

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true_categorical, y_prob, pos_label="ham")
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.0
```

Examples using `sklearn.metrics.brier_score_loss`

- Probability Calibration curves
- Probability calibration of classifiers

`sklearn.metrics.classification_report`

`sklearn.metrics.classification_report` *(y_true, y_pred, labels=None, target_names=None, sample_weight=None, digits=2, output_dict=False, zero_division='warn')*

Build a text report showing the main classification metrics
Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels** [array, shape = [n_labels]] Optional list of label indices to include in the report.
- **target_names** [list of strings] Optional display names matching the labels (same order).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **digits** [int] Number of digits for formatting output floating point values. When output_dict is True, this will be ignored and the returned values will not be rounded.
- **output_dict** [bool (default = False)] If True, return output as dict
- **zero_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

Returns

- **report** [string / dict] Text summary of the precision, recall, F1 score for each class. Dictionary returned if output_dict is True. Dictionary has the following structure:

```python
{'label 1': {'precision':0.5, 'recall':1.0, 'f1-score':0.67, 'support':1},
 'label 2': { ... }, ...
}
```

The reported averages include macro average (averaging the unweighted mean per label), weighted average (averaging the support-weighted mean per label), and sample average (only for multilabel classification). Micro average (averaging the total true positives, false negatives and false positives) is only shown for multi-label or multi-class with a subset of classes, because it corresponds to accuracy otherwise. See also precision_recall_fscore_support for more details on averages.

Note that in binary classification, recall of the positive class is also known as “sensitivity”; recall of the negative class is “specificity”.

See also:

- precision_recall_fscore_support
- confusion_matrix
- multilabel_confusion_matrix

Examples

```python
>>> from sklearn.metrics import classification_report
>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']
>>> print(classification_report(y_true, y_pred, target_names=target_names))
```

(continues on next page)
### Examples using sklearn.metrics.classification_report

- Recognizing hand-written digits
- Faces recognition example using eigenfaces and SVMs
- Pipeline Anova SVM
- Parameter estimation using grid search with cross-validation

- Label Propagation digits active learning
- Classification of text documents using sparse features

**sklearn.metrics.cohen_kappa_score**

`sklearn.metrics.cohen_kappa_score(y1, y2, labels=None, weights=None, sample_weight=None)`

Cohen’s kappa: a statistic that measures inter-annotator agreement. This function computes Cohen’s kappa [1], a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

\[ \kappa = \frac{p_o - p_e}{1 - p_e} \]

where \( p_o \) is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and \( p_e \) is the expected agreement when both annotators assign labels randomly. \( p_e \) is estimated using a per-annotator empirical prior over the class labels [2].

---

---
Read more in the User Guide.

Parameters

- **y1** [array, shape = [n_samples]] Labels assigned by the first annotator.
- **y2** [array, shape = [n_samples]] Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping `y1` and `y2` doesn’t change the value.
- **labels** [array, shape = [n_classes], optional] List of labels to index the matrix. This may be used to select a subset of labels. If `None`, all labels that appear at least once in `y1` or `y2` are used.
- **weights** [str, optional] Weighting type to calculate the score. None means no weighted; “linear” means linear weighted; “quadratic” means quadratic weighted.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **kappa** [float] The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

References

[1], [2], [3]

sklearn.metrics.confusion_matrix

`sklearn.metrics.confusion_matrix(y_true, y_pred, labels=None, sample_weight=None, normalize=None)`

Compute confusion matrix to evaluate the accuracy of a classification.

By definition a confusion matrix $C$ is such that $C_{i,j}$ is equal to the number of observations known to be in group $i$ and predicted to be in group $j$.

Thus in binary classification, the count of true negatives is $C_{0,0}$, false negatives is $C_{1,0}$, true positives is $C_{1,1}$ and false positives is $C_{0,1}$.

Read more in the User Guide.

Parameters

- **y_true** [array-like of shape (n_samples,)] Ground truth (correct) target values.
- **y_pred** [array-like of shape (n_samples,)] Estimated targets as returned by a classifier.
- **labels** [array-like of shape (n_classes), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If `None` is given, those that appear at least once in `y_true` or `y_pred` are used in sorted order.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **normalize** [{'true', 'pred', 'all'}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.

Returns

- **C** [ndarray of shape (n_classes, n_classes)] Confusion matrix.
References
[1]

Examples

```python
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])

>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> confusion_matrix(y_true, y_pred, labels=["ant", "bird", "cat"])
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

In the binary case, we can extract true positives, etc as follows:

```python
>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)
```

Examples using `sklearn.metrics.confusion_matrix`

- Faces recognition example using eigenfaces and SVMs
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
- Classification of text documents using sparse features

`sklearn.metrics.dcg_score`:

`sklearn.metrics.dcg_score(y_true, y_score, k=None, log_base=2, sample_weight=None, ignore_ties=False)`

Compute Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. This ranking metric yields a high value if true labels are ranked high by `y_score`. Usually the Normalized Discounted Cumulative Gain (NDCG, computed by `ndcg_score`) is preferred.

**Parameters**

- `y_true` [ndarray, shape (n_samples, n_labels)] True targets of multilabel classification, or true scores of entities to be ranked.
- `y_score` [ndarray, shape (n_samples, n_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
k [int, optional (default=None)] Only consider the highest k scores in the ranking. If None, use all outputs.

log_base [float, optional (default=2)] Base of the logarithm used for the discount. A low value means a sharper discount (top results are more important).

sample_weight [ndarray, shape (n_samples,), optional (default=None)] Sample weights. If None, all samples are given the same weight.

ignore_ties [bool, optional (default=False)] Assume that there are no ties in y_score (which is likely to be the case if y_score is continuous) for efficiency gains.

Returns

discounted_cumulative_gain [float] The averaged sample DCG scores.

See also:

ndcg_score The Discounted Cumulative Gain divided by the Ideal Discounted Cumulative Gain (the DCG obtained for a perfect ranking), in order to have a score between 0 and 1.

References

Wikipedia entry for Discounted Cumulative Gain

Examples

```python
>>> from sklearn.metrics import dcg_score
>>> # we have groud-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict scores for the answers
>>> scores = np.asarray([[.1, .2, .3, 4, 70]])
>>> dcg_score(true_relevance, scores) # doctest: +ELLIPSIS
9.49...

>>> # we can set k to truncate the sum; only top k answers contribute
>>> dcg_score(true_relevance, scores, k=2) # doctest: +ELLIPSIS
5.63...

>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average true
>>> # relevance of our top predictions: (10 + 5) / 2 = 7.5
>>> dcg_score(true_relevance, scores, k=1) # doctest: +ELLIPSIS
7.5

>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
>>> # wrong results:
>>> dcg_score(true_relevance,
```

(continues on next page)
.. code-block:: python

    

    scores, k=1, ignore_ties=True) # doctest: +ELLIPSIS

5.0

sklearn.metrics.f1_score

`sklearn.metrics.f1_score(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Compute the F1 score, also known as balanced F-score or F-measure

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

\[
F1 = \frac{2 \times (precision \times recall)}{(precision + recall)}
\]

In the multi-class and multi-label case, this is the average of the F1 score of each class with weighting depending on the `average` parameter.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

  Changed in version 0.17: parameter `labels` improved for multiclass problem.
- **pos_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- **average** [string, [None, 'binary'] (default), ‘micro’, ‘macro’, ‘samples’, ‘weighted’)] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

  - `binary`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.
  - `micro`: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - `macro`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `weighted`: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

**sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights.

**zero_division**  ['warn', 0 or 1, default='warn'] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to “warn”, this acts as 0, but warnings are also raised.

**Returns**

**f1_score**  [float or array of float, shape = [n_unique_labels]] F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

See also:

* fbeta_score, precision_recall_fscore_support, jaccard_score
* multilabel_confusion_matrix

**Notes**

When true positive + false positive == 0, precision is undefined; When true positive + false negative == 0, recall is undefined. In such cases, by default the metric will be set to 0, as will f-score, and UndefinedMetricWarning will be raised. This behavior can be modified with zero_division.

**Examples**

```python
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([0.8, 0., 0. ])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> f1_score(y_true, y_pred, zero_division=1)
1.0...
```

**Examples using sklearn.metrics.f1_score**

- Probability Calibration curves
- Precision-Recall
**sklearn.metrics.fbeta_score**

**sklearn.metrics.fbeta_score** *(y_true, y_pred, beta, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')*

Compute the F-beta score

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The `beta` parameter determines the weight of recall in the combined score. `beta < 1` lends more weight to precision, while `beta > 1` favors recall (`beta -> 0` considers only precision, `beta -> +inf` only recall).

Read more in the *User Guide*.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **beta** [float] Determines the weight of recall in the combined score.
- **labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order. Changed in version 0.17: parameter `labels` improved for multiclass problem.
- **pos_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- **average** [string, [None, ‘binary’ (default), ‘micro’, ‘macro’, ‘samples’, ‘weighted’]] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - `'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.
  - `'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - `'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `'weighted'`: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters `macro` to account for label imbalance; it can result in an F-score that is not between precision and recall.
  - `'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **zero_division** [“warn”, 0 or 1, default=”warn”] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to “warn”, this acts as 0, but warnings are also raised.
Returns

**fbeta_score** [float (if average is not None) or array of float, shape = [n_unique_labels]] F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

See also:

**precision_recall_fscore_support, multilabel_confusion_matrix**

Notes

When true positive + false positive == 0 or true positive + false negative == 0, f-score returns 0 and raises UndefinedMetricWarning. This behavior can be modified with zero_division.

array([0.71..., 0. , 0. ])
```

**sklearn.metrics.hamming_loss**

**sklearn.metrics.hamming_loss** *(y_true, y_pred, labels=None, sample_weight=None)*

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **labels** [array, shape = [n_labels], optional (default='deprecated')] Integer array of labels. If not provided, labels will be inferred from y_true and y_pred.

    New in version 0.18.
Deprecated since version 0.21: This parameter labels is deprecated in version 0.21 and will be removed in version 0.23. Hamming loss uses `y_true.shape[1]` for the number of labels when `y_true` is binary label indicators, so it is unnecessary for the user to specify.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

New in version 0.18.

**Returns**

**loss** [float or int.] Return the average Hamming loss between element of \(y_{true}\) and \(y_{pred}\).

See also:

`accuracy_score`, `jaccard_score`, `zero_one_loss`

**Notes**

In multiclass classification, the Hamming loss corresponds to the Hamming distance between \(y_{true}\) and \(y_{pred}\) which is equivalent to the subset `zero_one_loss` function, when `normalize` parameter is set to True.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does not entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes only the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss, when `normalize` parameter is set to True. It is always between 0 and 1, lower being better.

**References**

[1], [2]

**Examples**

```python
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

**Examples using sklearn.metrics.hamming_loss**

- `Model Complexity Influence`
**sklearn.metrics.hinge_loss**

sklearn.metrics.hinge_loss(y_true, pred_decision, labels=None, sample_weight=None)

Average hinge loss (non-regularized)

In binary class case, assuming labels in y_true are encoded with +1 and -1, when a prediction mistake is made, margin = y_true * pred_decision is always negative (since the signs disagree), implying 1 - margin is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.

In multiclass case, the function expects that either all the labels are included in y_true or an optional labels argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer’s method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the *User Guide*.

**Parameters**

- **y_true** [array, shape = [n_samples]] True target, consisting of integers of two values. The positive label must be greater than the negative label.
- **pred_decision** [array, shape = [n_samples] or [n_samples, n_classes]] Predicted decisions, as output by decision_function (floats).
- **labels** [array, optional, default None] Contains all the labels for the problem. Used in multiclass hinge loss.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **loss** [float]

**References**

[1], [2], [3]

**Examples**

```python
>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss
>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(random_state=0)
>>> pred_decision = est.decision_function([-2], [3], [0.5])
>>> pred_decision
array([-2.18..., 2.36..., 0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...
```

In the multiclass case:

```python
>>> import numpy as np
>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
```
```python
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC()
>>> pred_decision = est.decision_function([[-1], [2], [3]])
>>> y_true = [0, 2, 3]
>>> hinge_loss(y_true, pred_decision, labels)
0.56...
```

### sklearn.metrics.jaccard_score

**sklearn.metrics.jaccard_score** *(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None)*

Jaccard similarity coefficient score

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in `y_true`.

Read more in the *User Guide*.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **labels** [list, optional] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
- **pos_label** [str or int, 1 by default] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.
- **average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - 'binary': Only report results for the class specified by pos_label. This is applicable only if targets (y_{true,pred}) are binary.
  - 'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - 'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance.
  - 'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification).
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float (if average is not None) or array of floats, shape = [n_unique_labels]]

See also:

accuracy_score, f_score, multilabel_confusion_matrix

Notes

jaccard_score may be a poor metric if there are no positives for some samples or classes. Jaccard is undefined if there are no true or predicted labels, and our implementation will return a score of 0 with a warning.

References

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import jaccard_score
>>> y_true = np.array([[0, 1, 1],
...                     [1, 1, 0]])
>>> y_pred = np.array([[1, 1, 1],
...                     [1, 0, 0]])

In the binary case:

>>> jaccard_score(y_true[0], y_pred[0])
0.6666...

In the multilabel case:

>>> jaccard_score(y_true, y_pred, average='samples')
0.5833...
>>> jaccard_score(y_true, y_pred, average='macro')
0.6666...
>>> jaccard_score(y_true, y_pred, average=None)
array([0.5, 0.5, 1.])

In the multiclass case:

>>> y_pred = [0, 2, 1, 2]
>>> y_true = [0, 1, 2, 2]
>>> jaccard_score(y_true, y_pred, average=None)
array([0. , 0. , 0.33...])
```

Examples using sklearn.metrics.jaccard_score

- Classifier Chain
sklearn.metrics.log_loss

sklearn.metrics.log_loss(y_true, y_pred, eps=1e-15, normalize=True, sample_weight=None, labels=None)

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of the true labels given a probabilistic classifier’s predictions. The log loss is only defined for two or more labels. For a single sample with true label yt in \{0,1\} and estimated probability yp that yt = 1, the log loss is

\[-\log P(yt|yp) = -(yt \log(yp) + (1 - yt) \log(1 - yp))\]

Read more in the User Guide.

Parameters

- `y_true` [array-like or label indicator matrix] Ground truth (correct) labels for n_samples samples.
- `y_pred` [array-like of float, shape = (n_samples, n_classes) or (n_samples,)] Predicted probabilities, as returned by a classifier’s predict_proba method. If `y_pred.shape = (n_samples,)` the probabilities provided are assumed to be that of the positive class. The labels in `y_pred` are assumed to be ordered alphabetically, as done by preprocessing.LabelBinarizer.
- `eps` [float] Log loss is undefined for p=0 or p=1, so probabilities are clipped to max(eps, min(1 - eps, p)).
- `normalize` [bool, optional (default=True)] If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `labels` [array-like, optional (default=None)] If not provided, labels will be inferred from `y_true`. If `labels` is None and `y_pred` has shape (n_samples,) the labels are assumed to be binary and are inferred from `y_true`. .. versionadded:: 0.18

Returns

- `loss` [float]

Notes

The logarithm used is the natural logarithm (base-e).

>>> from sklearn.metrics import log_loss
>>> log_loss(["spam", "ham", "ham", "spam"],
... [ [.1, .9], [.9, .1], [.8, .2], [.35, .65]])
0.21616...
```
Examples using `sklearn.metrics.log_loss`

- Probability Calibration for 3-class classification
- Probabilistic predictions with Gaussian process classification (GPC)

`sklearn.metrics.matthews_corrcoef`

`sklearn.metrics.matthews_corrcoef(y_true, y_pred, sample_weight=None)`

Compute the Matthews correlation coefficient (MCC)

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary and multiclass classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]

Binary and multiclass labels are supported. Only in the binary case does this relate to information about true and false positives and negatives. See references below.

Read more in the User Guide.

Parameters

- `y_true` [array, shape = [n_samples]] Ground truth (correct) target values.
- `y_pred` [array, shape = [n_samples]] Estimated targets as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- `mcc` [float] The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an average random prediction and -1 and inverse prediction).

References

[1], [2], [3], [4]

Examples

```python
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

`sklearn.metrics.multilabel_confusion_matrix`

`sklearn.metrics.multilabel_confusion_matrix(y_true, y_pred, sample_weight=None, labels=None, samplewise=False)`

Compute a confusion matrix for each class or sample

New in version 0.21.
Compute class-wise (default) or sample-wise (samplewise=True) multilabel confusion matrix to evaluate the accuracy of a classification, and output confusion matrices for each class or sample.

In multilabel confusion matrix $MCM$, the count of true negatives is $MCM_{0,0}$, false negatives is $MCM_{1,0}$, true positives is $MCM_{1,1}$ and false positives is $MCM_{0,1}$.

Multiclass data will be treated as if binarized under a one-vs-rest transformation. Returned confusion matrices will be in the order of sorted unique labels in the union of (y_true, y_pred).

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] of shape (n_samples, n_outputs) or (n_samples,) Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] of shape (n_samples, n_outputs) or (n_samples,) Estimated targets as returned by a classifier
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights
- **labels** [array-like] A list of classes or column indices to select some (or to force inclusion of classes absent from the data)
- **samplewise** [bool, default=False] In the multilabel case, this calculates a confusion matrix per sample

Returns

- **multi_confusion** [array, shape (n_outputs, 2, 2)] A 2x2 confusion matrix corresponding to each output in the input. When calculating class-wise multi_confusion (default), then n_outputs = n_labels; when calculating sample-wise multi_confusion (samplewise=True), n_outputs = n_samples. If labels is defined, the results will be returned in the order specified in labels, otherwise the results will be returned in sorted order by default.

See also:

- confusion_matrix

Notes

The multilabel_confusion_matrix calculates class-wise or sample-wise multilabel confusion matrices, and in multiclass tasks, labels are binarized under a one-vs-rest way; while confusion_matrix calculates one confusion matrix for confusion between every two classes.

Examples

Multilabel-indicator case:

```python
>>> import numpy as np
>>> from sklearn.metrics import multilabel_confusion_matrix
>>> y_true = np.array([[1, 0, 1],
...                    [0, 1, 0]])
>>> y_pred = np.array([[1, 0, 0],
...                    [0, 1, 1]])
>>> multilabel_confusion_matrix(y_true, y_pred)
array([[1, 0],
       [0, 1]],
       <BLANKLINE> (continues on next page)```
Multiclass case:

```python
>>> y_true = ['cat', 'ant', 'cat', 'cat', 'ant', 'bird']
>>> y_pred = ['ant', 'ant', 'cat', 'cat', 'ant', 'cat']
>>> multilabel_confusion_matrix(y_true, y_pred,
...                            labels=['ant', 'bird', 'cat'])
array([[3, 1],
       [0, 2],
       [2, 1],
       [1, 2]]))
```

**sklearn.metrics.ndcg_score**

`sklearn.metrics.ndcg_score (y_true, y_score, k=None, sample_weight=None, ignore_ties=False)`

Compute Normalized Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. Then divide by the best possible score (Ideal DCG, obtained for a perfect ranking) to obtain a score between 0 and 1.

This ranking metric yields a high value if true labels are ranked high by `y_score`.

**Parameters**

- **y_true** [ndarray, shape (n_samples, n_labels)] True targets of multilabel classification, or true scores of entities to be ranked.
- **y_score** [ndarray, shape (n_samples, n_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **k** [int, optional (default=None)] Only consider the highest k scores in the ranking. If None, use all outputs.
- **sample_weight** [ndarray, shape (n_samples,), optional (default=None)] Sample weights. If None, all samples are given the same weight.
- **ignore_ties** [bool, optional (default=False)] Assume that there are no ties in `y_score` (which is likely to be the case if `y_score` is continuous) for efficiency gains.

**Returns**

- **normalized_discounted_cumulative_gain** [float in [0., 1.]] The averaged NDCG scores for all samples.

**See also:**

- **dcg_score** Discounted Cumulative Gain (not normalized).
References

Wikipedia entry for Discounted Cumulative Gain

Examples

```python
>>> from sklearn.metrics import ndcg_score
>>> # we have ground-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict some scores (relevance) for the answers
>>> scores = np.asarray([[.1, .2, .3, 4, 70]])
>>> ndcg_score(true_relevance, scores) # doctest: +ELLIPSIS
0.69...
>>> scores = np.asarray([ [.05, 1.1, 1., .5, .0]])
>>> ndcg_score(true_relevance, scores) # doctest: +ELLIPSIS
0.49...
>>> # we can set k to truncate the sum; only top k answers contribute.
>>> ndcg_score(true_relevance, scores, k=4) # doctest: +ELLIPSIS
0.35...
>>> # the normalization takes k into account so a perfect answer
>>> # would still get 1.0
>>> ndcg_score(true_relevance, true_relevance, k=4) # doctest: +ELLIPSIS
1.0
>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average (normalized)
>>> # true relevance of our top predictions: (10 / 10 + 5 / 10) / 2 = .75
>>> ndcg_score(true_relevance, scores, k=1) # doctest: +ELLIPSIS
0.75
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
>>> # wrong results:
>>> ndcg_score(true_relevance,
...             scores, k=1, ignore_ties=True) # doctest: +ELLIPSIS
0.5
```

sklearn.metrics.precision_recall_curve

sklearn.metrics.precision_recall_curve(y_true, probas_pred, pos_label=None, sample_weight=None)

Compute precision-recall pairs for different probability thresholds

Note: this implementation is restricted to the binary classification task.

The precision is the ratio $tp / (tp + fp)$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.
The recall is the ratio $\frac{tp}{tp + fn}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the y axis.

Read more in the User Guide.

Parameters

- **y_true** [array, shape = [n_samples]] True binary labels. If labels are not either {-1, 1} or {0, 1}, then pos_label should be explicitly given.
- **probas_pred** [array, shape = [n_samples]] Estimated probabilities or decision function.
- **pos_label** [int or str, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **precision** [array, shape = [n_thresholds + 1]] Precision values such that element i is the precision of predictions with score $\geq$ thresholds[i] and the last element is 1.
- **recall** [array, shape = [n_thresholds + 1]] Decreasing recall values such that element i is the recall of predictions with score $\geq$ thresholds[i] and the last element is 0.
- **thresholds** [array, shape = [n_thresholds <= len(np.unique(probas_pred))]] Increasing thresholds on the decision function used to compute precision and recall.

See also:

- **average_precision_score** Compute average precision from prediction scores
- **roc_curve** Compute Receiver operating characteristic (ROC) curve

Examples

```python
>>> from sklearn.metrics import precision_recall_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> precision, recall, thresholds = precision_recall_curve(y_true, y_scores)
>>> precision
array([0.66666667, 0.5, 1., 1.])
>>> recall
array([1., 0.5, 0.5, 0.])
>>> thresholds
array([0.35, 0.4 , 0.8 ])
```

Examples using sklearn.metrics.precision_recall_curve

- **Precision-Recall**
Compute precision, recall, F-measure and support for each class.

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio $\frac{tp}{tp + fn}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of $\beta$. $\beta = 1.0$ means recall and precision are equally important.

The support is the number of occurrences of each class in $y_{true}$.

If pos_label is None and in binary classification, this function returns the average precision, recall and F-measure if average is one of 'micro', 'macro', 'weighted' or 'samples'.

Read more in the User Guide.

**Parameters**

- **y_true**  [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred**  [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **beta**  [float, 1.0 by default] The strength of recall versus precision in the F-score.
- **labels**  [list, optional] The set of labels to include when average is 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multic和平 class average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in y_true and y_pred are used in sorted order.
- **pos_label**  [str or int, 1 by default] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.
- **average**  [string, [None (default), 'binary', 'micro', 'macro', 'samples', 'weighted')] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - 'binary': Only report results for the class specified by pos_label. This is applicable only if targets (y_true, y_pred) are binary.
  - 'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
'weighted': Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

warn_for [tuple or set, for internal use] This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

zero_division ['warn', 0 or 1, default='warn']

Sets the value to return when there is a zero division:

- recall: when there are no positive labels
- precision: when there are no positive predictions
- f-score: both

If set to “warn”, this acts as 0, but warnings are also raised.

Returns

precision [float (if average is not None) or array of float, shape = [n_unique_labels]]

recall [float (if average is not None) or array of float, , shape = [n_unique_labels]]

fbeta_score [float (if average is not None) or array of float, shape = [n_unique_labels]]

support [None (if average is not None) or array of int, shape = [n_unique_labels]] The number of occurrences of each label in y_true.

Notes

When true positive + false positive == 0, precision is undefined; When true positive + false negative == 0, recall is undefined. In such cases, by default the metric will be set to 0, as will f-score, and UndefinedMetricWarning will be raised. This behavior can be modified with zero_division.

References

[1], [2], [3]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
(0.22..., 0.33..., 0.26..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
(0.22..., 0.33..., 0.26..., None)
```
It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging:

```python
>>> precision_recall_fscore_support(y_true, y_pred, average=None, ...
... labels=['pig', 'dog', 'cat'])
(array([0. , 0. , 0.66...]),
     array([0., 0., 1.]), array([0. , 0. , 0.8]),
     array([2, 2, 2]))
```

**sklearn.metrics.precision_score**

`sklearn.metrics.precision_score(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Compute the precision

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.
- `pos_label` [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- `average` [string, [None, 'binary' (default), ‘micro’, ‘macro’, ‘samples’, ‘weighted’]] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - `'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets `(y_{true, pred})` are binary.
  - `'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - `'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `'weighted'`: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

`sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

`zero_division` ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

**Returns**

- `precision` [float (if average is not None) or array of float, shape = [n_unique_labels]] Precision of the positive class in binary classification or weighted average of the precision of each class for the multiclass task.

**See also:**

`precision_recall_fscore_support`, `multilabel_confusion_matrix`

**Notes**

When `true positive + false positive == 0`, precision returns 0 and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

**Examples**

```python
got = precision_score(y_true, y_pred, average='macro')
got = precision_score(y_true, y_pred, average='micro')
got = precision_score(y_true, y_pred, average='weighted')
got = precision_score(y_true, y_pred, average=None)
got = precision_score(y_true, y_pred, average=None, zero_division=1)
```

**Examples using sklearn.metrics.precision_score**

- Probability Calibration curves
- Precision-Recall

**sklearn.metrics.recall_score**

`sklearn.metrics.recall_score` (y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')

Compute the recall
The recall is the ratio \( \frac{tp}{tp + fn} \) where \( tp \) is the number of true positives and \( fn \) the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels** [list, optional] The set of labels to include when \( \text{average} \neq \text{'binary'} \), and their order if \( \text{average} \) is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in \( y_{\text{true}} \) and \( y_{\text{pred}} \) are used in sorted order.

  Changed in version 0.17: parameter labels improved for multiclass problem.

- **pos_label** [str or int, 1 by default] The class to report if \( \text{average='binary'} \) and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and \( \text{average} \neq \text{'binary'} \) will report scores for that label only.

- **average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - **'binary'**: Only report results for the class specified by pos_label. This is applicable only if targets \( (y_{\text{true}}, y_{\text{pred}}) \) are binary.
  - **'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - **'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - **'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
  - **'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

- **sample_weight** [array-like of shape \( (n_{\text{samples}},) \), default=None] Sample weights.
- **zero_division** ['warn', 0 or 1, default='warn'] Sets the value to return when there is a zero division. If set to “warn”, this acts as 0, but warnings are also raised.

Returns

- **recall** [float (if average is not None) or array of float, shape = \([n_{\text{unique_labels}}]\)] Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

See also:

- precision_recall_fscore_support, balanced_accuracy_score
- multilabel_confusion_matrix
Notes

When \( \text{true positive} + \text{false negative} = 0 \), recall returns 0 and raises
\text{UndefinedMetricWarning}. This behavior can be modified with \text{zero_division}.

Examples

```python
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([1., 0., 0.])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> recall_score(y_true, y_pred, average=None)
array([0.5, 0., 0.])
>>> recall_score(y_true, y_pred, average=None, zero_division=1)
array([0.5, 1., 1.])
```

Examples using `sklearn.metrics.recall_score`

- Probability Calibration curves
- Precision-Recall

`sklearn.metrics.roc_auc_score`

`sklearn.metrics.roc_auc_score(y_true, y_score, average='macro', sample_weight=None, max_fpr=None, multi_class='raise', labels=None)`

Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.

Note: this implementation can be used with binary, multiclass and multilabel classification, but some restrictions apply (see Parameters).

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_classes)] True labels or binary label indicators. The binary and multiclass cases expect labels with shape (n_samples,) while the multilabel case expects binary label indicators with shape (n_samples, n_classes).

- `y_score` [array-like of shape (n_samples,) or (n_samples, n_classes)] Target scores. In the binary and multilabel cases, these can be either probability estimates or non-thresholded decision values (as returned by `decision_function` on some classifiers). In the multiclass case, these must be probability estimates which sum to 1. The binary case expects a shape (n_samples,), and the scores must be the scores of the class with the greater label. The multiclass and multilabel cases expect a shape (n_samples, n_classes). In the multiclass case, the order of the class scores must correspond to the order of labels, if provided, or else to the numerical or lexicographical order of the labels in `y_true`.  

7.24. `sklearn.metrics`: Metrics 2151
average  [[‘micro’,'macro', ‘samples’, ‘weighted’] or None, default=’macro’] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data: Note: multiclass ROC AUC currently only handles the ‘macro’ and ‘weighted’ averages.

‘micro’: Calculate metrics globally by considering each element of the label indicator matrix as a label.

‘macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

‘weighted’: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

‘samples’: Calculate metrics for each instance, and find their average.

Will be ignored when y_true is binary.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

max_fpr  [float > 0 and <= 1, default=None] If not None, the standardized partial AUC [2] over the range [0, max_fpr] is returned. For the multiclass case, max_fpr should be either equal to None or 1.0 as AUC ROC partial computation currently is not supported for multiclass.

multi_class  [[‘raise’, ‘ovr’, ‘ovo’], default=‘raise’] Multiclass only. Determines the type of configuration to use. The default value raises an error, so either ’ovr’ or ’ovo’ must be passed explicitly.

‘ovr’: Computes the AUC of each class against the rest [3] [4]. This treats the multiclass case in the same way as the multilabel case. Sensitive to class imbalance even when average == ‘macro’, because class imbalance affects the composition of each of the ‘rest’ groupings.

‘ovo’: Computes the average AUC of all possible pairwise combinations of classes [5]. Insensitive to class imbalance when average == ‘macro’.

labels  [array-like of shape (n_classes,), default=None] Multiclass only. List of labels that index the classes in y_score. If None, the numerical or lexicographical order of the labels in y_true is used.

Returns

auc  [float]

average_precision_score Area under the precision-recall curve
roc_curve Compute Receiver operating characteristic (ROC) curve

References

[1], [2], [3], [4], [5]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import roc_auc_score
>>> y_true = np.array([0, 0, 1, 1])
```
Examples using `sklearn.metrics.roc_auc_score`

- Receiver Operating Characteristic (ROC) with cross validation
- Receiver Operating Characteristic (ROC)
- Release Highlights for scikit-learn 0.22

`sklearn.metrics.roc_curve`

`sklearn.metrics.roc_curve(y_true, y_score, pos_label=None, sample_weight=None, drop_intermediate=True)`

Compute Receiver operating characteristic (ROC)

Note: this implementation is restricted to the binary classification task.

Read more in the User Guide.

Parameters

- `y_true` [array, shape = [n_samples]] True binary labels. If labels are not either {-1, 1} or {0, 1}, then `pos_label` should be explicitly given.
- `y_score` [array, shape = [n_samples]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `pos_label` [int or str, default=None] The label of the positive class. When `pos_label=None`, if `y_true` is in {-1, 1} or {0, 1}, `pos_label` is set to 1, otherwise an error will be raised.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `drop_intermediate` [boolean, optional (default=True)] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

Returns

- `fpr` [array, shape = [>2]] Increasing false positive rates such that element i is the false positive rate of predictions with score >= thresholds[i].
- `tpr` [array, shape = [>2]] Increasing true positive rates such that element i is the true positive rate of predictions with score >= thresholds[i].
- `thresholds` [array, shape = [n_thresholds]] Decreasing thresholds on the decision function used to compute fpr and tpr. `thresholds[0]` represents no instances being predicted and is arbitrarily set to `max(y_score) + 1`.

See also:

- `roc_auc_score` Compute the area under the ROC curve
Notes

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both \( fpr \) and \( tpr \), which are sorted in reversed order during their calculation.

References

[1], [2]

Examples

```python
>>> import numpy as np
>>> from sklearn import metrics

>>> y = np.array([1, 1, 2, 2])
>>> scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, scores, pos_label=2)
>>> fpr
array([0. , 0. , 0.5, 0.5, 1. ])
>>> tpr
array([0. , 0.5, 0.5, 1. , 1. ])
>>> thresholds
array([1.8 , 0.8 , 0.4 , 0.35, 0.1 ])
```

Examples using `sklearn.metrics.roc_curve`

- Feature transformations with ensembles of trees
- Species distribution modeling
- Receiver Operating Characteristic (ROC)

`sklearn.metrics.zero_one_loss`

`sklearn.metrics.zero_one_loss`(y_true, y_pred, normalize=True, sample_weight=None)

Zero-one classification loss.

If normalize is True, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Read more in the User Guide.

Parameters

- **y_true**: [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred**: [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **normalize**: [bool, optional (default=True)] If False, return the number of misclassifications. Otherwise, return the fraction of misclassifications.
- **sample_weight**: [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **loss**: [float or int] If normalize == True, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).
See also:

accuracy_score, hamming_loss, jaccard_score

Notes

In multilabel classification, the zero_one_loss function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

Examples

```python
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

Examples using sklearn.metrics.zero_one_loss

- Discrete versus Real AdaBoost

**sklearn.metrics.explained_variance_score**

*sklearn.metrics.explained_variance_score*(y_true, y_pred, sample_weight=None, multioutput='uniform_average')

Explained variance regression score function

Best possible score is 1.0, lower values are worse.

Read more in the *User Guide*.

**Parameters**

- **y_true** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- **y_pred** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- **sample_weight** [array-like of shape (n_samples,), optional] Sample weights.
- **multioutput** [string in ['raw_values', 'uniform_average', 'variance_weighted'] or array-like of shape (n_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.
  - ‘raw_values’ : Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’ : Scores of all outputs are averaged with uniform weight.
  - ‘variance_weighted’ : Scores of all outputs are averaged, weighted by the variances of each individual output.

**Returns**

- **score** [float or ndarray of floats] The explained variance or ndarray if ‘multioutput’ is ‘raw_values’.

**Notes**

This is not a symmetric function.

**Examples**

```python
>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
0.983...
```
sklearn.metrics.max_error

sklearn.metrics.max_error(y_true, y_pred)

max_error metric calculates the maximum residual error.

Read more in the User Guide.

Parameters

- y_true [array-like of shape (n_samples,)] Ground truth (correct) target values.
- y_pred [array-like of shape (n_samples,)] Estimated target values.

Returns

- max_error [float] A positive floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import max_error
>>> y_true = [3, 2, 7, 1]
>>> y_pred = [4, 2, 7, 1]
>>> max_error(y_true, y_pred)
1
```

sklearn.metrics.mean_absolute_error

sklearn.metrics.mean_absolute_error(y_true, y_pred, sample_weight=None, multioutput='uniform_average')

Mean absolute error regression loss

Read more in the User Guide.

Parameters

- y_true [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- y_pred [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- sample_weight [array-like of shape (n_samples,), optional] Sample weights.
- multioutput [string in ['raw_values', 'uniform_average'] or array-like of shape (n_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - ‘raw_values’ : Returns a full set of errors in case of multioutput input.
  - ‘uniform_average’ : Errors of all outputs are averaged with uniform weight.

Returns

- loss [float or ndarray of floats] If multioutput is ‘raw_values’, then mean absolute error is returned for each output separately. If multioutput is ‘uniform_average’ or an ndarray of weights, then the weighted average of all output errors is returned. MAE output is non-negative floating point. The best value is 0.0.
Examples

```python
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85...
```

```
scikit-learn user guide, Release 0.22.1

Examples

```python
>>> from sklearn.metrics import mean_squared_error

sklearn.metrics.mean_squared_error

Parameters

y_true [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
y_pred [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
sample_weight [array-like of shape (n_samples,), optional] Sample weights.
multioutput [string in ['raw_values', 'uniform_average'] or array-like of shape (n_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
    'raw_values': Returns a full set of errors in case of multioutput input.
    'uniform_average': Errors of all outputs are averaged with uniform weight.
squared [boolean value, optional (default = True)] If True returns MSE value, if False returns RMSE value.

Returns

loss [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```python
>>> from sklearn.metrics import mean_squared_error

>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
```
Examples using `sklearn.metrics.mean_squared_error`

- Gradient Boosting regression
- Model Complexity Influence
- Plot Ridge coefficients as a function of the L2 regularization
- Linear Regression Example
- Robust linear estimator fitting

`sckitlearn.metrics.mean_squared_log_error`

`sckitlearn.metrics.mean_squared_log_error` *(y_true, y_pred, sample_weight=None, multioutput='uniform_average')*

Mean squared logarithmic error regression loss

Read more in the *User Guide*.

**Parameters**

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), optional] Sample weights.
- `multioutput` [string in ['raw_values', 'uniform_average'] or array-like of shape (n_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

- `'raw_values'`: Returns a full set of errors when the input is of multioutput format.
- `'uniform_average'`: Errors of all outputs are averaged with uniform weight.

**Returns**

- `loss` [float or array of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

**Examples**
```python
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...
>>> y_true = [[0.5, 1], [1, 2], [7, 6]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...
>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
array([0.00462428, 0.08377444])
>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.060...
```

**sklearn.metrics.median_absolute_error**

`sklearn.metrics.median_absolute_error(y_true, y_pred, multioutput='uniform_average')`

Median absolute error regression loss

Median absolute error output is non-negative floating point. The best value is 0.0. Read more in the *User Guide*.

**Parameters**

- `y_true` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
- `multioutput` ['raw_values', 'uniform_average'] or array-like of shape (n_outputs,) Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - `'raw_values'` : Returns a full set of errors in case of multioutput input.
  - `'uniform_average'` : Errors of all outputs are averaged with uniform weight.

**Returns**

- `loss` [float or ndarray of floats] If multioutput is 'raw_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform_average' or an ndarray of weights, then the weighted average of all output errors is returned.

**Examples**

```python
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> median_absolute_error(y_true, y_pred)
0.75
>>> median_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.])
>>> median_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85
```
**Examples using sklearn.metrics.median_absolute_error**

- Effect of transforming the targets in regression model

**sklearn.metrics.r2_score**

sklearn.metrics.r2_score(y_true, y_pred, sample_weight=None, multioutput='uniform_average')

R^2 (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Read more in the User Guide.

**Parameters**

- y_true [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- y_pred [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- sample_weight [array-like of shape (n_samples,), optional] Sample weights.
- multioutput [string in ['raw_values', 'uniform_average', 'variance_weighted'] or None or array-like of shape (n_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is “uniform_average”.
  - ‘raw_values’: Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’: Scores of all outputs are averaged with uniform weight.
  - ‘variance_weighted’: Scores of all outputs are averaged, weighted by the variances of each individual output.

Changed in version 0.19: Default value of multioutput is ‘uniform_average’.

**Returns**

- z [float or ndarray of floats] The R^2 score or ndarray of scores if ‘multioutput’ is ‘raw_values’.

**Notes**

This is not a symmetric function.

Unlike most other scores, R^2 score may be negative (it need not actually be the square of a quantity R).

This metric is not well-defined for single samples and will return a NaN value if n_samples is less than two.

**References**

[1]

**Examples**
Example using `sklearn.metrics.r2_score`

```python
>>> from sklearn.metrics import r2_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...
```

```python
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred, multioutput='variance_weighted')
0.938...
```

```python
>>> y_true = [1, 2, 3]
>>> y_pred = [1, 2, 3]
>>> r2_score(y_true, y_pred)
1.0
```

```python
>>> y_true = [1, 2, 3]
>>> y_pred = [2, 2, 2]
>>> r2_score(y_true, y_pred)
0.0
```

```python
>>> y_true = [1, 2, 3]
>>> y_pred = [3, 2, 1]
>>> r2_score(y_true, y_pred)
-3.0
```

**sklearn.metrics.mean_poisson_deviance**

`sklearn.metrics.mean_poisson_deviance(y_true, y_pred, sample_weight=None)`

Mean Poisson deviance regression loss.

Poisson deviance is equivalent to the Tweedie deviance with the power parameter $p=1$.

Read more in the *User Guide*.

**Parameters**

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values. Requires y_true $\geq 0$.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values. Requires y_pred $> 0$.
- `sample_weight` [array-like, shape (n_samples,), optional] Sample weights.

**Returns**

- `loss` [float] A non-negative floating point value (the best value is 0.0).

**Examples**
```python
>>> from sklearn.metrics import mean_poisson_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_poisson_deviance(y_true, y_pred)
1.4260...
```

**scikit-learn.metrics.mean_gamma_deviance**

`scikit-learn.metrics.mean_gamma_deviance(y_true, y_pred, sample_weight=None)`

Mean Gamma deviance regression loss.

Gamma deviance is equivalent to the Tweedie deviance with the power parameter $p=2$. It is invariant to scaling of the target variable, and measures relative errors.

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values. Requires $y_{true} > 0$.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values. Requires $y_{pred} > 0$.
- `sample_weight` [array-like, shape (n_samples,), optional] Sample weights.

**Returns**

- `loss` [float] A non-negative floating point value (the best value is 0.0).

**Examples**

```python
>>> from sklearn.metrics import mean_gamma_deviance
>>> y_true = [2, 0.5, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_gamma_deviance(y_true, y_pred)
1.0568...
```

**scikit-learn.metrics.mean_tweedie_deviance**

`scikit-learn.metrics.mean_tweedie_deviance(y_true, y_pred, sample_weight=None, power=0)`

Mean Tweedie deviance regression loss.

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values.
- `sample_weight` [array-like, shape (n_samples,), optional] Sample weights.
- `power` [float, default=0] Tweedie power parameter. Either `power <= 0` or `power >= 1`.

The higher $p$ the less weight is given to extreme deviations between true and predicted targets.

- `power < 0`: Extreme stable distribution. Requires: $y_{pred} > 0$.
• power = 0: Normal distribution, output corresponds to mean_squared_error. y_true and y_pred can be any real numbers.
• power = 1: Poisson distribution. Requires: y_true >= 0 and y_pred > 0.
• 1 < p < 2: Compound Poisson distribution. Requires: y_true >= 0 and y_pred > 0.
• power = 2: Gamma distribution. Requires: y_true > 0 and y_pred > 0.
• power = 3: Inverse Gaussian distribution. Requires: y_true > 0 and y_pred > 0.
• otherwise: Positive stable distribution. Requires: y_true > 0 and y_pred > 0.

Returns

loss [float] A non-negative floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import mean_tweedie_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_tweedie_deviance(y_true, y_pred, power=1)
1.4260...
```

7.24.4 Multilabel ranking metrics

See the `Multilabel ranking metrics` section of the user guide for further details.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>metrics.coverage_error</code></td>
<td>Coverage error measure</td>
</tr>
<tr>
<td><code>metrics.label_ranking_average_precision</code></td>
<td>Compute ranking-based average precision</td>
</tr>
<tr>
<td><code>metrics.label_ranking_loss</code></td>
<td>Compute Ranking loss measure</td>
</tr>
</tbody>
</table>

`sklearn.metrics.coverage_error`

`sklearn.metrics.coverage_error(y_true, y_score, sample_weight=None)`

Coverage error measure

Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in y_true per sample.

Ties in y_scores are broken by giving maximal rank that would have been assigned to all tied values.

Note: Our implementation’s score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.

Read more in the `User Guide`.

Parameters

- `y_true` [array, shape = [n_samples, n_labels]] True binary labels in binary indicator format.
- `y_score` [array, shape = [n_samples, n_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

coverage_error  [float]

References

[1]

sklearn.metrics.label_ranking_average_precision_score

sklearn.metrics.label_ranking_average_precision_score(y_true, y_score, sample_weight=None)

Compute ranking-based average precision

Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.

This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.

The obtained score is always strictly greater than 0 and the best value is 1.

Read more in the User Guide.

Parameters

- **y_true** [array or sparse matrix, shape = [n_samples, n_labels]] True binary labels in binary indicator format.
- **y_score** [array, shape = [n_samples, n_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

sklearn.metrics.label_ranking_loss

sklearn.metrics.label_ranking_loss(y_true, y_score, sample_weight=None)

Compute Ranking loss measure

Compute the average number of label pairs that are incorrectly ordered given y_score weighted by the size of the label set and the number of labels not in the label set.
This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.

Read more in the User Guide.

New in version 0.17: A function `label_ranking_loss`

**Parameters**

- `y_true` [array or sparse matrix, shape = [n_samples, n_labels]] True binary labels in binary indicator format.
- `y_score` [array, shape = [n_samples, n_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `loss` [float]

**References**

[1]

### 7.24.5 Clustering metrics

See the Clustering performance evaluation section of the user guide for further details.

The `sklearn.metrics.cluster` submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the ‘quality’ of the model itself.

```python
metrics.adjusted_mutual_info_score(...[, ...,])
metrics.adjusted_rand_score(labels_true,...)
metrics.calinski_harabasz_score(X, labels)
metrics.davies_bouldin_score(X, labels)
metrics.completeness_score(labels_true,...)
metrics.cluster.contingency_matrix(...[, ...])
metrics.fowlkes_mallows_score(labels_true,...)
metrics.homogeneity_completeness_v_measure(...)
metrics.homogeneity_score(labels_true,...)
metrics.mutual_info_score(labels_true,...)
```

Continued on next page
Table 192 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>metrics.normalized_mutual_info_score(...)</code></td>
<td>Normalized Mutual Information between two clusterings.</td>
</tr>
<tr>

<td>Compute the mean Silhouette Coefficient of all samples.</td>
</tr>
<tr>
<td><code>metrics.silhouette_samples(X, labels,...)</code></td>
<td>Compute the Silhouette Coefficient for each sample.</td>
</tr>
<tr>
<td><code>metrics.v_measure_score(labels_true, labels_pred)</code></td>
<td>V-measure cluster labeling given a ground truth.</td>
</tr>
</tbody>
</table>

**sklearn.metrics.adjusted_mutual_info_score**

Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings $U$ and $V$, the AMI is given as:

$$AMI(U, V) = \frac{MI(U, V) - E(MI(U, V))}{avg(H(U), H(V)) - E(MI(U, V))}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the User Guide.

Parameters

- `labels_true` [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `labels_pred` [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.
- `average_method` [string, optional (default: ‘arithmetic’)] How to compute the normalizer in the denominator. Possible options are ‘min’, ‘geometric’, ‘arithmetic’, and ‘max’.

New in version 0.20.

Changed in version 0.22: The default value of `average_method` changed from ‘max’ to ‘arithmetic’.

Returns

- `ami`: float (upperlimited by 1.0) The AMI returns a value of 1 when the two partitions are identical (i.e., perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

See also:

- `adjusted_rand_score` Adjusted Rand Index
- `mutual_info_score` Mutual Information (not adjusted for chance)
References

[1], [2]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
... 1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
... 1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the AMI is null:

```python
>>> adjusted_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
... 0.0
```

Examples using sklearn.metrics.adjusted_mutual_info_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data

sklearn.metrics.adjusted_rand_score

```python
sklearn.metrics.adjusted_rand_score(labels_true, labels_pred)
```

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then “adjusted for chance” into the ARI score using the following scheme:

```
ARI = (RI - Expected_RI) / (max(RI) - Expected_RI)
```

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

```
adjusted_rand_score(a, b) == adjusted_rand_score(b, a)
```

Read more in the User Guide.

Parameters

- **labels_true** [int array, shape = [n_samples]] Ground truth class labels to be used as a reference
labels_pred [array-like of shape (n_samples,)] Cluster labels to evaluate

Returns

ari [float] Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

See also:

adjusted_mutual_info_score Adjusted Mutual Information

References

[Hubert1985], [wk]

Examples

Perfectly matching labelings have a score of 1 even

```python
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not always pure, hence penalized:

```python
>>> adjusted_rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.57...
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:

```python
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 2])
0.57...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

```python
>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

Examples using sklearn.metrics.adjusted_rand_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means
**sklearn.metrics.calinski_harabasz_score**

`sklearn.metrics.calinski_harabasz_score(X, labels)`
Compute the Calinski and Harabasz score.

It is also known as the Variance Ratio Criterion.

The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
- **labels** [array-like, shape (n_samples,)] Predicted labels for each sample.

**Returns**

- **score** [float] The resulting Calinski-Harabasz score.

**References**

[1]

---

**sklearn.metrics.davies_bouldin_score**

`sklearn.metrics.davies_bouldin_score(X, labels)`
Computes the Davies-Bouldin score.

The score is defined as the average similarity measure of each cluster with its most similar cluster, where similarity is the ratio of within-cluster distances to between-cluster distances. Thus, clusters which are farther apart and less dispersed will result in a better score.

The minimum score is zero, with lower values indicating better clustering.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
- **labels** [array-like, shape (n_samples,)] Predicted labels for each sample.

**Returns**

- **score**: float The resulting Davies-Bouldin score.

**References**

[1]
**sklearn.metrics.completeness_score**

sklearn.metrics.completeness_score(labels_true, labels_pred)

Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is not symmetric: switching label_true with label_pred will return the homogeneity_score which will be different in general.

Read more in the User Guide.

**Parameters**

- labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- labels_pred [array-like of shape (n_samples,)] cluster labels to evaluate

**Returns**

- completeness [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

**See also:**

- homogeneity_score
- v_measure_score

**References**

[1]

**Examples**

Perfect labelings are complete:

```python
>>> from sklearn.metrics.cluster import completeness_score
>>> completeness_score([[0, 0, 1, 1], [1, 1, 0, 0]])
1.0
```

Non-perfect labelings that assign all classes members to the same clusters are still complete:

```python
>>> print(completeness_score([[0, 0, 1, 1], [0, 0, 0, 0]]))
1.0
>>> print(completeness_score([[0, 1, 2, 3], [0, 0, 1, 1]]))
0.999...
```

If classes members are split across different clusters, the assignment cannot be complete:

```python
>>> print(completeness_score([[0, 0, 1, 1], [0, 1, 0, 1]]))
0.0
>>> print(completeness_score([[0, 0, 0, 0], [0, 1, 2, 3]]))
0.0
```
Examples using `sklearn.metrics.completeness_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`sklearn.metrics.cluster.contingency_matrix`

`sklearn.metrics.cluster.contingency_matrix(labels_true, labels_pred, eps=None, sparse=False)`

Build a contingency matrix describing the relationship between labels.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] Ground truth class labels to be used as a reference
- `labels_pred` [array-like of shape (n_samples,)] Cluster labels to evaluate
- `eps` [None or float, optional.] If a float, that value is added to all values in the contingency matrix. This helps to stop NaN propagation. If None, nothing is adjusted.
- `sparse` [boolean, optional.] If True, return a sparse CSR continency matrix. If `eps` is not None, and `sparse` is True, will throw ValueError.

**Returns**

- `contingency` [[array-like, sparse], shape=[n_classes_true, n_classes_pred]] Matrix $C$ such that $C_{ij}$ is the number of samples in true class $i$ and in predicted class $j$. If `eps` is None, the dtype of this array will be integer. If `eps` is given, the dtype will be float. Will be a `scipy.sparse.csr_matrix` if `sparse=True`.

`sklearn.metrics.fowlkes_mallows_score`

`sklearn.metrics.fowlkes_mallows_score(labels_true, labels_pred, sparse=False)`

Measure the similarity of two clusterings of a set of points.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between the precision and recall:

\[
\text{FMI} = \frac{TP}{\sqrt{(TP + FP) \times (TP + FN)}}
\]

Where $TP$ is the number of True Positive (i.e. the number of pair of points that belongs in the same clusters in both `labels_true` and `labels_pred`), $FP$ is the number of False Positive (i.e. the number of pair of points that belongs in the same clusters in `labels_true` and not in `labels_pred`) and $FN$ is the number of False Negative (i.e. the number of pair of points that belongs in the same clusters in `labels_pred` and not in `labels_true`).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the User Guide.

**Parameters**

- `labels_true` [int array, shape = (n_samples,)] A clustering of the data into disjoint subsets.
- `labels_pred` [array, shape = (n_samples,)] A clustering of the data into disjoint subsets.
**sparse** [bool] Compute contingency matrix internally with sparse matrix.

**Returns**

**score** [float] The resulting Fowlkes-Mallows score.

**References**

[1], [2]

**Examples**

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> fowlkes_mallows_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:

```python
>>> fowlkes_mallows_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

**sklearn.metrics.homogeneity_completeness_v_measure**

**sklearn.metrics.homogeneity_completeness_v_measure**(labels_true, labels_pred, beta=1.0)

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score values in any way.

V-Measure is furthermore symmetric: swapping labels_true and label_pred will give the same score. This does not hold for homogeneity and completeness. V-Measure is identical to normalized_mutual_info_score with the arithmetic averaging method.

Read more in the User Guide.

**Parameters**

**labels_true** [int array, shape = [n_samples]] ground truth class labels to be used as a reference

**labels_pred** [array-like of shape (n_samples,)] cluster labels to evaluate
**beta** [float] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

**Returns**

- **homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling
- **completeness** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling
- **v_measure** [float] harmonic mean of the first two

See also:

- `homogeneity_score`
- `completeness_score`
- `v_measure_score`

**sklearn.metrics.homogeneity_score**

`sklearn.metrics.homogeneity_score(labels_true, labels_pred)`

Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is not symmetric: switching `labels_true` with `labels_pred` will return the `completeness_score` which will be different in general.

Read more in the User Guide.

**Parameters**

- **labels_true** [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- **labels_pred** [array-like of shape (n_samples,)] cluster labels to evaluate

**Returns**

- **homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

See also:

- `completeness_score`
- `v_measure_score`

**References**

[1]
Examples

Perfect labelings are homogeneous:

```python
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
1.000000
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
1.000000
```

Clusters that include samples from different classes do not make for an homogeneous labeling:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```

Examples using `sklearn.metrics.homogeneity_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

**sklearn.metrics.mutual_info_score**

`sklearn.metrics.mutual_info_score(labels_true, labels_pred, contingency=None)`

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where \(|U_i|\) is the number of the samples in cluster \(U_i\) and \(|V_j|\) is the number of the samples in cluster \(V_j\), the Mutual Information between clusterings \(U\) and \(V\) is given as:

\[
MI(U, V) = \sum_{i=1}^{[U]} \sum_{j=1}^{[V]} \frac{|U_i \cap V_j|}{N} \log \frac{N|U_i \cap V_j|}{|U_i||V_j|}
\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `labels_pred` [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.

7.24. sklearn.metrics: Metrics
contingency  [[None, array, sparse matrix], shape = [n_classes_true, n_classes_pred]] A contingency matrix given by the `contingency_matrix` function. If value is None, it will be computed, otherwise the given value is used, with `labels_true` and `labels_pred` ignored.

Returns

mi  [float] Mutual information, a non-negative value

See also:

adjusted_mutual_info_score  Adjusted against chance Mutual Information

normalized_mutual_info_score  Normalized Mutual Information

Notes

The logarithm used is the natural logarithm (base-e).

Examples using `sklearn.metrics.mutual_info_score`

- Adjustment for chance in clustering performance evaluation

`sklearn.metrics.normalized_mutual_info_score`

`sklearn.metrics.normalized_mutual_info_score`  (`labels_true`, `labels_pred`, `average_method='arithmetic'`)  

Normalized Mutual Information between two clusterings.

Normalized Mutual Information (NMI) is a normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by some generalized mean of $H(labels\_true)$ and $H(labels\_pred)$, defined by the `average_method`.

This measure is not adjusted for chance. Therefore `adjusted_mutual_info_score` might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

Parameters

labels_true  [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.

labels_pred  [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.

average_method  [string, optional (default: ‘arithmetic’)] How to compute the normalizer in the denominator. Possible options are ‘min’, ‘geometric’, ‘arithmetic’, and ‘max’.

New in version 0.20.

Changed in version 0.22: The default value of `average_method` changed from ‘geometric’ to ‘arithmetic’.

Returns
nmi [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

v_measure_score V-Measure (NMI with arithmetic mean option.)
adjusted_rand_score Adjusted Rand Index
adjusted_mutual_info_score Adjusted Mutual Information (adjusted against chance)

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the NMI is null:

```python
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

**sklearn.metrics.silhouette_score**

sklearn.metrics.silhouette_score(X, labels, metric='euclidean', sample_size=None, random_state=None, **kwds)

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance \( a \) and the mean nearest-cluster distance \( b \) for each sample. The Silhouette Coefficient for a sample is \( (b - a) / \max(a, b) \). To clarify, \( b \) is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficient is only defined if number of labels is \( 2 \leq n_{labels} \leq n_{samples} - 1 \).

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use silhouette_samples.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the User Guide.

Parameters

- X [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.
- labels [array, shape = [n_samples]] Predicted labels for each sample.
- metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by metrics.pairwise.pairwise_distances. If X is the distance array itself, use metric="precomputed".
sample_size [int or None] The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If sample_size is None, no sampling is used.

random_state [int, RandomState instance or None, optional (default=None)] The generator used to randomly select a subset of samples. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when sample_size is not None.

**kwds [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns

silhouette [float] Mean Silhouette Coefficient for all samples.

References

[1], [2]

Examples using sklearn.metrics.silhouette_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Selecting the number of clusters with silhouette analysis on KMeans clustering
- Clustering text documents using k-means

sklearn.metrics.silhouette_samples

sklearn.metrics.silhouette_samples (X, labels, metric='euclidean', **kwds)

Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (a) and the mean nearest-cluster distance (b) for each sample. The Silhouette Coefficient for a sample is \((b - a) / \max(a, b)\). Note that Silhouette Coefficient is only defined if number of labels is 2 <= n_labels <= n_samples - 1.

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

Read more in the User Guide.

Parameters

X [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.

labels [array, shape = [n_samples]] label values for each sample
**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `sklearn.metrics.pairwise.pairwise_distances`. If X is the distance array itself, use “precomputed” as the metric. Precomputed distance matrices must have 0 along the diagonal.

```markdown
**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the scipy docs for usage examples.
```

**Returns**

- **silhouette** [array, shape = [n_samples]] Silhouette Coefficient for each samples.

**References**

[1], [2]

**Examples using sklearn.metrics.silhouette_samples**

- Selecting the number of clusters with silhouette analysis on KMeans clustering

```python
sklearn.metrics.v_measure_score
```

`sklearn.metrics.v_measure_score(labels_true, labels_pred, beta=1.0)`

V-measure cluster labeling given a ground truth.

This score is identical to `normalized_mutual_info_score` with the 'arithmetic' option for averaging.

The V-measure is the harmonic mean between homogeneity and completeness:

```latex
v = \frac{(1 + \beta) \times \text{homogeneity} \times \text{completeness}}{\beta \times \text{homogeneity} + \text{completeness}}
```

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- `labels_pred` [array-like of shape (n_samples,)] cluster labels to evaluate
- `beta` [float] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

**Returns**

- **v_measure** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:
Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not homogeneous, hence penalized:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.66...
```

Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```python
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```

### Examples using sklearn.metrics.v_measure_score

- Biclustering documents with the Spectral Co-clustering algorithm
- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
• Adjustment for chance in clustering performance evaluation
• A demo of K-Means clustering on the handwritten digits data
• Clustering text documents using k-means

7.24.6 Biclustering metrics

See the Biclustering evaluation section of the user guide for further details.

\[
\text{metrics.consensus_score}(a, b[, \text{similarity}])
\]

The similarity of two sets of biclusters.

```
from sklearn.metrics import consensus_score

# Example usage
a = ((row_1, column_1), (row_2, column_2))
b = ((row_3, column_3), (row_4, column_4))
similarity = 'jaccard'
similarity_score = consensus_score(a, b, similarity)
```

`sklearn.metrics.consensus_score`

```
sklearn.metrics.consensus_score(a, b, similarity='jaccard')
```

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the User Guide.

Parameters

- `a`: [(rows, columns)] Tuple of row and column indicators for a set of biclusters.
- `b`: [(rows, columns)] Another set of biclusters like `a`.
- `similarity` [string or function, optional, default: “jaccard”] May be the string “jaccard” to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a_rows, a_columns, b_rows, b_columns).

7.24.7 Pairwise metrics

See the Pairwise metrics, Affinities and Kernels section of the user guide for further details.

```
from sklearn.metrics.pairwise import additive_chi2_kernel, chi2_kernel, cosine_similarity

# Example usage
X = [[1, 2], [3, 4], [5, 6]]
Y = [[7, 8], [9, 10], [11, 12]]

# Computes the additive chi-squared kernel between observations in X and Y
additive_chi2_kernel(X, Y)

# Computes the exponential chi-squared kernel X and Y
chi2_kernel(X, gamma=1.0)

# Compute cosine similarity between samples in X and Y
cosine_similarity(X, Y, dense_output=False)
```

**sklearn.metrics.pairwise.additive_chi2_kernel**

Computes the additive chi-squared kernel between observations in X and Y.

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:
\[ k(x, y) = -\sum \frac{(x - y)^2}{(x + y)} \]

It can be interpreted as a weighted difference per entry.
Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples_X, n_features)]
- **Y** [array of shape (n_samples_Y, n_features)]

Returns

- **kernel_matrix** [array of shape (n_samples_X, n_samples_Y)]

See also:

- **chi2_kernel** The exponentiated version of the kernel, which is usually preferable.
- **sklearn.kernel_approximation.AdditiveChi2Sampler** A Fourier approximation to this kernel.

Notes

As the negative of a distance, this kernel is only conditionally positive definite.

References

**sklearn.metrics.pairwise.chi2_kernel**

Computes the exponential chi-squared kernel \( X \) and \( Y \).

The chi-squared kernel is computed between each pair of rows in \( X \) and \( Y \). \( X \) and \( Y \) have to be non-negative.
This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

\[ k(x, y) = \exp(-\gamma \sum \frac{(x - y)^2}{(x + y)}) \]

It can be interpreted as a weighted difference per entry.
Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples_X, n_features)]
- **Y** [array of shape (n_samples_Y, n_features)]
- **gamma** [float, default=1.0] Scaling parameter of the chi2 kernel.

Returns

- **kernel_matrix** [array of shape (n_samples_X, n_samples_Y)]
See also:

- `additive_chi2_kernel` The additive version of this kernel
- `sklearn.kernel_approximation.AdditiveChi2Sampler` A Fourier approximation to the additive version of this kernel.

References

`sklearn.metrics.pairwise.cosine_similarity`

`sklearn.metrics.pairwise.cosine_similarity(X, Y=None, dense_output=True)`

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

\[ K(X, Y) = \frac{<X, Y>}{\|X\| \|Y\|} \]

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the User Guide.

Parameters

- **X** [ndarray or sparse array, shape (n_samples_X, n_features)] Input data.
- **Y** [ndarray or sparse array, shape (n_samples_Y, n_features)] Input data. If None, the output will be the pairwise similarities between all samples in X.
- **dense_output** [boolean (optional), default True] Whether to return dense output even when the input is sparse. If False, the output is sparse if both input arrays are sparse.

Returns

- **kernel matrix** [array] An array with shape (n_samples_X, n_samples_Y).

`sklearn.metrics.pairwise.cosine_distances`

`sklearn.metrics.pairwise.cosine_distances(X, Y=None)`

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the User Guide.

Parameters

- **X** [array_like, sparse matrix] with shape (n_samples_X, n_features).
- **Y** [array_like, sparse matrix (optional)] with shape (n_samples_Y, n_features).

Returns

- **distance matrix** [array] An array with shape (n_samples_X, n_samples_Y).

See also:
sklearn.metrics.pairwise.cosine_similarity

scipy.spatial.distance.cosine  dense matrices only

sklearn.metrics.pairwise.distance_metrics

sklearn.metrics.pairwise.distance_metrics()

Valid metrics for pairwise_distances.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>

Read more in the User Guide.

sklearn.metrics.pairwise.euclidean_distances

sklearn.metrics.pairwise.euclidean_distances(X, Y=None, Y_norm_squared=None, squared=False, X_norm_squared=None)

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:

\[
\text{dist}(x, y) = \sqrt{\text{dot}(x, x) - 2 \times \text{dot}(x, y) + \text{dot}(y, y)}
\]

This formulation has two advantages over other ways of computing distances. First, it is computationally efficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then \(\text{dot}(x, x)\) and/or \(\text{dot}(y, y)\) can be pre-computed.

However, this is not the most precise way of doing this computation, and the distance matrix returned by this function may not be exactly symmetric as required by, e.g., scipy.spatial.distance functions.

Read more in the User Guide.

Parameters

- X [[array-like, sparse matrix], shape (n_samples_1, n_features)]
- Y [[array-like, sparse matrix], shape (n_samples_2, n_features)]
- Y_norm_squared [array-like, shape (n_samples_2, ), optional] Pre-computed dot-products of vectors in Y (e.g., \((Y**2).\sum(\text{axis}=1)\)) May be ignored in some cases, see the note below.
**X_norm_squared** [array-like of shape (n_samples,), optional] Pre-computed dot-products of vectors in X (e.g., \((X**2).sum(axis=1))\) May be ignored in some cases, see the note below.

Returns

**distances** [array, shape (n_samples_1, n_samples_2)]

See also:

**paired_distances** distances betweens pairs of elements of X and Y.

Notes

To achieve better accuracy, X_norm_squared and Y_norm_squared may be unused if they are passed as float32.

Examples

```python
>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[0., 1.],
       [1., 0.]])
>>> # get distance to origin
>>> euclidean_distances(X, [[0, 0]])
array([[1.41421356]])
```

**sklearn.metrics.pairwise.haversine_distances**

**sklearn.metrics.pairwise.haversine_distances** \((X, Y=None)\)

Compute the Haversine distance between samples in X and Y

The Haversine (or great circle) distance is the angular distance between two points on the surface of a sphere. The first distance of each point is assumed to be the latitude, the second is the longitude, given in radians. The dimension of the data must be 2.

\[
D(x, y) = 2 \arcsin\left(\sqrt{\sin^2((x_1 - y_1)/2) + \cos(x_1) \cos(y_1) \sin^2((x_2 - y_2)/2)}\right)
\]

Parameters

- **X** [array_like, shape (n_samples_1, 2)]
- **Y** [array_like, shape (n_samples_2, 2), optional]

Returns

**distance** [{array}, shape (n_samples_1, n_samples_2)]

Notes

As the Earth is nearly spherical, the haversine formula provides a good approximation of the distance between two points of the Earth surface, with a less than 1% error on average.
Examples

We want to calculate the distance between the Ezeiza Airport (Buenos Aires, Argentina) and the Charles de Gaulle Airport (Paris, France)

```python
>>> from sklearn.metrics.pairwise import haversine_distances
>>> from math import radians

>>> bsas = [-34.83333, -58.5166646]
>>> paris = [49.0083899664, 2.53844117956]
>>> bsas_in_radians = [radians(_) for _ in bsas]
>>> paris_in_radians = [radians(_) for _ in paris]
>>> result = haversine_distances([bsas_in_radians, paris_in_radians])
>>> result * 6371000/1000  # multiply by Earth radius to get kilometers
array([[ 0. , 11099.54035582],
       [11099.54035582,  0. ]])
```

**sklearn.metrics.pairwise.kernel_metrics**

**sklearn.metrics.pairwise.kernel_metrics()**

Valid metrics for pairwise_kernels

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>
<thead>
<tr>
<th>metric</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'additive_chi2'</td>
<td>sklearn.pairwise.additive_chi2_kernel</td>
</tr>
<tr>
<td>'chi2'</td>
<td>sklearn.pairwise.chi2_kernel</td>
</tr>
<tr>
<td>'linear'</td>
<td>sklearn.pairwise.linear_kernel</td>
</tr>
<tr>
<td>'poly'</td>
<td>sklearn.pairwise.polynomial_kernel</td>
</tr>
<tr>
<td>'polynomial'</td>
<td>sklearn.pairwise.polynomial_kernel</td>
</tr>
<tr>
<td>'rbf'</td>
<td>sklearn.pairwise.rbf_kernel</td>

<td>sklearn.pairwise.sigmoid_kernel</td>
</tr>
<tr>
<td>'cosine'</td>
<td>sklearn.pairwise.cosine_similarity</td>
</tr>
</tbody>
</table>

Read more in the **User Guide**.

**sklearn.metrics.pairwise.laplacian_kernel**

**sklearn.metrics.pairwise.laplacian_kernel(X, Y=None, gamma=None)**

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

\[
K(x, y) = \exp(-\gamma \|x-y\|_1)
\]

for each pair of rows x in X and y in Y. Read more in the **User Guide**.

New in version 0.17.

**Parameters**

- **X** [array of shape (n_samples_X, n_features)]
Y [array of shape (n_samples_Y, n_features)]
gamma [float, default None] If None, defaults to 1.0 / n_features

Returns
  kernel_matrix [array of shape (n_samples_X, n_samples_Y)]

sklearn.metrics.pairwise.linear_kernel

sklearn.metrics.pairwise.linear_kernel (X, Y=None, dense_output=True)
Compute the linear kernel between X and Y.
Read more in the User Guide.

Parameters
  X [array of shape (n_samples_1, n_features)]
  Y [array of shape (n_samples_2, n_features)]
  dense_output [boolean (optional), default True] Whether to return dense output even when the input is sparse. If False, the output is sparse if both input arrays are sparse.

New in version 0.20.

Returns
  Gram matrix [array of shape (n_samples_1, n_samples_2)]

sklearn.metrics.pairwise.manhattan_distances

sklearn.metrics.pairwise.manhattan_distances (X, Y=None, sum_over_features=True)
Compute the L1 distances between the vectors in X and Y.
With sum_over_features equal to False it returns the componentwise distances.
Read more in the User Guide.

Parameters
  X [array_like] An array with shape (n_samples_X, n_features).
  sum_over_features [bool, default=True] If True the function returns the pairwise distance matrix else it returns the componentwise L1 pairwise-distances. Not supported for sparse matrix inputs.

Returns
  D [array] If sum_over_features is False shape is (n_samples_X * n_samples_Y, n_features) and D contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n_samples_X, n_samples_Y) and D contains the pairwise L1 distances.

Notes

When X and/or Y are CSR sparse matrices and they are not already in canonical format, this function modifies them in-place to make them canonical.
Examples

```python
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[3]], [[3]])
array([[0.]])
>>> manhattan_distances([[3]], [[2]])
array([[1.]])
>>> manhattan_distances([[2]], [[3]])
array([[1.]])
>>> manhattan_distances([[1, 2], [3, 4]], [[1, 2], [0, 3]])
array([[0., 2.],
       [4., 4.]])
>>> import numpy as np
>>> X = np.ones((1, 2))
>>> y = np.full((2, 2), 2.)
>>> manhattan_distances(X, y, sum_over_features=False)
array([[1., 1.],
       [1., 1.]])
```

**sklearn.metrics.pairwise.nan_euclidean_distances**

The function `sklearn.metrics.pairwise.nan_euclidean_distances` is used to calculate the Euclidean distances in the presence of missing values. It computes the Euclidean distance between each pair of samples in `X` and `Y`, where `Y=X` is assumed if `Y` is not specified. When calculating the distance between a pair of samples, this formulation ignores feature coordinates with a missing value in either sample and scales up the weight of the remaining coordinates:

\[ \text{dist}(x,y) = \sqrt{\text{weight} \times \text{sq. distance from present coordinates}} \]

where \( \text{weight} = \frac{\text{Total # of coordinates}}{\# \text{ of present coordinates}} \)

For example, the distance between \([3, na, na, 6]\) and \([1, na, 4, 5]\) is:

\[ \sqrt{\frac{4}{2}((3-1)^2 + (6-5)^2)} \]

If all the coordinates are missing or if there are no common present coordinates then NaN is returned for that pair.

Read more in the User Guide.

New in version 0.22.

**Parameters**

- **X** [array-like, shape=(n_samples_1, n_features)]
- **Y** [array-like, shape=(n_samples_2, n_features)]
- **squared** [bool, default=False] Return squared Euclidean distances.
- **missing_values** [np.nan or int, default=np.nan] Representation of missing value
- **copy** [boolean, default=True] Make and use a deep copy of X and Y (if Y exists)

**Returns**

- **distances** [array, shape (n_samples_1, n_samples_2)]
See also:

**paired_distances** distances between pairs of elements of X and Y.

References

Examples

```python
>>> from sklearn.metrics.pairwise import nan_euclidean_distances
>>> nan = float("NaN")
>>> X = [[0, 1], [1, nan]]
>>> nan_euclidean_distances(X, X)  # distance between rows of X
array([[0., 1.41421356],
       [1.41421356, 0.]])

>>> # get distance to origin
>>> nan_euclidean_distances(X, [[0, 0]])
array([[1.],
       [1.41421356]])
```

**sklearn.metrics.pairwise.pairwise_kernels**

`sklearn.metrics.pairwise.pairwise_kernels(X, Y=None, metric='linear', filter_params=False, n_jobs=None, **kwds)`

Compute the kernel between arrays X and optional array Y.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise kernel between the arrays from both X and Y.

**Valid values for metric are:** ['additive_chi2', 'chi2', 'linear', 'poly', 'polynomial', 'rbf', 'laplacian', 'sigmoid', 'cosine']

Read more in the User Guide.

**Parameters**

- X [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise kernels between samples, or a feature array.
- Y [array [n_samples_b, n_features]] A second feature array only if X has shape [n_samples_a, n_features].
- metric [string, or callable] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is "precomputed", X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair
of instances (rows) and the resulting value recorded. The callable should take two rows from X as input and return the corresponding kernel value as a single number. This means that callables from sklearn.metrics.pairwise are not allowed, as they operate on matrices, not single samples. Use the string identifying the kernel instead.

**filter_params** [boolean] Whether to filter invalid parameters or not.

**n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**kwds** [optional keyword parameters] Any further parameters are passed directly to the kernel function.

Returns

K [array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]] A kernel matrix K such that K_{i, j} is the kernel between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then K_{i, j} is the kernel between the ith array from X and the jth array from Y.

Notes

If metric is ‘precomputed’, Y is ignored and X is returned.

**sklearn.metrics.pairwise.polynomial_kernel**

sklearn.metrics.pairwise.polynomial_kernel(X, Y=None, degree=3, gamma=None, coef0=1)

Compute the polynomial kernel between X and Y:

\[ K(X, Y) = (\gamma \langle X, Y \rangle + \text{coef0})^\text{degree} \]

Read more in the User Guide.

Parameters

- X [ndarray of shape (n_samples_1, n_features)]
- Y [ndarray of shape (n_samples_2, n_features)]
- degree [int, default 3]
- gamma [float, default None] if None, defaults to 1.0 / n_features
- coef0 [float, default 1]

Returns

Gram matrix [array of shape (n_samples_1, n_samples_2)]

**sklearn.metrics.pairwise.rbf_kernel**

sklearn.metrics.pairwise.rbf_kernel(X, Y=None, gamma=None)

Compute the rbf (gaussian) kernel between X and Y:

\[ K(X, Y) = \exp(-\gamma \|X - Y\|^2) \]

Notes

If metric is ‘precomputed’, Y is ignored and X is returned.
**sklearn.metrics.pairwise.sigmoid_kernel**

`sklearn.metrics.pairwise.sigmoid_kernel(X, Y=None, gamma=None, coef0=1)`

Compute the sigmoid kernel between X and Y:

\[ K(X, Y) = \tanh(\gamma X^T Y + \text{coef0}) \]

Read more in the *User Guide*.

**Parameters**

- **X** [array-like, shape (n_samples_1, n_features)]
- **Y** [array-like, shape (n_samples_2, n_features)]
- **gamma** [float, default None] If None, defaults to 1.0 / n_features
- **coef0** [float, default 1]

**Returns**

- **Gram matrix** [array of shape (n_samples_1, n_samples_2)]
**sklearn.metrics.pairwise.paired_manhattan_distances**

`sklearn.metrics.pairwise.paired_manhattan_distances(X, Y)`

Compute the L1 distances between the vectors in X and Y.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)]
- **Y** [array-like, shape (n_samples, n_features)]

**Returns**

- **distances** [ndarray (n_samples, )]

**sklearn.metrics.pairwise.paired_cosine_distances**

`sklearn.metrics.pairwise.paired_cosine_distances(X, Y)`

Computes the paired cosine distances between X and Y.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)]
- **Y** [array-like, shape (n_samples, n_features)]

**Returns**

- **distances** [ndarray, shape (n_samples, )]

**Notes**

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm.

**sklearn.metrics.pairwise.paired_distances**

`sklearn.metrics.pairwise.paired_distances(X, Y, metric='euclidean', **kwds)`

Computes the paired distances between X and Y.

Computes the distances between (X[0], Y[0]), (X[1], Y[1]), etc... etc...

Read more in the *User Guide*.

**Parameters**

- **X** [ndarray (n_samples, n_features)] Array 1 for distance computation.
- **Y** [ndarray (n_samples, n_features)] Array 2 for distance computation.
- **metric** [string or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options specified in PAIRED_DISTANCES, including “euclidean”, “manhattan”, or “cosine”. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.
Returns

distances [ndarray (n_samples, )]

See also:

pairwise_distances Computes the distance between every pair of samples

Examples

```python
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([[0., 1.]])
```

sklearn.metrics.pairwise_distances

sklearn.metrics.pairwise_distances(X, Y=None, metric='euclidean', n_jobs=None, force_all_finite=True, **kwds)

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector
array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many
other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X
and Y.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse
  matrix inputs. ['nan_euclidean'] but it does not yet support sparse matrices.

- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard',
  'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath',
  'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on
  these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid scipy.spatial.distance metrics),
the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock').
For a verbose description of the metrics from scikit-learn, see the __doc__ of the
sklearn.pairwise.distance_metrics function.

Read more in the User Guide.

Parameters

- X [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.

- Y [array [n_samples_b, n_features], optional] An optional second feature array. Only allowed
  if metric != “precomputed”.
**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

**n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**force_all_finite** [boolean or ‘allow-nan’, (default=True)] Whether to raise an error on np.inf and np.nan in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accept both np.inf and np.nan in array.
- ‘allow-nan’: accept only np.nan values in array. Values cannot be infinite.

New in version 0.22.

**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

**Returns**

D [array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]] A distance matrix D such that D_[i, j] is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_[i, j] is the distance between the ith array from X and the jth array from Y.

See also:

pairwise_distances_chunked performs the same calculation as this function, but returns a generator of chunks of the distance matrix, in order to limit memory usage.

paired_distances Computes the distances between corresponding elements of two arrays

**Examples using sklearn.metrics.pairwise_distances**

- Agglomerative clustering with different metrics

sklearn.metrics.pairwise_distances_argmin

sklearn.metrics.pairwise_distances_argmin(X, Y, axis=1, metric='euclidean', metric_kwarg=None)

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance).

This is mostly equivalent to calling:

pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)
This function works with dense 2D arrays only.

**Parameters**

- **X** [array-like] Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)
- **Y** [array-like] Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)
- **axis** [int, optional, default 1] Axis along which the argmin and distances are to be computed.
- **metric** [string or callable] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.
  
  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.
  
  Distance matrices are not supported.
  
  Valid values for metric are:
  
  - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
  
  See the documentation for scipy.spatial.distance for details on these metrics.

- **metric_kwargs** [dict] keyword arguments to pass to specified metric function.

**Returns**

- **argmin** [numpy.ndarray] Y[argmin[i], :] is the row in Y that is closest to X[i, :].

See also:

- `sklearn.metrics.pairwise_distances`
- `sklearn.metrics.pairwise_distances_argmin_min`

**Examples using sklearn.metrics.pairwise_distances_argmin**

- **Color Quantization using K-Means**
- **Comparison of the K-Means and MiniBatchKMeans clustering algorithms**

**sklearn.metrics.pairwise_distances_argmin_min**

```python
sklearn.metrics.pairwise_distances_argmin_min(X, Y, axis=1, metric='euclidean', metric_kwargs=None)
```

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance). The minimal distances are also returned.

This is mostly equivalent to calling:
but uses much less memory, and is faster for large arrays.

Parameters

- **X** (array-like, shape (n_samples1, n_features)) Array containing points.
- **Y** (array-like, shape (n_samples2, n_features)) Arrays containing points.
- **axis** (int, optional, default 1) Axis along which the argmin and distances are to be computed.
- **metric** (string or callable, default 'euclidean') metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

  Distance matrices are not supported.

  Valid values for metric are:

  - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

  See the documentation for scipy.spatial.distance for details on these metrics.

- **metric_kwargs** (dict, optional) Keyword arguments to pass to specified metric function.

Returns

- **argmin** (numpy.ndarray) Y[argmin[i],:] is the row in Y that is closest to X[i, :].
- **distances** (numpy.ndarray) distances[i] is the distance between the i-th row in X and the argmin[i]-th row in Y.

See also:

- `sklearn.metrics.pairwise_distances`
- `sklearn.metrics.pairwise_distances_argmin`

`sklearn.metrics.pairwise_distances_chunked`

Generate a distance matrix chunk by chunk with optional reduction.

In cases where not all of a pairwise distance matrix needs to be stored at once, this is used to calculate pairwise distances in working_memory-sized chunks. If reduce_func is given, it is run on each chunk and its return values are concatenated into lists, arrays or sparse matrices.

Parameters

- **X** (array [n_samples_a, n_samples_a] if metric == “precomputed”, or [n_samples_a, n_features] otherwise Array of pairwise distances between samples, or a feature array.
Y [array [n_samples_b, n_features], optional] An optional second feature array. Only allowed if metric != "precomputed".

reduce_func [callable, optional] The function which is applied on each chunk of the distance matrix, reducing it to needed values. reduce_func(D_chunk, start) is called repeatedly, where D_chunk is a contiguous vertical slice of the pairwise distance matrix, starting at row start. It should return an array, a list, or a sparse matrix of length D_chunk.shape[0], or a tuple of such objects.

If None, pairwise_distances_chunked returns a generator of vertical chunks of the distance matrix.

metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

working_memory [int, optional] The sought maximum memory for temporary distance matrix chunks. When None (default), the value of sklearn.get_config()['working_memory'] is used.

**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Yields

D_chunk [array or sparse matrix] A contiguous slice of distance matrix, optionally processed by reduce_func.

Examples

Without reduce_func:

```python
>>> import numpy as np
>>> from sklearn.metrics import pairwise_distances_chunked
>>> X = np.random.RandomState(0).rand(5, 3)
>>> D_chunk = next(pairwise_distances_chunked(X))
>>> D_chunk
array([[0. ..., 0.29..., 0.41..., 0.19..., 0.57...],
       [0.29..., 0. ..., 0.57..., 0.41..., 0.76...],
       [0.41..., 0.57..., 0. ..., 0.44..., 0.90...],
       [0.19..., 0.41..., 0.44..., 0. ..., 0.51...],
       [0.57..., 0.76..., 0.90..., 0.51..., 0. ...]])
```

Retrieve all neighbors and average distance within radius r:
```python
>>> r = .2
>>> def reduce_func(D_chunk, start):
...     neigh = [np.flatnonzero(d < r) for d in D_chunk]
...     avg_dist = (D_chunk * (D_chunk < r)).mean(axis=1)
...     return neigh, avg_dist

>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func)
>>> neigh, avg_dist = next(gen)
>>> neigh
[array([0, 3]), array([1]), array([2]), array([0, 3]), array([4])]
>>> avg_dist
array([0.039..., 0., 0., 0.039..., 0.])

Where r is defined per sample, we need to make use of start:

```python
>>> r = [.2, .4, .4, .3, .1]
>>> def reduce_func(D_chunk, start):
...     neigh = [np.flatnonzero(d < r[i]) for i, d in enumerate(D_chunk, start)]
...     return neigh

>>> neigh = next(pairwise_distances_chunked(X, reduce_func=reduce_func))
>>> neigh
[array([0, 3]), array([0, 1]), array([2]), array([0, 3]), array([4])]
```

Force row-by-row generation by reducing working_memory:

```python
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func,
...                                   working_memory=0)
>>> next(gen)
[array([0, 3])]
>>> next(gen)
[array([0, 1])]
```

### 7.24.8 Plotting

See the **Visualizations** section of the user guide for further details.

```python
metrics.plot_confusion_matrix(estimator, X, ...)  # Plot Confusion Matrix.
metrics.plot_precision_recall_curve(...)  # Plot Precision Recall Curve for binary classifiers.
metrics.plot_roc_curve(estimator, X, y[, ...])  # Plot Receiver operating characteristic (ROC) curve.
```

**sklearn.metrics.plot_confusion_matrix**

```python
sklearn.metrics.plot_confusion_matrix(estimator, X, y_true, labels=None, sample_weight=None, normalize=None, display_labels=None, include_values=True, xticks_rotation='horizontal', values_format=None, cmap='viridis', ax=None)
```

Plot Confusion Matrix.

Read more in the **User Guide**.
estimator  [estimator instance] Trained classifier.
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Input values.
y  [array-like of shape (n_samples,)] Target values.
labels  [array-like of shape (n_classes,), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If None is given, those that appear at least once in y_true or y_pred are used in sorted order.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.
normalize  [{‘true’, ‘pred’, ‘all’}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.
display_labels  [array-like of shape (n_classes,), default=None] Target names used for plotting. By default, labels will be used if it is defined, otherwise the unique labels of y_true and y_pred will be used.
include_values  [bool, default=True] Includes values in confusion matrix.
xticks_rotation  [{'vertical', 'horizontal'} or float, default='horizontal'] Rotation of xtick labels.
values_format  [str, default=None] Format specification for values in confusion matrix. If None, the format specification is ‘.2g’.
cmap  [str or matplotlib Colormap, default='viridis'] Colormap recognized by matplotlib.
ax  [matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

Returns  
display  [ConfusionMatrixDisplay]

Examples using sklearn.metrics.plot_confusion_matrix

- Recognizing hand-written digits
- Confusion matrix

sklearn.metrics.plot_precision_recall_curve

sklearn.metrics.plot_precision_recall_curve  (estimator,  X,  y,  sample_weight=None,
             response_method=’auto’,  name=None,
             ax=None,  **kwargs)

Plot Precision Recall Curve for binary classifiers.
Extra keyword arguments will be passed to matplotlib’s plot.
Read more in the User Guide.

Parameters

estimator  [estimator instance] Trained classifier.
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Input values.
y  [array-like of shape (n_samples,)] Binary target values.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.
**response_method** [{‘predict_proba’, ‘decision_function’, ‘auto’}, default=’auto’] Specifies whether to use predict_proba or decision_function as the target response. If set to ‘auto’, predict_proba is tried first and if it does not exist decision_function is tried next.

**name** [str, default=None] Name for labeling curve. If None, the name of the estimator is used.

**ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**kwargs** [dict] Keyword arguments to be passed to matplotlib’s plot.

Returns

**display** [PrecisionRecallDisplay] Object that stores computed values.

**Examples using sklearn.metrics.plot_precision_recall_curve**

- Precision-Recall

**sklearn.metrics.plot_roc_curve**

sklearn.metrics.plot_roc_curve (estimator, X, y, sample_weight=None, drop_intermediate=True, response_method=’auto’, name=None, ax=None, **kwargs)

Plot Receiver operating characteristic (ROC) curve.

Extra keyword operating characteristic (ROC) curve.

Read more in the User Guide.

**Parameters**

**estimator** [estimator instance] Trained classifier.

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Input values.

**y** [array-like of shape (n_samples,)] Target values.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**drop_intermediate** [boolean, default=True] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

**response_method** [{‘predict_proba’, ‘decision_function’, ‘auto’}, default=’auto’] Specifies whether to use predict_proba or decision_function as the target response. If set to ‘auto’, predict_proba is tried first and if it does not exist decision_function is tried next.

**name** [str, default=None] Name of ROC Curve for labeling. If None, use the name of the estimator.

**ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

Returns

**display** [RocCurveDisplay] Object that stores computed values.
Examples

```python
>>> import matplotlib.pyplot as plt
# doctest: +SKIP
>>> from sklearn import datasets, metrics, model_selection, svm
>>> X, y = datasets.make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = model_selection.train_test_split(
    X, y, random_state=0)
>>> clf = svm.SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> metrics.plot_roc_curve(clf, X_test, y_test)  # doctest: +SKIP
>>> plt.show()  # doctest: +SKIP
```

Examples using `sklearn.metrics.plot_roc_curve`

- ROC Curve with Visualization API
- Receiver Operating Characteristic (ROC) with cross validation
- Release Highlights for scikit-learn 0.22

```
metrics.ConfusionMatrixDisplay(...)
Confusion Matrix visualization.
metrics.PrecisionRecallDisplay(precision, ...
Precision Recall visualization.
metrics.RocCurveDisplay(fpr, tpr, roc_auc, ...
ROC Curve visualization.
```

`sklearn.metrics.ConfusionMatrixDisplay`

class `sklearn.metrics.ConfusionMatrixDisplay`(confusion_matrix, display_labels)

Confusion Matrix visualization.

It is recommend to use `plot_confusion_matrix` to create a `ConfusionMatrixDisplay`. All parameters are stored as attributes.

Read more in the User Guide.

Parameters

- **confusion_matrix** [ndarray of shape (n_classes, n_classes)] Confusion matrix.
- **display_labels** [ndarray of shape (n_classes,)] Display labels for plot.

Attributes

- **im** [matplotlib AxesImage] Image representing the confusion matrix.
- **text** [ndarray of shape (n_classes, n_classes), dtype=matplotlib Text, or None] Array of matplotlib axes. None if include_values is false.
- **ax** [matplotlib Axes] Axes with confusion matrix.
- **figure** [matplotlib Figure] Figure containing the confusion matrix.

Methods
plot(self[, include_values, cmap, ...])  Plot visualization.

_init_(self, confusion_matrix, display_labels)  
Initialize self. See help(type(self)) for accurate signature.

plot (self, include_values=True, cmap='viridis', xticks_rotation='horizontal', values_format=None, ax=None)  
Plot visualization.

Parameters

include_values [bool, default=True] Includes values in confusion matrix.
cmap [str or matplotlib Colormap, default='viridis'] Colormap recognized by matplotlib.
xticks_rotation [{'vertical', 'horizontal'} or float, default='horizontal'] Rotation of xtick labels.
values_format [str, default=None] Format specification for values in confusion matrix. If None, the format specification is '.2g'.
ax [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

Returns

display [ConfusionMatrixDisplay]

sklearn.metrics.PrecisionRecallDisplay

class sklearn.metrics.PrecisionRecallDisplay (precision, recall, average_precision, estimator_name)  

Precision Recall visualization.

It is recommend to use plot_precision_recall_curve to create a visualizer. All parameters are stored as attributes.

Read more in the User Guide.

Parameters

precision [ndarray] Precision values.
recall [ndarray] Recall values.
average_precision [float] Average precision.
estimator_name [str] Name of estimator.

Attributes

line_ [matplotlib Artist] Precision recall curve.
ax_ [matplotlib Axes] Axes with precision recall curve.
figure_ [matplotlib Figure] Figure containing the curve.

Methods

plot(self, ax, name)  Plot visualization.
__init__(self, precision, recall, average_precision, estimator_name)
Initialize self. See help(type(self)) for accurate signature.

plot(self, ax=None, name=None, **kwargs)
Plot visualization.
Extra keyword arguments will be passed to matplotlib's plot.

Parameters

ax [Matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.
name [str, default=None] Name of precision recall curve for labeling. If None, use the name of the estimator.
**kwargs [dict] Keyword arguments to be passed to matplotlib's plot.

Returns
display [PrecisionRecallDisplay] Object that stores computed values.

sklearn.metrics.RocCurveDisplay
class sklearn.metrics.RocCurveDisplay(fpr, tpr, roc_auc, estimator_name)
ROC Curve visualization.
It is recommend to use plot_roc_curve to create a visualizer. All parameters are stored as attributes.
Read more in the User Guide.

Parameters

fpr [ndarray] False positive rate.
tpr [ndarray] True positive rate.
roc_auc [float] Area under ROC curve.
estimator_name [str] Name of estimator.

Attributes

line_ [matplotlib Artist] ROC Curve.
ax_ [matplotlib Axes] Axes with ROC Curve.
figure_ [matplotlib Figure] Figure containing the curve.

Examples

```python
>>> import matplotlib.pyplot as plt  # doctest: +SKIP
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([0, 0, 1, 1])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred)
>>> roc_auc = metrics.auc(fpr, tpr)
>>> display = metrics.RocCurveDisplay(fpr=fpr, tpr=tpr, roc_auc=roc_auc,
... estimator_name='example estimator')
>>> display.plot()  # doctest: +SKIP
>>> plt.show()  # doctest: +SKIP
```
Methods

plot(self[, ax, name])  
Plot visualization

__init__(self, fpr, tpr, roc_auc, estimator_name)  
Initialize self. See help(type(self)) for accurate signature.

plot (self, ax=None, name=None, **kwargs)  
Plot visualization  
Extra keyword arguments will be passed to matplotlib’s plot.

Parameters

ax [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

name [str, default=None] Name of ROC Curve for labeling. If None, use the name of the estimator.

Returns

display [RocCurveDisplay] Object that stores computed values.

7.25 sklearn.mixture: Gaussian Mixture Models

The sklearn.mixture module implements mixture modeling algorithms.

User guide: See the Gaussian mixture models section for further details.

mixture.BayesianGaussianMixture([...])  
Variational Bayesian estimation of a Gaussian mixture.

mixture.GaussianMixture([n_components, ...])  
Gaussian Mixture.

7.25.1 sklearn.mixture.BayesianGaussianMixture

class sklearn.mixture.BayesianGaussianMixture (n_components=1,  
covariance_type='full', tol=0.001,  
reg_covar=1e-06, max_iter=100,  
n_init=1, init_params='kmeans',  
weight_concentration_prior_type='dirichlet_process',  
weight_concentration_prior=None,  
mean_precision_prior=None,  
mean_prior=None,  
degrees_of_freedom_prior=None, covariance_prior=None,  
random_state=None,  
warm_start=False, verbose=0, verbose_interval=10)  
Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference
algorithm is approximated and uses a truncated distribution with a fixed maximum number of components (called the Stick-breaking representation). The number of components actually used almost always depends on the data.

New in version 0.18.

Read more in the User Guide.

Parameters

- `n_components` [int, defaults to 1.] The number of mixture components. Depending on the data and the value of the `weight_concentration_prior` the model can decide to not use all the components by setting some component `weights_` to values very close to zero. The number of effective components is therefore smaller than `n_components`.

- `covariance_type` [{‘full’, ‘tied’, ‘diag’, ‘spherical’}, defaults to ‘full’] String describing the type of covariance parameters to use. Must be one of:

  - ‘full’ (each component has its own general covariance matrix),
  - ‘tied’ (all components share the same general covariance matrix),
  - ‘diag’ (each component has its own diagonal covariance matrix),
  - ‘spherical’ (each component has its own single variance).

- `tol` [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

- `reg_covar` [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

- `max_iter` [int, defaults to 100.] The number of EM iterations to perform.

- `n_init` [int, defaults to 1.] The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

- `init_params` [{‘kmeans’, ‘random’}, defaults to ‘kmeans’] The method used to initialize the weights, the means and the covariances. Must be one of:

  - ‘kmeans’ : responsibilities are initialized using kmeans.
  - ‘random’ : responsibilities are initialized randomly.

- `weight_concentration_prior_type` [str, defaults to ‘dirichlet_process’] String describing the type of the weight concentration prior. Must be one of:

  - ‘dirichlet_process’ (using the Stick-breaking representation),
  - ‘dirichlet_distribution’ (can favor more uniform weights).

- `weight_concentration_prior` [float | None, optional.] The dirichlet concentration of each component on the weight distribution (Dirichlet). This is commonly called gamma in the literature. The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it’s set to \(1 / n_{\text{components}}\).

- `mean_precision_prior` [float | None, optional] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around `mean_prior`. The value of the parameter must be greater than 0. If it is None, it is set to 1.

- `mean_prior` [array-like, shape (n_features,), optional] The prior on the mean distribution (Gaussian). If it is None, it is set to the mean of X.
degrees_of_freedom_prior [float | None, optional.] The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it’s set to n_features.

covariance_prior [float or array-like, optional] The prior on the covariance distribution (Wishart). If it is None, the empirical covariance prior is initialized using the covariance of X. The shape depends on covariance_type:

\[
\begin{align*}
(n_{\text{features}}, n_{\text{features}}) & \text{ if 'full',} \\
(n_{\text{features}}, n_{\text{features}}) & \text{ if 'tied',} \\
(n_{\text{features}}) & \text{ if 'diag',} \\
\text{float} & \text{ if 'spherical'}
\end{align*}
\]

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

warm_start [bool, default to False.] If ‘warm_start’ is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several times on similar problems. See the Glossary.

verbose [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

verbose_interval [int, default to 10.] Number of iteration done before the next print.

Attributes

weights_ [array-like, shape (n_components,)] The weights of each mixture components.

means_ [array-like, shape (n_components, n_features)] The mean of each mixture component.

covariances_ [array-like] The covariance of each mixture component. The shape depends on covariance_type:

\[
\begin{align*}
(n_{\text{components}},) & \text{ if 'spherical',} \\
(n_{\text{features}}, n_{\text{features}}) & \text{ if 'tied',} \\
(n_{\text{components}}, n_{\text{features}}) & \text{ if 'diag',} \\
(n_{\text{components}}, n_{\text{features}}, n_{\text{features}}) & \text{ if 'full'}
\end{align*}
\]

precisions_ [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

\[
\begin{align*}
(n_{\text{components}},) & \text{ if 'spherical',} \\
(n_{\text{features}}, n_{\text{features}}) & \text{ if 'tied',} \\
(n_{\text{components}}, n_{\text{features}}) & \text{ if 'diag',} \\
(n_{\text{components}}, n_{\text{features}}, n_{\text{features}}) & \text{ if 'full'}
\end{align*}
\]

precisions_cholesky_ [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:
converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of inference to reach the convergence.

lower_bound_ [float] Lower bound value on the likelihood (of the training data with respect to
the model) of the best fit of inference.

weight_concentration_prior_ [tuple or float] The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on weight_concentration_prior_type:

*(float, float)* if 'dirichlet_process' (Beta parameters),
*float* if 'dirichlet_distribution' (Dirichlet parameters).*

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the simplex.

weight_concentration_ [array-like, shape (n_components,)] The dirichlet concentration of each component on the weight distribution (Dirichlet).

mean_precision_prior_ [float] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around mean_prior. If mean_precision_prior is set to None, mean_precision_prior_ is set to 1.

mean_precision_ [array-like, shape (n_components,)] The precision of each components on the mean distribution (Gaussian).

mean_prior_ [array-like, shape (n_features,)] The prior on the mean distribution (Gaussian).

degrees_of_freedom_prior_ [float] The prior of the number of degrees of freedom on the covariance distributions (Wishart).

degrees_of_freedom_ [array-like, shape (n_components,)] The number of degrees of freedom of each components in the model.

covariance_prior_ [float or array-like] The prior on the covariance distribution (Wishart). The shape depends on covariance_type:

*(n_features, n_features)* if 'full',
*(n_features, n_features)* if 'tied',
*(n_features)* if 'diag',
*float* if 'spherical'*

__init__ (self, n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weight_concentration_prior_type='dirichlet_process', weight_concentration_prior=None, mean_precision_prior=None, mean_prior=None, degrees_of_freedom_prior=None, covariance_prior=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)

Estimate model parameters with the EM algorithm.

The method fits the model n_init times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised. If warm_start is True, then n_init is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

self

fit_predict (self, X, y=None)

Estimate model parameters using X and predict the labels for X.

The method fits the model n_init times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
Returns

labels [array, shape (n_samples,)] Component labels.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict the labels for the data samples in X using trained model.

Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

labels [array, shape (n_samples,)] Component labels.

predict_proba (self, X)
Predict posterior probability of each component given the data.

Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

resp [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

sample (self, n_samples=1)
Generate random samples from the fitted Gaussian distribution.

Parameters

n_samples [int, optional] Number of samples to generate. Defaults to 1.

Returns

X [array, shape (n_samples, n_features)] Randomly generated sample
y [array, shape (n_samples,)] Component labels

score (self, X, y=None)
Compute the per-sample average log-likelihood of the given data X.

Parameters

X [array-like, shape (n_samples, n_dimensions)] List of n_dimensions-dimensional data points. Each row corresponds to a single data point.

Returns

log_likelihood [float] Log likelihood of the Gaussian mixture given X.

score_samples (self, X)
Compute the weighted log probabilities for each sample.
Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

log_prob [array, shape (n_samples,)] Log probabilities of each data point in X.

set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.mixture.BayesianGaussianMixture

- Gaussian Mixture Model Ellipsoids
- Gaussian Mixture Model Sine Curve
- Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture

7.25.2 sklearn.mixture.GaussianMixture

class sklearn.mixture.GaussianMixture(n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weights_init=None, means_init=None, precisions_init=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)

Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

Read more in the User Guide.

New in version 0.18.

Parameters

n_components [int, defaults to 1.] The number of mixture components.

covariance_type [‘full’ (default), ‘tied’, ‘diag’, ‘spherical’] String describing the type of covariance parameters to use. Must be one of:

‘full’ each component has its own general covariance matrix
‘tied’ all components share the same general covariance matrix
‘diag’ each component has its own diagonal covariance matrix
‘spherical’ each component has its own single variance

7.25. sklearn.mixture: Gaussian Mixture Models 2211
tol [float, defaults to 1e-3. ] The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.

reg_covar [float, defaults to 1e-6. ] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

max_iter [int, defaults to 100. ] The number of EM iterations to perform.

n_init [int, defaults to 1. ] The number of initializations to perform. The best results are kept.

init_params [’kmeans’, ‘random’], defaults to ’kmeans’. ] The method used to initialize the weights, the means and the precisions. Must be one of:

<table>
<thead>
<tr>
<th>init_params</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'kmeans' : responsibilities are initialized using kmeans.</td>
<td></td>
</tr>
<tr>
<td>'random' : responsibilities are initialized randomly.</td>
<td></td>
</tr>
</tbody>
</table>

weights_init [array-like, shape (n_components, ), optional] The user-provided initial weights, defaults to None. If it None, weights are initialized using the init_params method.

means_init [array-like, shape (n_components, n_features), optional] The user-provided initial means, defaults to None. If it None, means are initialized using the init_params method.

precisions_init [array-like, optional. ] The user-provided initial precisions (inverse of the covariance matrices), defaults to None. If it None, precisions are initialized using the ‘init_params’ method. The shape depends on ‘covariance_type’:

<table>
<thead>
<tr>
<th>covariance_type</th>
<th>Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>spherical'</td>
<td>(n_components, )</td>
</tr>
<tr>
<td>tied'</td>
<td>(n_features, n_features)</td>
</tr>
<tr>
<td>diag'</td>
<td>(n_components, n_features)</td>
</tr>
<tr>
<td>full'</td>
<td>(n_components, n_features, n_features)</td>
</tr>
</tbody>
</table>

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

warm_start [bool, default to False. ] If ‘warm_start’ is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several times on similar problems. In that case, ‘n_init’ is ignored and only a single initialization occurs upon the first call. See the Glossary.

verbose [int, default to 0. ] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

verbose_interval [int, default to 10. ] Number of iteration done before the next print.

Attributes

weights_ [array-like, shape (n_components,)] The weights of each mixture components.

means_ [array-like, shape (n_components, n_features)] The mean of each mixture component.

covariances_ [array-like] The covariance of each mixture component. The shape depends on covariance_type:

<table>
<thead>
<tr>
<th>covariance_type</th>
<th>Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>spherical'</td>
<td>(n_components, )</td>
</tr>
<tr>
<td>tied'</td>
<td>(n_features, n_features)</td>
</tr>
<tr>
<td>diag'</td>
<td>(n_components, n_features)</td>
</tr>
<tr>
<td>full'</td>
<td>(n_components, n_features, n_features)</td>
</tr>
</tbody>
</table>
precisions_ [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

\[
\begin{align*}
\text{(n_components,)} & \quad \text{if 'spherical'}, \\
\text{(n_features, n_features)} & \quad \text{if 'tied'}, \\
\text{(n_components, n_features)} & \quad \text{if 'diag'}, \\
\text{(n_components, n_features, n_features)} & \quad \text{if 'full'}
\end{align*}
\]

precisions_cholesky_ [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

\[
\begin{align*}
\text{(n_components,)} & \quad \text{if 'spherical'}, \\
\text{(n_features, n_features)} & \quad \text{if 'tied'}, \\
\text{(n_components, n_features)} & \quad \text{if 'diag'}, \\
\text{(n_components, n_features, n_features)} & \quad \text{if 'full'}
\end{align*}
\]

converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of EM to reach the convergence.

lower_bound_ [float] Lower bound value on the log-likelihood (of the training data with respect to the model) of the best fit of EM.

See also:

**BayesianGaussianMixture** Gaussian mixture model fit with a variational inference.

Methods

- `aic(self, X)` Akaike information criterion for the current model on the input X.
- `bic(self, X)` Bayesian information criterion for the current model on the input X.
- `fit(self, X[, y])` Estimate model parameters with the EM algorithm.
- `fit_predict(self, X[, y])` Estimate model parameters using X and predict the labels for X.
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, X)` Predict the labels for the data samples in X using trained model.
- `predict_proba(self, X)` Predict posterior probability of each component given the data.
- `sample(self[, n_samples])` Generate random samples from the fitted Gaussian distribution.
- `score(self, X[, y])` Compute the per-sample average log-likelihood of the given data X.

</tbody>
</table>

```python
__init__(self, n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weights_init=None, means_init=None, precisions_init=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)
```

Initialize self. See help(type(self)) for accurate signature.

```python
aic(self, X)
```

Akaike information criterion for the current model on the input X.

**Parameters**

- `X` [array of shape (n_samples, n_dimensions)]

**Returns**

- `aic` [float] The lower the better.

```python
bic(self, X)
```

Bayesian information criterion for the current model on the input X.

**Parameters**

- `X` [array of shape (n_samples, n_dimensions)]

**Returns**

- `bic` [float] The lower the better.

```python
fit(self, X, y=None)
```

Estimate model parameters using the EM algorithm.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. If `warm_start` is True, then `n_init` is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- `self`

```python
fit_predict(self, X, y=None)
```

Estimate model parameters using X and predict the labels for X.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

**Parameters**
**X** [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

labels [array, shape (n_samples,)] Component labels.

**get_params** (*self*, *deep=True*)
Get parameters for this estimator.

**Parameters**

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)
Predict the labels for the data samples in X using trained model.

**Parameters**

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

labels [array, shape (n_samples,)] Component labels.

**predict_proba** (*self*, *X*)
Predict posterior probability of each component given the data.

**Parameters**

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

resp [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** (*self*, *n_samples=1*)
Generate random samples from the fitted Gaussian distribution.

**Parameters**

n_samples [int, optional] Number of samples to generate. Defaults to 1.

**Returns**

X [array, shape (n_samples, n_features)] Randomly generated sample

y [array, shape (n_samples,)] Component labels

**score** (*self*, *X, y=None*)
Compute the per-sample average log-likelihood of the given data X.

**Parameters**

X [array-like, shape (n_samples, n_dimensions)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

log_likelihood [float] Log likelihood of the Gaussian mixture given X.
**score_samples** *(self, X)*

Compute the weighted log probabilities for each sample.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **log_prob** [array, shape (n_samples,)] Log probabilities of each data point in X.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**Examples using sklearn.mixture.GaussianMixture**

- Comparing different clustering algorithms on toy datasets
- Density Estimation for a Gaussian mixture
- Gaussian Mixture Model Ellipsoids
- Gaussian Mixture Model Selection
- GMM covariances
- Gaussian Mixture Model Sine Curve

### sklearn.model_selection.GroupKFold

**class sklearn.model_selection.GroupKFold(n_splits=5)**

K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same in each fold.

**Parameters**

- **n_splits** [int, default=5] Number of folds. Must be at least 2.

  Changed in version 0.22: n_splits default value changed from 3 to 5.

**Examples**

```python
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
...     print("TRAIN: ", train_index, "TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
```

__init__

```
__init__(self, n_splits=5)
```

Initialize self. See help(type(self)) for accurate signature.

**get_n_splits**

```
get_n_splits(self[, X, y, groups])
```

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split**

```
split(self, X[, y, groups])
```

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape (n_samples,), optional] The target variable for supervised learning problems.
- **groups** [array-like, with shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

**Examples using sklearn.model_selection.GroupKFold**

- Visualizing cross-validation behavior in scikit-learn
**sklearn.model_selection.GroupShuffleSplit**

**class** sklearn.model_selection.GroupShuffleSplit(n_splits=5, test_size=None, train_size=None, random_state=None)

Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and GroupShuffleSplit is that the former generates splits using all subsets of size \( p \) unique groups, whereas GroupShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to LeavePGroupsOut (\( p=10 \)) would be GroupShuffleSplit (test_size=10, n_splits=100).

Note: The parameters test_size and train_size refer to groups, and not to samples, as in ShuffleSplit.

**Parameters**

- **n_splits** [int (default 5)] Number of re-shuffling & splitting iterations.
- **test_size** [float, int, None, optional (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of groups to include in the test split (rounded up). If int, represents the absolute number of test groups. If None, the value is set to the complement of the train size. By default, the value is set to 0.2. The default will change in version 0.21. It will remain 0.2 only if train_size is unspecified, otherwise it will complement the specified train_size.
- **train_size** [float, int, or None, default is None] If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import GroupShuffleSplit
>>> X = np.ones(shape=(8, 2))
>>> y = np.ones(shape=(8, 1))
>>> groups = np.array([1, 1, 2, 2, 2, 3, 3, 3])
>>> print(groups.shape)
(8,)
>>> gss = GroupShuffleSplit(n_splits=2, train_size=.7, random_state=42)
>>> gss.get_n_splits()
2
>>> for train_idx, test_idx in gss.split(X, y, groups):
...     print("TRAIN:", train_idx, "TEST:", test_idx)
TRAIN: [2 3 4 5 6 7] TEST: [0 1]
TRAIN: [0 1 5 6 7] TEST: [2 3 4]
```
Methods

__init__(self, n_splits=5, test_size=None, train_size=None, random_state=None)
Initializes self. See help(type(self)) for accurate signature.

get_n_splits(self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator.

Parameters

X [object] Always ignored, exists for compatibility.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split(self, X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples,), optional] The target variable for supervised learning problems.
groups [array-like, with shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.GroupShuffleSplit

- Visualizing cross-validation behavior in scikit-learn
sklearn.model_selection.KFold

class sklearn.model_selection.KFold(n_splits=5, shuffle=False, random_state=None)

K-Folds cross-validator

Provides train/test indices to split data in train/test sets. Split dataset into \textit{k} consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the \textit{k} - 1 remaining folds form the training set.

Read more in the \textit{User Guide}.

Parameters

\textbf{n\_splits} \ [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: \textbf{n\_splits} default value changed from 3 to 5.

\textbf{shuffle} \ [boolean, optional] Whether to shuffle the data before splitting into batches.

\textbf{random\_state} \ [int, RandomState instance or None, optional, default=None] If int, \textbf{random\_state} is the seed used by the random number generator; If RandomState instance, \textbf{random\_state} is the random number generator; If None, the random number generator is the RandomState instance used by \textit{np.random}. Only used when \textbf{shuffle} is True. This should be left to None if \textbf{shuffle} is False.

See also:

\textit{StratifiedKFold} Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).

\textit{GroupKFold} K-fold iterator variant with non-overlapping groups.

\textit{RepeatedKFold} Repeats K-Fold \textit{n} times.

Notes

The first \textit{n\_samples} \% \textbf{n\_splits} folds have size \textit{n\_samples} / \textbf{n\_splits} + 1, other folds have size \textit{n\_samples} / \textbf{n\_splits}, where \textit{n\_samples} is the number of samples.

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting \textbf{random\_state} to an integer.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
```
Methods

__init__ (self, n_splits=5, shuffle=False, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

get_n_splits (self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters

- X [object] Always ignored, exists for compatibility.
- y [object] Always ignored, exists for compatibility.
- groups [object] Always ignored, exists for compatibility.

Returns

- n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (self, X=None, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

- X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- y [array-like, shape (n_samples,)] The target variable for supervised learning problems.
- groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Yields

- train [ndarray] The training set indices for that split.
- test [ndarray] The testing set indices for that split.

Examples using sklearn.model_selection.KFold

- Feature agglomeration vs. univariate selection
- Gradient Boosting Out-of-Bag estimates
- Nested versus non-nested cross-validation
- Visualizing cross-validation behavior in scikit-learn
- Cross-validation on diabetes Dataset Exercise
sklearn.model_selection.LeaveOneGroupOut

class sklearn.model_selection.LeaveOneGroupOut

Leave One Group Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the User Guide.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneGroupOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
>>> logo = LeaveOneGroupOut()
>>> logo.get_n_splits(X, y, groups)
2
>>> logo.get_n_splits(groups=groups)  # 'groups' is always required
2
>>> print(logo)
LeaveOneGroupOut()
>>> for train_index, test_index in logo.split(X, y, groups):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [1 2]
```

Methods

- **get_n_splits**(self, X=None, y=None, groups=None)
  Returns the number of splitting iterations in the cross-validator

- **split**(self, X, y, groups=None)
  Generate indices to split data into training and test set.

- **__init__**(self, /, *args, **kwargs)
  Initialize self. See help(type(self)) for accurate signature.

- **get_n_splits**(self, X=None, y=None, groups=None)
  Returns the number of splitting iterations in the cross-validator

Parameters
**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [array-like, with shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

**Returns**

**n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** *(self, X, y=None, groups=None)*

Generate indices to split data into training and test set.

**Parameters**

**X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**y** [array-like, of length n_samples, optional] The target variable for supervised learning problems.

**groups** [array-like, with shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

---

**sklearn.model_selection.LeavePGroupsOut**

**class** *sklearn.model_selection.LeavePGroupsOut*(n_groups)*

Leave P Group(s) Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with all the samples assigned to \( p \) different values of the groups while the latter uses samples all assigned the same groups.

Read more in the *User Guide*.

**Parameters**

**n_groups** [int] Number of groups \( (p) \) to leave out in the test split.

**See also:**

*GroupKFold* K-fold iterator variant with non-overlapping groups.

**Examples**
```python
>>> import numpy as np
>>> from sklearn.model_selection import LeavePGroupsOut

>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups)  # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
...    print("TRAIN: ", train_index, " TEST: ", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6] [1 2] [3 4] [1 2] [5 6]] [[1 2] [3 4] [1 2] [2 1] [1 2]]
TRAIN: [1] TEST: [0 2]
[[3 4] [1 2] [5 6] [2] [1 1] [1 2] [5 6] [1] [2 1]]
TRAIN: [0] TEST: [1 2]
[[1 2] [3 4] [5 6]]
```

### Methods

- **get_n_splits**
  - Parameters:
    - `self`:
    - `X` [object]: Always ignored, exists for compatibility.
    - `y` [object]: Always ignored, exists for compatibility.
    - `groups` [array-like, with shape (n_samples, )]: Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.
  - Returns:
    - `n_splits` [int]: Returns the number of splitting iterations in the cross-validator.

- **split**
  - Parameters:
    - `self`:
    - `X` [object]: Always ignored, exists for compatibility.
    - `y` [object]: Always ignored, exists for compatibility.
    - `groups` [array-like, with shape (n_samples, )]: Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.
  - Returns:
    - `train_index` [list]: Returns the number of splitting iterations in the cross-validator.
    - `test_index` [list]: Generate indices to split data into training and test set.
X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like, of length n_samples, optional] The target variable for supervised learning problems.

groups [array-like, with shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.LeaveOneOut

class sklearn.model_selection.LeaveOneOut

Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: LeaveOneOut() is equivalent to KFold(n_splits=n) and LeavePOut(p=1) where n is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor KFold, ShuffleSplit or StratifiedKFold.

Read more in the User Guide.

See also:

LeaveOneGroupOut For splitting the data according to explicit, domain-specific stratification of the dataset.

GroupKFold K-fold iterator variant with non-overlapping groups.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneOut
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = LeaveOneOut()
>>> loo.get_n_splits(X)
2
>>> print(loo)
LeaveOneOut()

>>> for train_index, test_index in loo.split(X):
...     print("TRAIN: ", train_index, "TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [0] TEST: [0] [[3 4]] [[1 2]] [1] [2]
TRAIN: [0] TEST: [1] [[1 2]] [[3 4]] [1] [2]
```
Methods

<table>
<thead>
<tr>
<th>get_n_splits(slef, X[, y, groups])</th>
<th>Returns the number of splitting iterations in the cross-validator</th>
</tr>
</thead>
<tbody>
<tr>
<td>split(slef, X[, y, groups])</td>
<td>Generate indices to split data into training and test set.</td>
</tr>
</tbody>
</table>

__init__ (self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

get_n_splits (self, X, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters
X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns
n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (self, X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters
X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like, of length n_samples] The target variable for supervised learning problems.
groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Yields
train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

sklearn.model_selection.LeavePOut

class sklearn.model_selection.LeavePOut (p)
Leave-P-Out cross-validator

Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

Note: LeavePOut (p) is NOT equivalent to KFold (n_splits=n_samples // p) which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross-validation method can be very costly. For large datasets one should favor KFold, StratifiedKFold or ShuffleSplit.

Read more in the User Guide.
Parameters

\( p \) [int] Size of the test sets. Must be strictly less than the number of samples.

Examples

```python
generated text
```

Methods

```
generated text
```

__init__ (self, \( p \))
Initialize self. See help(type(self)) for accurate signature.

generated text

get_n_splits (self, X\[, y, groups\])
Returns the number of splitting iterations in the cross-validator

split (self, X\[, y, groups\])
Generate indices to split data into training and test set.

Parameters

\( X \) [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

\( y \) [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

split (self, \( X, y=None, groups=None \))
Generate indices to split data into training and test set.

Parameters

\( X \) [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

\( y \) [array-like, of length n_samples] The target variable for supervised learning problems.
groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.PredefinedSplit

class sklearn.model_selection.PredefinedSplit (test_fold)

Predefined split cross-validator

Provides train/test indices to split data into train/test sets using a predefined scheme specified by the user with the test_fold parameter.

Read more in the User Guide.

New in version 0.16.

Parameters

test_fold [array-like, shape (n_samples,)] The entry test_fold[i] represents the index of the test set that sample i belongs to. It is possible to exclude sample i from any test set (i.e. include sample i in every training set) by setting test_fold[i] equal to -1.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> print(ps.get_n_splits())
2
>>> print(ps)
PredefinedSplit(test_fold=array([ 0, 1, -1, 1]))
>>> for train_index, test_index in ps.split():
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
```

Methods

- `get_n_splits(self, X, y, groups)` Returns the number of splitting iterations in the cross-validator.
- `split(self, X, y, groups)` Generate indices to split data into training and test set.

__init__(self, test_fold)

Initialize self. See help(type(self)) for accurate signature.
get_n_splits (self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters

X [object] Always ignored, exists for compatibility.

y [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (self, X=None, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [object] Always ignored, exists for compatibility.

y [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.RepeatedKFold

class sklearn.model_selection.RepeatedKFold (n_splits=5, n_repeats=10, random_state=None)
Repeated K-Fold cross validator.
Repeats K-Fold n times with different randomization in each repetition.
Read more in the User Guide.

Parameters

n_splits [int, default=5] Number of folds. Must be at least 2.

n_repeats [int, default=10] Number of times cross-validator needs to be repeated.

random_state [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

See also:

RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.
Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     TRAIN: [0 1] TEST: [2 3]
     TRAIN: [2 3] TEST: [0 1]
     TRAIN: [1 2] TEST: [0 3]
     TRAIN: [0 3] TEST: [1 2]
```

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

</tr>
</tbody>
</table>

`__init__`(self, n_splits=5, n_repeats=10, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

`get_n_splits(self, X=None, y=None, groups=None)`: Returns the number of splitting iterations in the cross-validator.

Parameters

- **X** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- **y** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split(self, X=None, y=None, groups=None)`: Generates indices to split data into training and test set.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, of length n_samples] The target variable for supervised learning problems.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Yields
train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.RepeatedStratifiedKFold

class sklearn.model_selection.RepeatedStratifiedKFold(n_splits=5, n_repeats=10,
random_state=None)

Repeated Stratified K-Fold cross validator.
Repeats Stratified K-Fold n times with different randomization in each repetition.
Read more in the User Guide.

Parameters

- n_splits [int, default=5] Number of folds. Must be at least 2.
- n_repeats [int, default=10] Number of times cross-validator needs to be repeated.
- random_state [None, int or RandomState, default=None] Random state to be used to generate random state for each repetition.

See also:

RepeatedKFold Repeats K-Fold n times.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2,
... random_state=36851234)
>>> for train_index, test_index in rskf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

Methods

- `get_n_splits(self, X, y, groups)`: Returns the number of splitting iterations in the cross-validator
**Table 213 – continued from previous page**

### `split(self, X[, y, groups])`
Generates indices to split data into training and test set.

---

__init__ (self, n_splits=5, n_repeats=10, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

get_n_splits (self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility. np.zeros(n_samples) may be used as a placeholder.
- **y** [object] Always ignored, exists for compatibility. np.zeros(n_samples) may be used as a placeholder.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

split (self, X, y=None, groups=None)
Generates indices to split data into training and test set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, of length n_samples] The target variable for supervised learning problems.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

**sklearn.model_selection.ShuffleSplit**

**class sklearn.model_selection.ShuffleSplit (n_splits=10, test_size=None, train_size=None, random_state=None)**
Random permutation cross-validator

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the [User Guide](#).

**Parameters**

- **n_splits** [int, default 10] Number of re-shuffling & splitting iterations.
- **test_size** [float, int, None, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute...
number of test samples. If None, the value is set to the complement of the train size. If 
train_size is also None, it will be set to 0.1.

train_size [float, int, or None, default=None] If float, should be between 0.0 and 1.0 and repre-
sent the proportion of the dataset to include in the train split. If int, represents the absolute 
number of train samples. If None, the value is automatically set to the complement of the 
test size.

random_state [int, RandomState instance or None, optional (default=None)] If int, ran-
dom_state is the seed used by the random number generator; If RandomState instance, 
random_state is the random number generator; If None, the random number generator is 
the RandomState instance used by np.random.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=5, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
5
>>> print(rs)
ShuffleSplit(n_splits=5, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0 4] TEST: [5 2]
TRAIN: [4 0 2 5] TEST: [1 3]
TRAIN: [1 2 4 0] TEST: [3 5]
TRAIN: [3 4 1 0] TEST: [5 2]
TRAIN: [3 5 1 0] TEST: [2 4]
```

Methods

- `get_n_splits(self, X=None, y=None, groups=None)` Returns the number of splitting iterations in the cross-validator

- `split(self, X=None, y=None, groups=None)` Generate indices to split data into training and test set.

__init__ (self, n_splits=10, test_size=None, train_size=None, random_state=None) 
Initialize self. See help(type(self)) for accurate signature.

get_n_splits (self, X=None, y=None, groups=None) 
Returns the number of splitting iterations in the cross-validator
X  [object] Always ignored, exists for compatibility.
y  [object] Always ignored, exists for compatibility.
groups  [object] Always ignored, exists for compatibility.

Returns

n_splits  [int] Returns the number of splitting iterations in the cross-validator.

split (self, X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X  [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y  [array-like, shape (n_samples,)] The target variable for supervised learning problems.
groups  [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train  [ndarray] The training set indices for that split.
test  [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.StratifiedKFold

- Visualizing cross-validation behavior in scikit-learn
- Plotting Learning Curves
- Scaling the regularization parameter for SVCs

sklearn.model_selection.StratifiedKFold

class sklearn.model_selection.StratifiedKFold(n_splits=5, shuffle=False, random_state=None)

Stratified K-Folds cross-validator
Provides train/test indices to split data in train/test sets.
This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.
Read more in the User Guide.

Parameters

n_splits  [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: n_splits default value changed from 3 to 5.

shuffle  [boolean, optional] Whether to shuffle each class’s samples before splitting into batches.
random_state [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Only used when shuffle is True. This should be left to None if shuffle is False.

See also:

RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

Notes

The implementation is designed to:

• Generate test sets such that all contain the same distribution of classes, or as close as possible.
• Be invariant to class label: relabelling y = ["Happy", "Sad"] to y = [1, 0] should not change the indices generated.
• Preserve order dependencies in the dataset ordering, when shuffle=False: all samples from class k in some test set were contiguous in y, or separated in y by samples from classes other than k.
• Generate test sets where the smallest and largest differ by at most one sample.

Changed in version 0.22: The previous implementation did not follow the last constraint.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

__init__(self, n_splits=5, shuffle=False, random_state=None) Initialize self. See help(type(self)) for accurate signature.
```

get_n_splits (self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split (self, X, y, groups=None)**

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

  Note that providing y is sufficient to generate the splits and hence np.zeros(n_samples) may be used as a placeholder for X instead of actual training data.

- **y** [array-like, shape (n_samples,)] The target variable for supervised learning problems. Stratification is done based on the y labels.

- **groups** [object] Always ignored, exists for compatibility.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

**Examples using sklearn.model_selection.StratifiedKFold**

- Recursive feature elimination with cross-validation
- Test with permutations the significance of a classification score
- GMM covariances
- Receiver Operating Characteristic (ROC) with cross validation
- Visualizing cross-validation behavior in scikit-learn

**sklearn.model_selection.StratifiedShuffleSplit**

**class sklearn.model_selection.StratifiedShuffleSplit (n_splits=10, test_size=None, train_size=None, random_state=None)**

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.
This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

**Parameters**

- **n_splits** [int, default 10] Number of re-shuffling & splitting iterations.
- **test_size** [float, int, None, optional (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.1.
- **train_size** [float, int, or None, default is None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

**Examples**

```python
given code snippet
```

</table>
__init__ (self, n_splits=10, test_size=None, train_size=None, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

get_n_splits (self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters
X [object] Always ignored, exists for compatibility.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns
n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (self, X, y, groups=None)
Generate indices to split data into training and test set.

Parameters
X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

Note that providing y is sufficient to generate the splits and hence np.zeros(n_samples) may be used as a placeholder for X instead of actual training data.
y [array-like, shape (n_samples,) or (n_samples, n_labels)] The target variable for supervised learning problems. Stratification is done based on the y labels.
groups [object] Always ignored, exists for compatibility.

Yields
train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Notes
Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.StratifiedShuffleSplit

- Visualizing cross-validation behavior in scikit-learn
- RBF SVM parameters

sklearn.model_selection.TimeSeriesSplit

class sklearn.model_selection.TimeSeriesSplit (n_splits=5, max_train_size=None)
Time Series cross-validator

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of KFold. In the kth split, it returns first k folds as train set and the (k+1)th fold as test set.
Note that unlike standard cross-validation methods, successive training sets are supersets of those that come before them.

Read more in the User Guide.

**Parameters**

- **n_splits** [int, default=5] Number of splits. Must be at least 2.

  Changed in version 0.22: n_splits default value changed from 3 to 5.

- **max_train_size** [int, optional] Maximum size for a single training set.

**Notes**

The training set has size \( i \times n_{samples} \div (n_{splits} + 1) + n_{samples} \% (n_{splits} + 1) \) in the \( i \) \(th \) split, with a test set of size \( \lceil n_{samples} \div (n_{splits} + 1) \rceil \), where \( n_{samples} \) is the number of samples.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import TimeSeriesSplit

>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> tscv = TimeSeriesSplit()
>>> print(tscv)
TimeSeriesSplit(max_train_size=None, n_splits=5)

>>> for train_index, test_index in tscv.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
TRAIN: [0 1] TEST: [2]
TRAIN: [0 1 2] TEST: [3]
TRAIN: [0 1 2 3] TEST: [4]
TRAIN: [0 1 2 3 4] TEST: [5]
```

**Methods**

- **get_n_splits** (self, X=None, y=None, groups=None) Returns the number of splitting iterations in the cross-validator

- **split** (self, X, y, groups) Generate indices to split data into training and test set.

.. _sklearn.model_selection.Splitter:

```
__init__ (self, n_splits=5, max_train_size=None)
Initialize self. See help(type(self)) for accurate signature.

get_n_splits (self, X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters

- **X** [object] Always ignored, exists for compatibility.

- **y** [object] Always ignored, exists for compatibility.
```
groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (self, X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples,)] Always ignored, exists for compatibility.
groups [array-like, with shape (n_samples,)] Always ignored, exists for compatibility.

Yields

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Examples using sklearn.model_selection.TimeSeriesSplit

7.26.2 Splitter Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_selection.check_cv((cv, y, classifier))</td>
<td>Input checker utility for building a cross-validator</td>
</tr>
<tr>
<td>model_selection.train_test_split(*arrays, ...)</td>
<td>Split arrays or matrices into random train and test subsets</td>
</tr>
</tbody>
</table>

sklearn.model_selection.check_cv

sklearn.model_selection.check_cv (cv=5, y=None, classifier=False)
Input checker utility for building a cross-validator

Parameters

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if classifier is True and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value changed from 3-fold to 5-fold.

y [array-like, optional] The target variable for supervised learning problems.
classifier [boolean, optional, default False] Whether the task is a classification task, in which case stratified KFold will be used.

Returns

checked_cv [a cross-validator instance.] The return value is a cross-validator which generates the train/test splits via the split method.

sklearn.model_selection.train_test_split

sklearn.model_selection.train_test_split(*arrays, **options)

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and next(ShuffleSplit().split(X, y)) and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the User Guide.

Parameters

*arrays [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

test_size [float, int or None, optional (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If train_size is also None, it will be set to 0.25.

train_size [float, int, or None, (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

shuffle [boolean, optional (default=True)] Whether or not to shuffle the data before splitting. If shuffle=False then stratify must be None.

stratify [array-like or None (default=None)] If not None, data is split in a stratified fashion, using this as the class labels.

Returns

splitting [list, length=2 * len(arrays)] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a scipy.sparse.csr_matrix. Else, output type is the same as the input type.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
```

7.26.3 Hyper-parameter optimizers

.. _GridSearchCV:

model_selection.GridSearchCV(estimator,...)

Exhaustive search over specified parameter values for an estimator.

model_selection.ParameterGrid(param_grid)

Grid of parameters with a discrete number of values for each.

model_selection.ParameterSampler(...[,...])

Generator on parameters sampled from given distributions.

model_selection.RandomizedSearchCV(...[,...])

Randomized search on hyper parameters.

sklearn.model_selection.GridSearchCV

class sklearn.model_selection.GridSearchCV(estimator, param_grid, scoring=None,
n_jobs=None, iid='deprecated', refit=True, cv=None, verbose=0,
pre_dispatch='2*n_jobs', error_score=nan,
return_train_score=False)

Exhaustive search over specified parameter values for an estimator.

Important members are fit, predict.

GridSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict_proba”, “dec-
sion_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the User Guide.

Parameters

estimator [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

param_grid [dict or list of dictionaries] Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

scoring [string, callable, list/tuple, dict or None, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s score method is used.

n_jobs [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
• An int, giving the exact number of total jobs that are spawned
• A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

iid [boolean, default=False] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

Deprecated since version 0.22: Parameter iid is deprecated in 0.22 and will be removed in 0.24

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross validation,
• integer, to specify the number of folds in a (Stratified)KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and \( y \) is either binary or multiclass, \texttt{StratifiedKFold} is used. In all other cases, \texttt{KFold} is used.

Refer \textit{User Guide} for the various cross-validation strategies that can be used here.

Changed in version 0.22: \texttt{cv} default value if None changed from 3-fold to 5-fold.

\textbf{refit} [boolean, string, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, \texttt{refit} can be set to a function which returns the selected \texttt{best_index_} given \texttt{cv_results_}. In that case, the \texttt{best_estimator_} and \texttt{best_parameters_} will be set according to the returned \texttt{best_index_} while the \texttt{best_score_} attribute will not be available.

The refitted estimator is made available at the \texttt{best_estimator_} attribute and permits using \texttt{predict} directly on this \texttt{GridSearchCV} instance.

Also for multiple metric evaluation, the attributes \texttt{best_index_}, \texttt{best_score_} and \texttt{best_params_} will only be available if \texttt{refit} is set and all of them will be determined w.r.t this specific scorer.

See \texttt{scoring} parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

\textbf{verbose} [integer] Controls the verbosity: the higher, the more messages.

\textbf{error_score} ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, \texttt{FitFailedWarning} is raised. This parameter does not affect the refit step, which will always raise the error. Default is \texttt{np.nan}.

\textbf{return_train_score} [boolean, default=False] If False, the \texttt{cv_results_} attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

\textbf{Attributes}

\textbf{cv_results_} [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas \texttt{DataFrame}.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>param_degree</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_t...</th>
</tr>
</thead>
<tbody>
<tr>
<td>'poly'</td>
<td></td>
<td>2</td>
<td>0.80</td>
<td>...</td>
<td>2</td>
</tr>
<tr>
<td>'poly'</td>
<td></td>
<td>3</td>
<td>0.70</td>
<td>...</td>
<td>4</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td></td>
<td>0.80</td>
<td>...</td>
<td>3</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>-</td>
<td>0.93</td>
<td>...</td>
<td>1</td>
</tr>
</tbody>
</table>

will be represented by a \texttt{cv_results_} dict of:
NOTE

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The mean_fit_time, std_fit_time, mean_score_time and std_score_time are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the cv_results_dict at the keys ending with that scorer's name ('<scorer_name>') instead of '_score' shown above. ('split0_test_precision', 'mean_train_precision' etc.)

best_estimator_ [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

See refit parameter for more information on allowed values.

best_score_ [float] Mean cross-validated score of the best_estimator

For multi-metric evaluation, this is present only if refit is specified.

This attribute is not available if refit is a function.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is present only if refit is specified.

best_index_ [int] The index (of the cv_results_arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is present only if refit is specified.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.
For multi-metric evaluation, this attribute holds the validated `scoring` dict which maps the scorer key to the scorer callable.

`n_splits_`  [int] The number of cross-validation splits (folds/iterations).

`refit_time_`  [float] Seconds used for refitting the best model on the whole dataset.

This is present only if `refit` is not False.

See also:

`ParameterGrid`  generates all the combinations of a hyperparameter grid.

`sklearn.model_selection.train_test_split`  utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.

`sklearn.metrics.make_scorer`  Make a scorer from a performance metric or loss function.

Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If `n_jobs` was set to a value higher than one, the data is copied for each point in the grid (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

Examples

```python
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV

iris = datasets.load_iris()
parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
svc = svm.SVC()
clf = GridSearchCV(svc, parameters)
clf.fit(iris.data, iris.target)
```

```python
sorted(clf.cv_results_.keys())
['mean_fit_time', 'mean_score_time', 'mean_test_score', ...
 'param_C', 'param_kernel', 'params',...
 'rank_test_score', 'split0_test_score',...
 'split2_test_score', ...
 'std_fit_time', 'std_score_time', 'std_test_score']
```

**init**(self, estimator, param_grid, scoring=None, n_jobs=None, iid='deprecated', refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score=nan, return_train_score=False)

Initialize self. See help(type(self)) for accurate signature.

**decision_function**(self, X)

Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit**(self, X, y=None, groups=None, **fit_params)

Run fit with all sets of parameters.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples, n_output) or (n_samples,), optional] Target relative to X for classification or regression; None for unsupervised learning.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_params** [dict of string -> object] Parameters passed to the fit method of the estimator

**get_params**(self, deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform**(self, Xt)

Call inverse_transform on the estimator with the best found params.
Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

**Parameters**

- **Xt** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict** *(self, X)*

Call predict on the estimator with the best found parameters. Only available if `refit=True` and the underlying estimator supports `predict`.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba** *(self, X)*

Call predict_log_proba on the estimator with the best found parameters. Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_proba** *(self, X)*

Call predict_proba on the estimator with the best found parameters. Only available if `refit=True` and the underlying estimator supports `predict_proba`.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score** *(self, X, y=None)*

Returns the score on the given data, if the estimator has been refit. This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples, n_output) or (n_samples,), optional] Target relative to X for classification or regression; None for unsupervised learning.

**Returns**

- **score** [float]

**set_params** *(self, **params)*

Set the parameters of this estimator. The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params [dict] Estimator parameters.

**Returns**
**transform** *(self, X)*

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

### Examples using **sklearn.model_selection.GridSearchCV**

- Sample pipeline for text feature extraction and evaluation

### **sklearn.model_selection.ParameterGrid**

**class sklearn.model_selection.ParameterGrid** *(param_grid)*

Grid of parameters with a discrete number of values for each.

Can be used to iterate over parameter value combinations with the Python built-in function *iter*.

Read more in the *User Guide*.

**Parameters**

- **param_grid** [dict of string to sequence, or sequence of such] The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

An empty dict signifies default parameters.

A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

See also:

**GridSearchCV** Uses ParameterGrid to perform a full parallelized parameter search.

### Examples

```python
>>> from sklearn.model_selection import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == (...
... [{'a': 1, 'b': True}, {'a': 1, 'b': False},
... {'a': 2, 'b': True}, {'a': 2, 'b': False}])
True
>>> grid = [{'kernel': ['linear']},
... {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{
... 'kernel': 'linear'},
... {'kernel': 'rbf', 'gamma': 1},
... {'kernel': 'rbf', 'gamma': 10}]
True
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
```

**__init__**(self, param_grid)

Initialize self. See help(type(self)) for accurate signature.
sklearn.model_selection.ParameterSampler

class sklearn.model_selection.ParameterSampler(param_distributions, n_iter, random_state=None)

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper-parameter search. If all parameters
are presented as a list, sampling without replacement is performed. If at least one parameter is given as a
distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for
continuous parameters.

Read more in the User Guide.

Parameters

param_distributions [dict] Dictionary with parameters names (string) as keys and distributions
or lists of parameters to try. Distributions must provide a rvs method for sampling (such
as those from scipy.stats.distributions). If a list is given, it is sampled uniformly. If a list of
dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that
dict as above.

n_iter [integer] Number of parameter settings that are produced.

random_state [int, RandomState instance or None, optional (default=None)] Pseudo random
number generator state used for random uniform sampling from lists of possible values
instead of scipy.stats distributions. If int, random_state is the seed used by the random
number generator; If RandomState instance, random_state is the random number generator;
If None, the random number generator is the RandomState instance used by np.random.

Returns

params [dict of string to any] Yields dictionaries mapping each estimator parameter to as sam-
ples value.

Examples

```python
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4,
... random_state=rng))
>>> rounded_list = [dict((k, round(v, 6))
... for (k, v) in d.items())
... for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1},
... {'b': 1.038159, 'a': 2},
... {'b': 1.878964, 'a': 2},
... {'b': 1.038159, 'a': 2}]
True
```

__init__(self, param_distributions, n_iter, random_state=None)

Initialize self. See help(type(self)) for accurate signature.
Randomized search on hyper parameters.

RandomizedSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by n_iter.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the User Guide.

New in version 0.14.

Parameters

- **estimator** [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

- **param_distributions** [dict or list of dicts] Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a rvs method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

- **n_iter** [int, default=10] Number of parameter settings that are sampled. n_iter trades off runtime vs quality of the solution.

- **scoring** [string, callable, list/tuple, dict or None, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

  For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

  NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

  See Specifying multiple metrics for evaluation for an example.

  If None, the estimator’s score method is used.

- **n_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

iid [boolean, default=False] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

Deprecated since version 0.22: Parameter iid is deprecated in 0.22 and will be removed in 0.24

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

refit [boolean, string, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, refit can be set to a function which returns the selected best_index_ given the cv_results. In that case, the best_estimator_ and best_parameters_ will be set according to the returned best_index_ while the best_score_ attribute will not be available.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this RandomizedSearchCV instance.

Also for multiple metric evaluation, the attributes best_index_, best_score_ and best_params_ will only be available if refit is set and all of them will be determined w.r.t this specific scorer.

See scoring parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

verbose [integer] Controls the verbosity: the higher, the more messages.

random_state [int, RandomState instance or None, optional, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values
instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by \texttt{np.random}.

\textbf{error_score} ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is \texttt{np.nan}.

\textbf{return_train_score} [boolean, default=False] If False, the \texttt{cv_results_} attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

\textbf{Attributes}

\textbf{cv_results_} [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_test_score</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td>0.80</td>
<td>...</td>
<td>2</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>0.90</td>
<td>...</td>
<td>1</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.3</td>
<td>0.70</td>
<td>...</td>
<td>1</td>
</tr>
</tbody>
</table>

will be represented by a \texttt{cv_results_} dict of:

```python
{
    'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'], mask = False),
    'param_gamma' : masked_array(data = [0.1 0.2 0.3], mask = False),
    'split0_test_score' : [0.80, 0.90, 0.70],
    'split1_test_score' : [0.82, 0.50, 0.70],
    'mean_test_score' : [0.81, 0.70, 0.70],
    'std_test_score' : [0.01, 0.20, 0.00],
    'rank_test_score' : [3, 1, 1],
    'split0_train_score' : [0.80, 0.92, 0.70],
    'split1_train_score' : [0.82, 0.55, 0.70],
    'mean_train_score' : [0.81, 0.74, 0.70],
    'std_train_score' : [0.01, 0.19, 0.00],
    'mean_fit_time' : [0.73, 0.63, 0.43],
    'std_fit_time' : [0.01, 0.02, 0.01],
    'mean_score_time' : [0.01, 0.06, 0.04],
    'std_score_time' : [0.00, 0.00, 0.00],
    'params' : [{'kernel' : 'rbf', 'gamma' : 0.1}, ...],
}
```

\textbf{NOTE}

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The \texttt{mean_fit_time}, \texttt{std_fit_time}, \texttt{mean_score_time} and \texttt{std_score_time} are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the \texttt{cv_results_} dict at the keys ending with that scorer's name ('_<scorer_name>')
instead of '_score' shown above. ('split0_test_precision', 'mean_train_precision' etc.)

best_estimators_ [estimator] Estimator that was chosen by the search, i.e. estimator which
gave highest score (or smallest loss if specified) on the left out data. Not available if
refit=False.

For multi-metric evaluation, this attribute is present only if refit is specified.

See refit parameter for more information on allowed values.

best_score_ [float] Mean cross-validated score of the best_estimator.

For multi-metric evaluation, this is not available if refit is False. See refit parameter
for more information.

This attribute is not available if refit is a function.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is not available if refit is False. See refit parameter
for more information.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best can-
didate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives
the parameter setting for the best model, that gives the highest mean score (search.
best_score_).

For multi-metric evaluation, this is not available if refit is False. See refit parameter
for more information.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best param-
eters for the model.

For multi-metric evaluation, this attribute holds the validated scoring dict which maps
the scorer key to the scorer callable.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

refit_time_ [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.

See also:

GridSearchCV Does exhaustive search over a grid of parameters.

ParameterSampler A generator over parameter settings, constructed from param_distributions.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring param-
eter.

If n_jobs was set to a value higher than one, the data is copied for each parameter setting(and not n_jobs
times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the
dataset is large and not enough memory is available. A workaround in this case is to set pre_dispatch.
Then, the memory is copied only pre_dispatch many times. A reasonable value for pre_dispatch is 2
* n_jobs.
### Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.model_selection import RandomizedSearchCV
>>> from scipy.stats import uniform

>>> iris = load_iris()
>>> logistic = LogisticRegression(solver='saga', tol=1e-2, max_iter=200,
... random_state=0)
>>> distributions = dict(C=uniform(loc=0, scale=4),
... penalty=['l2', 'l1'])
>>> clf = RandomizedSearchCV(logistic, distributions, random_state=0)
>>> search = clf.fit(iris.data, iris.target)
>>> search.best_params_
{'C': 2..., 'penalty': 'l1'}
```

#### __init__

```python
Initialize self. See help(type(self)) for accurate signature.
```

**decision_function** *(self, X)*

Call `decision_function` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

**Parameters**

- **X**  
  [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit** *(self, X, y=None, groups=None, **fit_params)*

Run fit with all sets of parameters.

**Parameters**
X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples, n_output) or (n_samples,), optional] Target relative to X for classification or regression; None for unsupervised learning.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_params** [dict of string -> object] Parameters passed to the fit method of the estimator

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, Xt)
Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.

Parameters

Xt [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict (self, X)
Call predict on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_log_proba (self, X)
Call predict_log_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_log_proba.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_proba (self, X)
Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
score (self, X, y=None)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.

Parameters

X [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples, n_output) or (n_samples,), optional] Target relative to X for classification or regression; None for unsupervised learning.

Returns
	score [float]

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.RandomizedSearchCV

- Comparing randomized search and grid search for hyperparameter estimation

```python
model_selection.fit_grid_point(X, y,...).
```

sklearn.model_selection.fit_grid_point

Run fit on one set of parameters.

Parameters

X [array-like, sparse matrix or list] Input data.

y [array-like or None] Targets for input data.
estimator [estimator object] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

parameters [dict] Parameters to be set on estimator for this grid point.

train [ndarray, dtype int or bool] Boolean mask or indices for training set.

test [ndarray, dtype int or bool] Boolean mask or indices for test set.

scorer [callable or None] The scorer callable object / function must have its signature as scorer(estimator, X, y).

If None the estimator’s score method is used.

verbose [int] Verbosity level.

**fit_params [kwargs] Additional parameter passed to the fit function of the estimator.

error_score ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is np.nan.

Returns

score [float] Score of this parameter setting on given test split.

parameters [dict] The parameters that have been evaluated.

n_samples_test [int] Number of test samples in this split.

sklearn.model_selection.cross_validate

sklearn.model_selection.cros

Evaluate metric(s) by cross-validation and also record fit/score times.

Read more in the User Guide.
estimator [estimator object implementing ‘fit’] The object to use to fit the data.

X [array-like] The data to fit. Can be for example a list, or an array.

y [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

scoring [string, callable, list/tuple, dict or None, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s score method is used.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross validation,
• integer, to specify the number of folds in a (Stratified)KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

n_jobs [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [integer, optional] The verbosity level.

fit_params [dict, optional] Parameters to pass to the fit method of the estimator.

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
• An int, giving the exact number of total jobs that are spawned
• A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’
**return_train_score** [boolean, default=False] Whether to include train scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

**return_estimator** [boolean, default False] Whether to return the estimators fitted on each split.

**error_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

**Returns**

- **scores** [dict of float arrays of shape (n_splits,)] Array of scores of the estimator for each run of the cross validation.

  A dict of arrays containing the score/time arrays for each scorer is returned. The possible keys for this dict are:

  - **test_score** The score array for test scores on each cv split. Suffix _score in test_score changes to a specific metric like test_r2 or test_auc if there are multiple scoring metrics in the scoring parameter.

  - **train_score** The score array for train scores on each cv split. Suffix _score in train_score changes to a specific metric like train_r2 or train_auc if there are multiple scoring metrics in the scoring parameter. This is available only if return_train_score parameter is True.

  - **fit_time** The time for fitting the estimator on the train set for each cv split.

  - **score_time** The time for scoring the estimator on the test set for each cv split. (Note time for scoring on the train set is not included even if return_train_score is set to True)

  - **estimator** The estimator objects for each cv split. This is available only if return_estimator parameter is set to True.

**See also:**

- `sklearn.model_selection.cross_val_score` Run cross-validation for single metric evaluation.
- `sklearn.model_selection.cross_val_predict` Get predictions from each split of cross-validation for diagnostic purposes.
- `sklearn.metrics.make_scorer` Make a scorer from a performance metric or loss function.

**Examples**

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_validate
>>> from sklearn.metrics import make_scorer
>>> from sklearn.metrics import confusion_matrix
>>> from sklearn.svm import LinearSVC
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
```

Single metric evaluation using `cross_validate`
Multiple metric evaluation using `cross_validate` (please refer the `scoring` parameter doc for more information)

```python
>>> scores = cross_validate(lasso, X, y, cv=3,
... scoring=('r2', 'neg_mean_squared_error'),
... return_train_score=True)
>>> print(scores['test_neg_mean_squared_error'])
[-3635.5... -3573.3... -6114.7...]
>>> print(scores['train_r2'])
[0.28010158 0.39088426 0.22784852]
```

Examples using `sklearn.model_selection.cross_validate`

- Combine predictors using stacking

`sklearn.model_selection.cross_val_predict`

`sklearn.model_selection.cross_val_predict` *(estimator, X, y=None, groups=None, cv=None, n_jobs=None, verbose=0, fit_params=None, pre_dispatch='2*n_jobs', method='predict')*

Generate cross-validated estimates for each input data point

The data is split according to the cv parameter. Each sample belongs to exactly one test set, and its prediction is computed with an estimator fitted on the corresponding training set.

Passing these predictions into an evaluation metric may not be a valid way to measure generalization performance. Results can differ from `cross_validate` and `cross_val_score` unless all tests sets have equal size and the metric decomposes over samples.

Read more in the User Guide.

**Parameters**

- `estimator` [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.
- `X` [array-like] The data to fit. Can be, for example a list, or an array at least 2d.
- `y` [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.
- `groups` [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).
- `cv` [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - `CV splitter`,
• An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, \texttt{StratifiedKFold} is used. In all other cases, \texttt{KFold} is used.

Refer \textit{User Guide} for the various cross-validation strategies that can be used here.

Changed in version 0.22: \texttt{cv} default value if None changed from 3-fold to 5-fold.

\begin{description}
\item[\texttt{n\_jobs}] [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a \texttt{joblib.parallel\_backend} context. -1 means using all processors. See \textit{Glossary} for more details.
\item[\texttt{verbose}] [integer, optional] The verbosity level.
\item[\texttt{fit\_params}] [dict, optional] Parameters to pass to the fit method of the estimator.
\item[\texttt{pre\_dispatch}] [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
\begin{itemize}
\item None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
\item An int, giving the exact number of total jobs that are spawned
\item A string, giving an expression as a function of \texttt{n\_jobs}, as in ’2*n\_jobs’
\end{itemize}
\item[\texttt{method}] [string, optional, default: ’predict’] Invokes the passed method name of the passed estimator. For method=’predict\_proba’, the columns correspond to the classes in sorted order.
\end{description}

Returns

\begin{description}
\item[\texttt{predictions}] [ndarray] This is the result of calling \texttt{method}
\end{description}

See also:

\texttt{cross\_val\_score} calculate score for each CV split

\texttt{cross\_validate} calculate one or more scores and timings for each CV split

Notes

In the case that one or more classes are absent in a training portion, a default score needs to be assigned to all instances for that class if \texttt{method} produces columns per class, as in \{'decision\_function’, ‘predict\_proba’, ‘predict\_log\_proba’\}. For \texttt{predict\_proba} this value is 0. In order to ensure finite output, we approximate negative infinity by the minimum finite float value for the dtype in other cases.

Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y, cv=3)
```
Examples using `sklearn.model_selection.cross_val_predict`

- Combine predictors using stacking
- Plotting Cross-Validated Predictions

`sklearn.model_selection.cross_val_predict`

```python
sklearn.model_selection.cross_val_predict(estimator, X, y=None, groups=None, cv=None, n_jobs=None, verbose=0, fit_params=None)
```

Evaluate a score by cross-validation

Read more in the User Guide.

Parameters

- `estimator` [estimator object implementing ‘fit’] The object to use to fit the data.
- `X` [array-like] The data to fit. Can be for example a list, or an array.
- `y` [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.
- `groups` [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., `GroupKFold`).
- `scoring` [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)` which should return only a single value.

Similar to `cross_validate` but only a single metric is permitted.

If None, the estimator’s default scorer (if available) is used.

- `cv` [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer User Guide for the various cross-validation strategies that can be used here.

 Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- `n_jobs` [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

- `verbose` [integer, optional] The verbosity level.
- `fit_params` [dict, optional] Parameters to pass to the fit method of the estimator.
**pre_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**error_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

**Returns**

scores [array of float, shape=(len(list(cv)),)] Array of scores of the estimator for each run of the cross validation.

See also:

- `sklearn.model_selection.cross_validate` To run cross-validation on multiple metrics and also to return train scores, fit times and score times.
- `sklearn.model_selection.cross_val_predict` Get predictions from each split of cross-validation for diagnostic purposes.
- `sklearn.metrics.make_scorer` Make a scorer from a performance metric or loss function.

**Examples**

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y, cv=3))
[0.33150734 0.08022311 0.03531764]
```

**Examples using sklearn.model_selection.cross_val_score**

- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
- Underfitting vs. Overfitting
- Receiver Operating Characteristic (ROC) with cross validation
- Nested versus non-nested cross-validation
- SVM-Anova: SVM with univariate feature selection
- Cross-validation on Digits Dataset Exercise
Learning curve.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the User Guide.

Parameters

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like, shape (n_samples) or (n_samples, n_features), optional] Target relative to X for classification or regression; None for unsupervised learning.

- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

- **train_sizes** [array-like, shape (n_ticks,), dttype float or int] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: np.linspace(0.1, 1.0, 5))

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).
explore_incremental_learning  [boolean, optional, default: False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

n_jobs  [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

pre_dispatch  [integer or string, optional] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like ‘2*n_jobs’.

verbose  [integer, optional] Controls the verbosity: the higher, the more messages.

shuffle  [boolean, optional] Whether to shuffle training data before taking prefixes of it based on ‘train_sizes’.

random_state  [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when shuffle is True.

error_score  ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

return_times  [boolean, optional (default: False)] Whether to return the fit and score times.

Returns

train_sizes_abs  [array, shape (n_unique_ticks,), dtype int] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.

train_scores  [array, shape (n_ticks, n_cv_folds)] Scores on training sets.

test_scores  [array, shape (n_ticks, n_cv_folds)] Scores on test set.

fit_times  [array, shape (n_ticks, n_cv_folds)] Times spent for fitting in seconds. Only present if return_times is True.

score_times  [array, shape (n_ticks, n_cv_folds)] Times spent for scoring in seconds. Only present if return_times is True.

Notes

See examples/model_selection/plot_learning_curve.py

Examples using sklearn.model_selection.learning_curve

• Comparison of kernel ridge regression and SVR
• Plotting Learning Curves
**sklearn.model_selection.permutation_test_score**

`sklearn.model_selection.permutation_test_score(estimator, X, y, groups=None, cv=None, n_permutations=100, n_jobs=None, random_state=0, verbose=0, scoring=None)`

Evaluate the significance of a cross-validated score with permutations

Read more in the **User Guide**.

**Parameters**

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
- **X** [array-like of shape at least 2D] The data to fit.
- **y** [array-like] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like, with shape (n_samples,), optional] Labels to constrain permutation within groups, i.e. y values are permuted among samples with the same group identifier. When not specified, y values are permuted among all samples.
  
  When a grouped cross-validator is used, the group labels are also passed on to the split method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.

- **scoring** [string, callable or None, optional, default: None] A single string (see **The scoring parameter: defining model evaluation rules**) or a callable (see **Defining your scoring strategy from metric functions**) to evaluate the predictions on the test set.

  If None the estimator’s score method is used.

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  
  - None, to use the default 5-fold cross validation,
  
  - integer, to specify the number of folds in a (Stratified)KFold,
  
  - **CV splitter**,
  
  - An iterable yielding (train, test) splits as arrays of indices.

  For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

  Refer **User Guide** for the various cross-validation strategies that can be used here.

  Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **n_permutations** [integer, optional] Number of times to permute y.

- **n_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See **Glossary** for more details.

- **random_state** [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

- **verbose** [integer, optional] The verbosity level.

**Returns**

- **score** [float] The true score without permuting targets.
**permutation_scores** [array, shape (n_permutations,)] The scores obtained for each permutations.

**pvalue** [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

\[(C + 1) / (n\_permutations + 1)\]

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.

**Notes**

This function implements Test 1 in:

**Examples using sklearn.model_selection.permutation_test_score**

- Test with permutations the significance of a classification score

**sklearn.model_selection.validation_curve**

```
sklearn.model_selection.validation_curve(estimator, X, y, param_name, param_range, groups=None, cv=None, scoring=None, n_jobs=None, pre_dispatch='all', verbose=0, error_score=nan)
```

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the User Guide.

**Parameters**

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like, shape (n_samples) or (n_samples, n_features), optional] Target relative to X for classification or regression; None for unsupervised learning.

- **param_name** [string] Name of the parameter that will be varied.

- **param_range** [array-like, shape (n_values,)] The values of the parameter that will be evaluated.

- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

scoring [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

n_jobs [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

pre_dispatch [integer or string, optional] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like ‘2*n_jobs’.

verbose [integer, optional] Controls the verbosity: the higher, the more messages.

error_score ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Returns

train_scores [array, shape (n_ticks, n_cv_folds)] Scores on training sets.

test_scores [array, shape (n_ticks, n_cv_folds)] Scores on test set.

7.27 sklearn.multiclass: Multiclass and multilabel classification

7.27.1 Multiclass and multilabel classification strategies

This module implements multiclass learning algorithms:

- one-vs-the-rest / one-vs-all
- one-vs-one
- error correcting output codes
The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.

All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a `predict_proba` method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample will not sum to unity, as they do in the single label case.

**User guide:** See the *Multiclass and multilabel algorithms* section for further details.

```python
multiclass.OneVsRestClassifier(estimator[, One-vs-the-rest (OvR) multiclass/multilabel strategy
...])
multiclass.OneVsOneClassifier(estimator[, One-vs-one multiclass strategy
...])
multiclass.OutputCodeClassifier(estimator[, (Error-Correcting) Output-Code multiclass strategy
...])
```

### 7.27.2 sklearn.multiclass.OneVsRestClassifier

**class** `sklearn.multiclass.OneVsRestClassifier` *(estimator, n_jobs=None)*

One-vs-the-rest (OvR) multiclass/multilabel strategy

Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is fitted against all the other classes. In addition to its computational efficiency (only `n_classes` classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.

This strategy can also be used for multilabel learning, where a classifier is used to predict multiple labels for instance, by fitting on a 2-d matrix in which cell `[i, j]` is 1 if sample `i` has label `j` and 0 otherwise.

In the multilabel learning literature, OvR is also known as the binary relevance method.

Read more in the **User Guide**.

**Parameters**

- `estimator` [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.

- `n_jobs` [int or None, optional (default=None)] The number of jobs to use for the computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**Attributes**

- `estimators_` [list of `n_classes` estimators] Estimators used for predictions.

- `classes_` [array, shape = `[n_classes]`] Class labels.

- `n_classes_` [int] Number of classes.

- `label_binarizer_` [LabelBinarizer object] Object used to transform multiclass labels to binary labels and vice-versa.
multilabel_ [boolean] Whether this is a multilabel classifier

Examples

```python
>>> import numpy as np
>>> from sklearn.multiclass import OneVsRestClassifier
>>> from sklearn.svm import SVC

>>> X = np.array([[10, 10],
...               [8, 10],
...               [-5, 5.5],
...               [-5.4, 5.5],
...               [-20, -20],
...               [-15, -20]])
>>> y = np.array([0, 0, 1, 1, 2, 2])
>>> clf = OneVsRestClassifier(SVC()).fit(X, y)
>>> clf.predict([[-19, -20], [9, 9], [-5, 5]])
array([2, 0, 1])
```

</tbody>
</table>

__init__ (self, estimator, n_jobs=None)
Initialize self. See help(type(self)) for accurate signature.

decision_function(self, X)
Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the decision_function method.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

T [array-like of shape (n_samples, n_classes)]

fit (self, X, y)
Fit underlying estimators.

Parameters

X [(sparse) array-like of shape (n_samples, n_features)] Data.
y \quad \text{[(sparse) array-like of shape \((n_{\text{samples}},)\) or \((n_{\text{samples}}, n_{\text{classes}})\)] Multi-class targets. An indicator matrix turns on multilabel classification.}

Returns

self

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property multilabel_
Whether this is a multilabel classifier

partial_fit (self, X, y, classes=None)
Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

Parameters

X \quad \text{[(sparse) array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)] Data.}

y \quad \text{[(sparse) array-like of shape \((n_{\text{samples}},)\) or \((n_{\text{samples}}, n_{\text{classes}})\)] Multi-class targets. An indicator matrix turns on multilabel classification.}

classes [array, shape \((n_{\text{classes}},)\)] Classes across all calls to partial_fit. Can be obtained via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns

self

predict (self, X)
Predict multi-class targets using underlying estimators.

Parameters

X \quad \text{[(sparse) array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)] Data.}

Returns

y \quad \text{[(sparse) array-like of shape \((n_{\text{samples}},)\) or \((n_{\text{samples}}, n_{\text{classes}})\)] Predicted multi-class targets.}

predict_proba (self, X)
Probability estimates.

The returned estimates for all classes are ordered by label of classes.

Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.

In the single label multiclass case, the rows of the returned matrix sum to 1.
Parameters

X [array-like of shape (n_samples, n_features)]

Returns

T [(sparse) array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

score (self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.multiclass.OneVsRestClassifier

• Multilabel classification
• Receiver Operating Characteristic (ROC)
• Precision-Recall
• Classifier Chain

7.27.3 sklearn.multiclass.OneVsOneClassifier

class sklearn.multiclass.OneVsOneClassifier (estimator, n_jobs=None)

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit n_classes * (n_classes - 1) / 2 classifiers, this method is usually slower than one-vs-the-rest, due to its O(n_classes^2) complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don’t scale well with n_samples. This is because each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used n_classes times.
Parameters

- **estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.
- **n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

Attributes

- **estimators_** [list of n_classes * (n_classes - 1) / 2 estimators] Estimators used for predictions.
- **classes_** [numpy array of shape [n_classes]] Array containing labels.
- **n_classes_** [int] Number of classes
- **pairwise_indices_** [list, length = len(estimators_), or None] Indices of samples used when training the estimators. None when estimator does not have `_pairwise` attribute.

Methods

- `decision_function(self, X)` Decision function for the OneVsOneClassifier.
- `fit(self, X, y)` Fit underlying estimators.
- `get_params(self[, deep])` Get parameters for this estimator.
- `partial_fit(self, X, y[, classes])` Partially fit underlying estimators
- `predict(self, X)` Estimate the best class label for each sample in X.
- `score(self, X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(self, **params)` Set the parameters of this estimator.

```python
__init__ (self, estimator, n_jobs=None)
Initialize self. See help(type(self)) for accurate signature.
```

```python
decision_function(self, X)
Decision function for the OneVsOneClassifier.
The decision values for the samples are computed by adding the normalized sum of pair-wise classification confidence levels in the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie.

Parameters

- **X** [array-like of shape (n_samples, n_features)]

Returns

- **Y** [array-like of shape (n_samples, n_classes)]

```python
fit(self, X, y)
Fit underlying estimators.

Parameters

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.
- **y** [array-like of shape (n_samples,)] Multi-class targets.
```
Returns
self

**get_params** (*self, deep=True*)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit** (*self, X, y, classes=None*)
Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

**Parameters**

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.
- **y** [array-like of shape (n_samples,)] Multi-class targets.
- **classes** [array, shape (n_classes,)] Classes across all calls to partial_fit. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

**Returns**
self

**predict** (*self, X*)
Estimate the best class label for each sample in X.

This is implemented as `argmax(decision_function(X), axis=1)` which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.

**Parameters**

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.

**Returns**

- **y** [numpy array of shape [n_samples]] Predicted multi-class targets.

**score** (*self, X, y, sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.
**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

### 7.27.4 sklearn.multiclass.OutputCodeClassifier

**class** sklearn.multiclass.OutputCodeClassifier *(estimator, code_size=1.5, random_state=None, n_jobs=None)*

(Error-Correcting) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model (0 < code_size < 1) or for making the model more robust to errors (code_size > 1). See the documentation for more details.

Read more in the User Guide.

Parameters

**estimator** [estimator object] An estimator object implementing fit and one of decision_function or predict_proba.

**code_size** [float] Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.

**random_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the codebook. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

**estimators** [list of int (n_classes * code_size) estimators] Estimators used for predictions.

**classes** [numpy array of shape [n_classes]] Array containing labels.

**code_book** [numpy array of shape [n_classes, code_size]] Binary array containing the code of each class.

</tr>
</tbody>
</table>

__init__ (self, estimator, code_size=1.5, random_state=None, n_jobs=None)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)

Fit underlying estimators.

Parameters

- `X` [(sparse) array-like of shape (n_samples, n_features)] Data.
- `y` [numpy array of shape [n_samples]] Multi-class targets.

Returns

- `self` |

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` [mapping of string to any] Parameter names mapped to their values.

predict (self, X)

Predict multi-class targets using underlying estimators.

Parameters

- `X` [(sparse) array-like of shape (n_samples, n_features)] Data.

Returns

- `clf.predict___ ____([[0, 0, 0, 0]])` array([1])

7.27. sklearn.multiclass: Multiclass and multilabel classification
y  [numpy array of shape [n_samples]] Predicted multi-class targets.

score (self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- X  [array-like of shape (n_samples, n_features)] Test samples.
- y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

- **params  [dict] Estimator parameters.

Returns

7.28 sklearn.multioutput: Multioutput regression and classification

This module implements multioutput regression and classification.

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. The meta-estimator extends single output estimators to multioutput estimators.

User guide: See the Multiclass and multilabel algorithms section for further details.

multioutput.ClassifierChain(base_estimator)  A multi-label model that arranges binary classifiers into a chain.

multioutput.MultiOutputRegressor(estimator, Multi target regression

multioutput.MultiOutputClassifier( estimator, Multi target classification

multioutput.RegressorChain(base_estimator[, ...])  A multi-label model that arranges regressions into a chain.

7.28.1 sklearn.multioutput.ClassifierChain

class sklearn.multioutput.ClassifierChain(base_estimator, order=None, cv=None, random_state=None)

A multi-label model that arranges binary classifiers into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to
the model plus the predictions of models that are earlier in the chain.

Read more in the User Guide.
New in version 0.19.

Parameters

**base_estimator**  [estimator] The base estimator from which the classifier chain is built.

**order**  [array-like of shape (n_outputs,) or ‘random’, optional] By default the order will be determined by the order of columns in the label matrix Y:

```python
order = [0, 1, 2, ..., Y.shape[1] - 1]
```

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5:

```python
order = [1, 3, 2, 4, 0]
```

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is ‘random’ a random ordering will be used.

**cv**  [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

**random_state**  [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

The random number generator is used to generate random chain orders.

Attributes

**classes_**  [list] A list of arrays of length len(estimators_) containing the class labels for each estimator in the chain.

**estimators_**  [list] A list of clones of base_estimator.

**order_**  [list] The order of labels in the classifier chain.

See also:

RegressorChain  Equivalent for regression

MultioutputClassifier  Classifies each output independently rather than chaining.

#### __init__(self, base_estimator, order=None, cv=None, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

#### decision_function(self, X)

Evaluate the decision_function of the models in the chain.

**Parameters**

- **X** ([array-like, shape (n_samples, n_features)])

**Returns**

- **Y_decision** ([array-like, shape (n_samples, n_classes )]) Returns the decision function of the sample for each model in the chain.

#### fit(self, X, Y)

Fit the model to data matrix X and targets Y.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)] The input data.
- **Y** ([array-like, shape (n_samples, n_classes)] The target values.

**Returns**

- **self** [object]

#### get_params(self, deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

#### predict(self, X)

Predict on the data matrix X using the ClassifierChain model.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)] The input data.

**Returns**

- **Y_pred** [array-like, shape (n_samples, n_classes)] The predicted values.
**predict_proba** *(self, X)*

Predict probability estimates.

**Parameters**

- `X` ([array-like, sparse matrix], shape (n_samples, n_features))

**Returns**

- `Y_prob` ([array-like, shape (n_samples, n_classes)])

**score** *(self, X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- `X` ([array-like of shape (n_samples, n_features)] Test samples.
- `y` ([array-like of shape (n_samples,)] or (n_samples, n_outputs)) True labels for X.
- `sample_weight` [array-like of shape (n_samples,)], default=None] Sample weights.

**Returns**

- `score` [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- `**params` [dict] Estimator parameters.

**Returns**

**Examples using sklearn.multioutput.ClassifierChain**

- **Classifier Chain**

**7.28.2 sklearn.multioutput.MultiOutputRegressor**

**class** `sklearn.multioutput.MultiOutputRegressor` *(estimator, n_jobs=None)*

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

**Parameters**

- `estimator` [estimator object] An estimator object implementing `fit` and `predict`.
- `n_jobs` [int or None, optional (default=None)] The number of jobs to run in parallel for `fit`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.
When individual estimators are fast to train or predict using `n_jobs>1` can result in slower performance due to the overhead of spawning processes.

**Attributes**

- `estimators_` [list of `n_output` estimators] Estimators used for predictions.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>

</tr>
</tbody>
</table>

**__init__**(self, estimator, n_jobs=None)  
Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y[, sample_weight])  
Fit the model to data. Fit a separate model for each output variable.

**Parameters**

- `X` [(sparse) array-like, shape (n_samples, n_features)] Data.
- `y` [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets. An indicator matrix turns on multilabel estimation.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

- `self` [object]

**get_params**(self, deep=True)  
Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names names mapped to their values.

**partial_fit**(self, X, y, sample_weight=None)  
Incrementally fit the model to data. Fit a separate model for each output variable.

**Parameters**

- `X` [(sparse) array-like, shape (n_samples, n_features)] Data.
- `y` [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns

self [object]

predict (self, X)

Predict multi-output variable using a model trained for each target variable.

Parameters

X [(sparse) array-like, shape (n_samples, n_features)] Data.

Returns

y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

score (self, X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the regression sum of squares ((y_true - y_true.mean()) ** 2).sum(). Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape (n_samples, n_features)] Test samples.
y [array-like, shape (n_samples) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like, shape [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

R^2 is calculated by weighting all the targets equally using multioutput='uniform_average'.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.
Examples using `sklearn.multioutput.MultiOutputRegressor`

- Comparing random forests and the multi-output meta estimator

### 7.28.3 `sklearn.multioutput.MultiOutputClassifier`

**class** `sklearn.multioutput.MultiOutputClassifier(estimator, n_jobs=None)`

Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that do not natively support multi-target classification.

**Parameters**

- **estimator** [estimator object] An estimator object implementing `fit`, `score` and `predict_proba`.
- **n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. It does each target variable in y in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Attributes**

- **estimators_** [list of n_output estimators] Estimators used for predictions.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.multioutput import MultiOutputClassifier
>>> from sklearn.neighbors import KNeighborsClassifier

>>> X, y = make_multilabel_classification(n_classes=3, random_state=0)
>>> clf = MultiOutputClassifier(KNeighborsClassifier()).fit(X, y)
>>> clf.predict(X[-2:]),
array([[1, 1, 0], [1, 1, 1]])
```

**Methods**

- `fit(self, X, Y[, sample_weight])` Fit the model to data matrix X and targets Y.
- `get_params(self[, deep])` Get parameters for this estimator.
- `partial_fit(self, X, y[, classes, sample_weight])` Incrementally fit the model to data.
- `predict(self, X)` Predict multi-output variable using a model
- `score(self, X, y)` Returns the mean accuracy on the given test data and labels.
- `set_params(self, **params)` Set the parameters of this estimator.

**__init__(self, estimator, n_jobs=None)**

Initialize self. See help(type(self)) for accurate signature.

**fit(self, X, Y, sample_weight=None)**

Fit the model to data matrix X and targets Y.
Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input data.
- **Y** [array-like of shape (n_samples, n_classes)] The target values.
- **sample_weight** [array-like of shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying classifier supports sample weights.

Returns

- **self** [object]

**get_params**(self, deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit**(self, X, y, classes=None, sample_weight=None)

Incrementally fit the model to data. Fit a separate model for each output variable.

Parameters

- **X** [(sparse) array-like, shape (n_samples, n_features)] Data.
- **y** [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets.
- **classes** [list of numpy arrays, shape (n_outputs)] Each array is unique classes for one output in str/int Can be obtained by via [np.unique(y[:, i]) for i in range(y.shape[1])], where y is the target matrix of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns

- **self** [object]

**predict**(self, X)

Predict multi-output variable using a model trained for each target variable.

Parameters

- **X** [(sparse) array-like, shape (n_samples, n_features)] Data.

Returns

- **y** [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**property predict_proba**

Probability estimates. Returns prediction probabilities for each class of each output.

This method will raise a ValueError if any of the estimators do not have predict_proba.
Parameters

X [array-like, shape (n_samples, n_features)] Data

Returns

p [array of shape (n_samples, n_classes), or a list of n_outputs such arrays if n_outputs > 1.] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (self, X, y)

Returns the mean accuracy on the given test data and labels.

Parameters

X [array-like, shape [n_samples, n_features]] Test samples
y [array-like, shape [n_samples, n_outputs]] True values for X

Returns

scores [float] accuracy_score of self.predict(X) versus y

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.28.4 sklearn.multioutput.RegressorChain

class sklearn.multioutput.RegressorChain(base_estimator, order=None, cv=None, random_state=None)

A multi-label model that arranges regressions into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the User Guide.

Parameters

base_estimator [estimator] The base estimator from which the classifier chain is built.

order [array-like of shape (n_outputs,) or ‘random’, optional] By default the order will be determined by the order of columns in the label matrix Y.:

order = [0, 1, 2, ..., Y.shape[1] - 1]

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5.:

order = [1, 3, 2, 4, 0]
means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is ‘random’ a random ordering will be used.

**cv**  [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

**random_state**  [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

The random number generator is used to generate random chain orders.

**Attributes**

**estimators_**  [list] A list of clones of base_estimator.

**order_**  [list] The order of labels in the classifier chain.

**See also:**

**ClassifierChain** Equivalent for classification

**MultioutputRegressor** Learns each output independently rather than chaining.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fit</strong>(self, X, Y)</td>
<td>Fit the model to data matrix X and targets Y.</td>
</tr>

<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><strong>predict</strong>(self, X)</td>
<td>Predict on the data matrix X using the Classifier-Chain model.</td>
</tr>
<tr>
<td><strong>score</strong>(self, X, y[, sample_weight])</td>
<td>Return the coefficient of determination R^2 of the prediction.</td>
</tr>
<tr>
<td><strong>set_params</strong>(self, **params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**__init__**(self, base_estimator, order=None, cv=None, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, Y)

Fit the model to data matrix X and targets Y.

**Parameters**

- **X**  [[array-like, sparse matrix], shape (n_samples, n_features)] The input data.
- **Y**  [array-like, shape (n_samples, n_classes)] The target values.

**Returns**

- **self**  [object]
**get_params** *(self, deep=True)*
Get parameters for this estimator.

Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(self, X)*
Predict on the data matrix X using the ClassifierChain model.

Parameters

**X** [[array-like, sparse matrix], shape (n_samples, n_features)] The input data.

Returns

**Y_pred** [array-like, shape (n_samples, n_classes)] The predicted values.

**score** *(self, X, y, sample_weight=None)*
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] $R^2$ of self.predict(X) wrt. $y$.

Notes

The R2 score used when calling *score* on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the *score* method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer 'r2' uses *multioutput='uniform_average'*)

**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.
7.29 sklearn.naive_bayes: Naive Bayes

The sklearn.naive_bayes module implements Naive Bayes algorithms. These are supervised learning methods based on applying Bayes’ theorem with strong (naive) feature independence assumptions.

User guide: See the Naive Bayes section for further details.

<table>

7.29.1 sklearn.naive_bayes.BernoulliNB

class sklearn.naive_bayes.BernoulliNB(alpha=1.0, binarize=0.0, fit_prior=True, class_prior=None)

Naive Bayes classifier for multivariate Bernoulli models.

Like MultinomialNB, this classifier is suitable for discrete data. The difference is that while MultinomialNB works with occurrence counts, BernoulliNB is designed for binary/boolean features.

Read more in the User Guide.

Parameters

- **alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- **binarize** [float or None, optional (default=0.0)] Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.
- **fit_prior** [bool, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- **class_prior** [array-like, size=[n_classes,], optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes

- **class_count_** [array, shape = [n_classes]] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- **class_log_prior_** [array, shape = [n_classes]] Log probability of each class (smoothed).
- **classes_** [array, shape (n_classes,)] Class labels known to the classifier
- **feature_count_** [array, shape = [n_classes, n_features]] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
feature_log_prob_ [array, shape = [n_classes, n_features]] Empirical log probability of features given a class, P(x_i|y).

n_features_ [int] Number of features of each sample.

References

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> Y = np.array([1, 2, 3, 4, 4, 5])
>>> from sklearn.naive_bayes import BernoulliNB
>>> clf = BernoulliNB()
>>> clf.fit(X, Y)
BernoulliNB()
>>> print(clf.predict(X[2:3]))
[3]
```

__init__(self, alpha=1.0, binarize=0.0, fit_prior=True, class_prior=None)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y, sample_weight=None)

Fit Naive Bayes classifier according to X, y

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns
self [object]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.
This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.
This is especially useful when the whole dataset is too big to fit in memory at once.
This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

classes [array-like of shape (n_classes) (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns
self [object]

predict (self, X)
Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns
C [ndarray of shape (n_samples,)] Predicted target values for X

predict_log_proba (self, X)
Return log-probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]
Returns

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**predict_proba**(*self*, *X*)

Return probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**score**(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(*self*, **params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

**Examples using sklearn.naive_bayes.BernoulliNB**

- Hashing feature transformation using Totally Random Trees
- Classification of text documents using sparse features

**7.29.2 sklearn.naive_bayes.CategoricalNB**

class sklearn.naive_bayes.CategoricalNB(*alpha=1.0, fit_prior=True, class_prior=None*)

Naive Bayes classifier for categorical features
The categorical Naive Bayes classifier is suitable for classification with discrete features that are categorically distributed. The categories of each feature are drawn from a categorical distribution.

Read more in the User Guide.

Parameters

**alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

**fit_prior** [boolean, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

**class_prior** [array-like, size (n_classes,), optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes

**category_count_** [list of arrays, len n_features] Holds arrays of shape (n_classes, n_categories of respective feature) for each feature. Each array provides the number of samples encountered for each class and category of the specific feature.

**class_count_** [array, shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

**class_log_prior_** [array, shape (n_classes,)] Smoothed empirical log probability for each class.

**classes_** [array, shape (n_classes,)] Class labels known to the classifier

**feature_log_prob_** [list of arrays, len n_features] Holds arrays of shape (n_classes, n_categories of respective feature) for each feature. Each array provides the empirical log probability of categories given the respective feature and class, \( P(x_i | y) \).

**n_features_** [int] Number of features of each sample.

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import CategoricalNB
>>> clf = CategoricalNB()
>>> clf.fit(X, y)
CategoricalNB()
>>> print(clf.predict(X[2:3]))
[3]
```

Methods

```
fit(self, X, y[, sample_weight])  Fit Naive Bayes classifier according to X, y
get_params(self[, deep])  Get parameters for this estimator.
partial_fit(self, X, y[, classes, sample_weight])  Incremental fit on a batch of samples.
predict(self, X)  Perform classification on an array of test vectors X.
predict_log_proba(self, X)  Return log-probability estimates for the test vector X.
```

__init__(self, alpha=1.0, fit_prior=True, class_prior=None)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y, sample_weight=None)

Fit Naive Bayes classifier according to X, y

Parameters

- **X** [(array-like, sparse matrix), shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of features. Here, each feature of X is assumed to be from a different categorical distribution. It is further assumed that all categories of each feature are represented by the numbers 0, . . . , n - 1, where n refers to the total number of categories for the given feature. This can, for instance, be achieved with the help of OrdinalEncoder.

- **y** [array-like, shape = [n_samples]] Target values.

- **sample_weight** [array-like, shape = [n_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

Returns

- **self** [object]

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y, classes=None, sample_weight=None)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

- **X** [(array-like, sparse matrix), shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of features. Here, each feature of X is assumed to be from a different categorical distribution. It is further assumed that all categories of each feature are represented by the numbers 0, . . . , n - 1, where n refers to the total number of categories for the given feature. This can, for instance, be achieved with the help of OrdinalEncoder.

- **y** [array-like, shape = [n_samples]] Target values.
classes [array-like, shape = [n_classes] (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like, shape = [n_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

Returns

self [object]

predict (self, X)

Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X

predict_log_proba (self, X)

Return log-probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

predict_proba (self, X)

Return probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score (self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.
**set_params** *(self, **params)*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

### 7.29.3 sklearn.naive_bayes.ComplementNB

**class** sklearn.naive_bayes.ComplementNB *(alpha=1.0, fit_prior=True, class_prior=None, norm=False)*)

The Complement Naive Bayes classifier described in Rennie et al. (2003).

The Complement Naive Bayes classifier was designed to correct the “severe assumptions” made by the standard Multinomial Naive Bayes classifier. It is particularly suited for imbalanced data sets.

Read more in the *User Guide*.

**Parameters**

alpha [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

fit_prior [boolean, optional (default=True)] Only used in edge case with a single class in the training set.

class_prior [array-like, size (n_classes,), optional (default=None)] Prior probabilities of the classes. Not used.

norm [boolean, optional (default=False)] Whether or not a second normalization of the weights is performed. The default behavior mirrors the implementations found in Mahout and Weka, which do not follow the full algorithm described in Table 9 of the paper.

**Attributes**

class_count_ [array, shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [array, shape (n_classes,)] Smoothed empirical log probability for each class. Only used in edge case with a single class in the training set.

classes_ [array, shape (n_classes,)] Class labels known to the classifier

feature_all_ [array, shape (n_features,)] Number of samples encountered for each feature during fitting. This value is weighted by the sample weight when provided.

feature_count_ [array, shape (n_classes, n_features)] Number of samples encountered for each class, feature during fitting. This value is weighted by the sample weight when provided.

feature_log_prob_ [array, shape (n_classes, n_features)] Empirical weights for class complements.

n_features_ [int] Number of features of each sample.

**Parameters**
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit**(self, X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

classes [array-like of shape (n_classes) (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns

self [object]

**predict**(self, X)
Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba**(self, X)
Return log-probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**predict_proba**(self, X)
Return probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]
Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.naive_bayes.ComplementNB

• Classification of text documents using sparse features

7.29.4 sklearn.naive_bayes.GaussianNB

class sklearn.naive_bayes.GaussianNB (priors=None, var_smoothing=1e-09)
Gaussian Naive Bayes (GaussianNB)
Can perform online updates to model parameters via partial_fit. For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:
Read more in the User Guide.

Parameters

priors [array-like, shape (n_classes,)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

var_smoothing [float, optional (default=1e-9)] Portion of the largest variance of all features that is added to variances for calculation stability.
Attributes

- **class_count_** [array, shape (n_classes,)] number of training samples observed in each class.
- **class_prior_** [array, shape (n_classes,)] probability of each class.
- **classes_** [array, shape (n_classes,)] class labels known to the classifier.
- **epsilon_** [float] absolute additive value to variances.
- **sigma_** [array, shape (n_classes, n_features)] variance of each feature per class.
- **theta_** [array, shape (n_classes, n_features)] mean of each feature per class.

Examples

```python
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB()
>>> print(clf.predict([[0.8, -1]]))
1
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB()
>>> print(clf_pf.predict([[0.8, -1]]))
1
```

__init__ (self, priors=None, var_smoothing=1e-09)

Initialize self. See help(type(self)) for accurate signature.

```
fit (self, X, y, sample_weight=None)
```

Fit Gaussian Naive Bayes according to X, y

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples,)] Target values.

sample_weight [array-like, shape (n_samples,), optional (default=None)] Weights applied to individual samples (1. for unweighted).

New in version 0.17: Gaussian Naive Bayes supports fitting with sample_weight.

Returns

self [object]

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit (self, X, y, classes=None, sample_weight=None)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like, shape (n_samples,)] Target values.

classes [array-like, shape (n_classes,), optional (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like, shape (n_samples,), optional (default=None)] Weights applied to individual samples (1. for unweighted).

New in version 0.17.

Returns

self [object]

predict (self, X)

Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X

predict_log_proba (self, X)

Return log-probability estimates for the test vector X.
Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

predict_proba (self, X)

Return probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score (self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.naive_bayes.GaussianNB

• Comparison of Calibration of Classifiers
• Probability Calibration curves
• Probability calibration of classifiers
• Classifier comparison
7.29.5 sklearn.naive_bayes.MultinomialNB

class sklearn.naive_bayes.MultinomialNB(alpha=1.0, fit_prior=True, class_prior=None)

Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the User Guide.

Parameters

alpha [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

fit_prior [boolean, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

class_prior [array-like, size (n_classes,), optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes

class_count_ [array, shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [array, shape (n_classes,)] Smoothed empirical log probability for each class.

classes_ [array, shape (n_classes,)] Class labels known to the classifier

goef_ [array, shape (n_classes, n_features)] Mirrors feature_log_prob_ for interpreting MultinomialNB as a linear model.

feature_count_ [array, shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

feature_log_prob_ [array, shape (n_classes, n_features)] Empirical log probability of features given a class, P (x_i | y).

intercept_ [array, shape (n_classes,)] Mirrors class_log_prior_ for interpreting MultinomialNB as a linear model.

n_features_ [int] Number of features of each sample.

Notes

For the rationale behind the names coef_ and intercept_, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.
References

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
MultinomialNB()
>>> print(clf.predict(X[2:3]))
[3]
```

</tbody>
</table>

__init__ (self, alpha=1.0, fit_prior=True, class_prior=None)

Initialize self. See help(type(self)) for accurate signature.

`fit()` (self, X, y, sample_weight=None)

Fit Naive Bayes classifier according to X, y

Parameters

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns

- **self** [object]

`get_params()` (self, deep=True)

Get parameters for this estimator.
Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit** *(self, X, y, classes=None, sample_weight=None)*
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**y** [array-like of shape (n_samples,)] Target values.

**classes** [array-like of shape (n_classes) (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

**sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns

**self** [object]

**predict** *(self, X)*
Perform classification on an array of test vectors X.

Parameters

**X** [array-like of shape (n_samples, n_features)]

Returns

**C** [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba** *(self, X)*
Return log-probability estimates for the test vector X.

Parameters

**X** [array-like of shape (n_samples, n_features)]

Returns

**C** [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**predict_proba** *(self, X)*
Return probability estimates for the test vector X.

Parameters

7.29. **sklearn.naive_bayes**: Naive Bayes
X [array-like of shape (n_samples, n_features)]

Returns
C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

Examples using sklearn.naive_bayes.MultinomialNB

- Out-of-core classification of text documents
- Classification of text documents using sparse features

7.30 sklearn.neighbors: Nearest Neighbors

The sklearn.neighbors module implements the k-nearest neighbors algorithm.

User guide: See the Nearest Neighbors section for further details.

### 7.30.1 sklearn.neighbors.BallTree

**class sklearn.neighbors.BallTree**

BallTree for fast generalized N-point problems

```python
BallTree(X, leaf_size=40, metric='minkowski', **kwargs)
```

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

- `leaf_size` [positive integer (default = 40)] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

- `metric` [string or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball_tree.valid_metrics gives a list of the metrics which are valid for BallTree.

**Additional keywords are passed to the distance metric class.**

**Note:** Callable functions in the metric parameter are NOT supported for KDTree and Ball Tree. Function call overhead will result in very poor performance.

**Attributes**

- `data` [memory view] The training data

**Examples**

Query for k-nearest neighbors

<td><code>query_radius(self, X, r, count_only = False):</code></td>
</tr>
<tr>
<td><code>two_point_correlation()</code></td>
<td>Compute the two-point correlation function</td>
</tr>
</tbody>
</table>

__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

**kernel_density (self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth_first=True, return_log=False)**
Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
- **h** [float] the bandwidth of the kernel
- **kernel** [string] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’
- **atol, rtol** [float (default = 0)] Specify the desired relative and absolute tolerance of the result. If the true result is K_true, then the returned result K_ret satisfies abs(K_true - K_ret) < atol + rtol * K_ret The default is zero (i.e. machine precision) for both.
- **breadth_first** [boolean (default = False)] if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.
- **return_log** [boolean (default = False)] return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

**Returns**

- **density** [ndarray] The array of (log)-density evaluations, shape = X.shape[:-1]

**query (X, k=1, return_distance=True, dualtree=False, breadth_first=False)**
query the tree for the k nearest neighbors

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] An array of points to query
- **k** [integer (default = 1)] The number of nearest neighbors to return
- **return_distance** [boolean (default = True)] if True, return a tuple (d, i) of distances and indices if False, return array i
**dualtree** [boolean (default = False)] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

**breadth_first** [boolean (default = False)] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

**sort_results** [boolean (default = True)] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

**Returns**

i [if return_distance == False]

(d, i) [if return_distance == True]

d [array of doubles - shape: x.shape[:-1] + (k,)] each entry gives the list of distances to the neighbors of the corresponding point

i [array of integers - shape: x.shape[:-1] + (k,)] each entry gives the list of indices of neighbors of the corresponding point

**query_radius**

query_radius(self, X, r, count_only = False):

query the tree for neighbors within a radius r

**Parameters**

X [array-like of shape (n_samples, n_features)] An array of points to query

r [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.

**return_distance** [boolean (default = False)] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be calculated explicitly for return_distance=False. Results are not sorted by default: see sort_results keyword.

**count_only** [boolean (default = False)] if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

**sort_results** [boolean (default = False)] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

**Returns**

**count** [if count_only == True]

**ind** [if count_only == False and return_distance == False]

**(ind, dist)** [if count_only == False and return_distance == True]

**count** [array of integers, shape = X.shape[:-1]] each entry gives the number of neighbors within a distance r of the corresponding point.

**ind** [array of objects, shape = X.shape[:-1]] each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.
**dist** [array of objects, shape = X.shape[:-1]] each element is a numpy double array listing the distances corresponding to indices in i.

**two_point_correlation**

Compute the two-point correlation function

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] A array of points to query. Last dimension should match dimension of training data.
- **r** [array_like] A one-dimensional array of distances
- **dualtree** [boolean (default = False)] If true, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

**Returns**

- **counts** [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

### 7.30.2 sklearn.neighbors.DistanceMetric

**class** sklearn.neighbors.DistanceMetric

DistanceMetric class

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the get_metric class method and the metric string identifier (see below). For example, to use the Euclidean distance:

```python
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2],
      [3, 4, 5]]
>>> dist.pairwise(X)
array([[ 0. , 5.19615242],
       [ 5.19615242,  0. ]])
```

**Available Metrics**

The following lists the string metric identifiers and the associated distance metric classes:

**Metrics intended for real-valued vector spaces:**
### Metrics intended for two-dimensional vector spaces:
Note that the haversine distance metric requires data in the form of [latitude, longitude] and both inputs and outputs are in units of radians.

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;haversine&quot;</td>
<td>HaversineDistance</td>
<td>2 arcsin(sqrt(sin^2(0.5<em>dx) + cos(x1)cos(x2)sin^2(0.5</em>dy))))</td>
</tr>
</tbody>
</table>

### Metrics intended for integer-valued vector spaces:
Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;hamming&quot;</td>
<td>HammingDistance</td>
<td>N_unequal(x, y) / N_tot</td>
</tr>
<tr>
<td>&quot;canberra&quot;</td>
<td>CanberraDistance</td>
<td>sum(</td>
</tr>
<tr>
<td>&quot;braycurtis&quot;</td>
<td>BrayCurtisDistance</td>
<td>sum(</td>
</tr>
</tbody>
</table>

### Metrics intended for boolean-valued vector spaces:
Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- **N**: number of dimensions
- **NTT**: number of dims in which both values are True
- **NTF**: number of dims in which the first value is True, second is False
- **NFT**: number of dims in which the first value is False, second is True
- **NFF**: number of dims in which both values are False
- **NNEQ**: number of non-equal dimensions, NNEQ = NTF + NFT
- **NNZ**: number of nonzero dimensions, NNZ = NTF + NFT + NTT
### Distance Functions

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;jaccard&quot;</td>
<td>JaccardDistance</td>
<td>NNEQ / NNZ</td>
</tr>
<tr>
<td>&quot;matching&quot;</td>
<td>MatchingDistance</td>
<td>NNEQ / N</td>
</tr>
<tr>
<td>&quot;dice&quot;</td>
<td>DiceDistance</td>
<td>NNEQ / (NTT + NNZ)</td>
</tr>
<tr>
<td>&quot;kulsinski&quot;</td>
<td>KulsinskiDistance</td>
<td>(NNEQ + N - NTT) / (NNEQ + N)</td>
</tr>
<tr>
<td>&quot;rogerstanimoto&quot;</td>
<td>RogersTanimotoDistance</td>
<td>2 * NNEQ / (N + NNEQ)</td>
</tr>
<tr>
<td>&quot;russellrao&quot;</td>
<td>RussellRaoDistance</td>
<td>NNZ / N</td>
</tr>
<tr>
<td>&quot;sokalmichener&quot;</td>
<td>SokalMichenerDistance</td>
<td>2 * NNEQ / (N + NNEQ)</td>
</tr>
<tr>
<td>&quot;sokalsneath&quot;</td>
<td>SokalSneathDistance</td>
<td>NNEQ / (NNEQ + 0.5 * NTT)</td>
</tr>
</tbody>
</table>

### User-defined distance:

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>args</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pyfunc&quot;</td>
<td>PyFuncDistance</td>
<td>func</td>
</tr>
</tbody>
</table>

Here `func` is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the BallTree, the distance must be a true metric: i.e. it must satisfy the following properties:

1. Non-negativity: \( d(x, y) \geq 0 \)
2. Identity: \( d(x, y) = 0 \) if and only if \( x == y \)
3. Symmetry: \( d(x, y) = d(y, x) \)
4. Triangle Inequality: \( d(x, y) + d(y, z) \geq d(x, z) \)

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

### Methods

- **dist_to_rdist()** Convert the true distance to the reduced distance.
- **get_metric()** Get the given distance metric from the string identifier.
- **pairwise()** Compute the pairwise distances between \( X \) and \( Y \)
- **rdist_to_dist()** Convert the Reduced distance to the true distance.

#### __init__(self, /, *args, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

#### dist_to_rdist()

Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

#### get_metric()

Get the given distance metric from the string identifier.

See the docstring of DistanceMetric for a list of available metrics.

#### Parameters

- **metric** [string or class name] The distance metric to use
**kwargs additional arguments will be passed to the requested metric

`pairwise()`
Compute the pairwise distances between X and Y

This is a convenience routine for the sake of testing. For many metrics, the utilities in `scipy.spatial.distance.cdist` and `scipy.spatial.distance.pdist` will be faster.

**Parameters**

- `X` [array_like] Array of shape (Nx, D), representing Nx points in D dimensions.
- `Y` [array_like (optional)] Array of shape (Ny, D), representing Ny points in D dimensions.
  If not specified, then Y=X.

**Returns**

- `dist` [ndarray] The shape (Nx, Ny) array of pairwise distances between points in X and Y.

`rdist_to_dist()`
Convert the Reduced distance to the true distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

### 7.30.3 sklearn.neighbors.KDTree

**class sklearn.neighbors.KDTree**

KDTree for fast generalized N-point problems

`KDTree(X, leaf_size=40, metric='minkowski', **kwargs)`

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

- `leaf_size` [positive integer (default = 40)] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

- `metric` [string or DistanceMetric object] the distance metric to use for the tree. Default=’minkowski’ with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. kd_tree.valid_metrics gives a list of the metrics which are valid for KDTree.

Additional keywords are passed to the distance metric class.

**Note:** Callable functions in the metric parameter are NOT supported for KDTree and Ball Tree. Function call overhead will result in very poor performance.

**Attributes**

- `data` [memory view] The training data
Examples

Query for k-nearest neighbors

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)  # doctest: +SKIP
>>> dist, ind = tree.query(X[:1], k=3)  # doctest: +SKIP
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```python
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)  # doctest: +SKIP
>>> s = pickle.dumps(tree)  # doctest: +SKIP
>>> tree_copy = pickle.loads(s)  # doctest: +SKIP
>>> dist, ind = tree_copy.query(X[:1], k=3)  # doctest: +SKIP
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Query for neighbors within a given radius

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)  # doctest: +SKIP
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)  # doctest: +SKIP
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```python
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = KDTree(X)  # doctest: +SKIP
>>> tree.kernel_density(X[3], h=0.1, kernel='gaussian')
array([ 6.94114669, 7.83281226, 7.2071716])
```

Compute a two-point auto-correlation function

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = KDTree(X)  # doctest: +SKIP
```

(continues on next page)
Methods

- `kernel_density(self, X, h[, kernel, atol, ...])`: Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

- `query(X[, k, return_distance, dualtree, ...])`: query the tree for the k nearest neighbors

- `query_radius()`: query_radius(self, X, r, count_only = False):

- `two_point_correlation()`: Compute the two-point correlation function

```python
>>> tree.two_point_correlation(X, r)
array([ 30, 62, 278, 580, 820])
```

```python
__init__(self, /, *args, **kwargs)
 Initialize self. See help(type(self)) for accurate signature.

kernel_density(self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth_first=True, return_log=False)
 Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

Parameters

- **X** [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
- **h** [float] the bandwidth of the kernel
- **kernel** [string] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’
- **atol, rtol** [float (default = 0)] Specify the desired relative and absolute tolerance of the result. If the true result is K_true, then the returned result K_ret satisfies abs(K_true - K_ret) < atol + rtol * K_ret The default is zero (i.e. machine precision) for both.
- **breadth_first** [boolean (default = False)] if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.
- **return_log** [boolean (default = False)] return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns

- **density** [ndarray] The array of (log)-density evaluations, shape = X.shape[:,-1]

query(X, k=1, return_distance=True, dualtree=False, breadth_first=False)
 query the tree for the k nearest neighbors

Parameters
X [array-like of shape (n_samples, n_features)] An array of points to query

k [integer (default = 1)] The number of nearest neighbors to return

return_distance [boolean (default = True)] if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree [boolean (default = False)] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first [boolean (default = False)] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results [boolean (default = True)] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns

i [if return_distance == False]

(d,i) [if return_distance == True]

d [array of doubles - shape: x.shape[::1] + (k,)] each entry gives the list of distances to the neighbors of the corresponding point

i [array of integers - shape: x.shape[::1] + (k,)] each entry gives the list of indices of neighbors of the corresponding point

query_radius ()

query_radius(self, X, r, count_only = False):

query the tree for neighbors within a radius r

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query

r [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[::1] if different radii are desired for each point.

return_distance [boolean (default = False)] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be calculated explicitly for return_distance=False. Results are not sorted by default: see sort_results keyword.

count_only [boolean (default = False)] if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

sort_results [boolean (default = False)] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns

count [if count_only == True]

ind [if count_only == False and return_distance == False]

(ind, dist) [if count_only == False and return_distance == True]
count [array of integers, shape = X.shape[:-1]] each entry gives the number of neighbors within a distance r of the corresponding point.

ind [array of objects, shape = X.shape[:-1]] each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

dist [array of objects, shape = X.shape[:-1]] each element is a numpy double array listing the distances corresponding to indices in ind.

two_point_correlation()  
Compute the two-point correlation function

Parameters

- X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
- r [array_like] A one-dimensional array of distances
- dualtree [boolean (default = False)] If true, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns

- counts [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

7.30.4 sklearn.neighbors.KernelDensity

class sklearn.neighbors.KernelDensity (bandwidth=1.0, algorithm='auto', kernel='gaussian', metric='euclidean', atol=0, rtol=0, breadth_first=True, leaf_size=40, metric_params=None)

Kernel Density Estimation.
Read more in the User Guide.

Parameters

- bandwidth [float] The bandwidth of the kernel.
- algorithm [str] The tree algorithm to use. Valid options are ['kd_tree','ball_tree','auto']. Default is 'auto'.
- kernel [str] The kernel to use. Valid kernels are ['gaussian','tophat','epanechnikov','exponential','linear','cosine']. Default is 'gaussian'.
- metric [str] The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of BallTree and KDTree for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is 'euclidean'.
- atol [float] The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.
- rtol [float] The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8.
- breadth_first [bool] If true (default), use a breadth-first approach to the problem. Otherwise, use a depth-first approach.
leaf_size  [int] Specify the leaf size of the underlying tree. See BallTree or KDTree for details. Default is 40.

metric_params  [dict] Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of BallTree or KDTree.

See also:

sklearn.neighbors.KDTree  K-dimensional tree for fast generalized N-point problems.

sklearn.neighbors.BallTree  Ball tree for fast generalized N-point problems.

Examples

Compute a gaussian kernel density estimate with a fixed bandwidth. >>> import numpy as np >>> rng = np.random.RandomState(42) >>> X = rng.random_sample((100, 3)) >>> kde = KernelDensity(kernel='gaussian', bandwidth=0.5).fit(X) >>> log_density = kde.score_samples(X[:3]) >>> log_density array([-1.52955942, -1.51462041, -1.60244657])

Methods

fit(self, X[, y, sample_weight])  Fit the Kernel Density model on the data.

generate_params(self[, deep])  Get parameters for this estimator.

generate_sample(self[, n_samples, random_state])  Generate random samples from the model.

score(self, X[, y])  Compute the total log probability density under the model.

score_samples(self, X)  Evaluate the log density model on the data.

set_params(self, **params)  Set the parameters of this estimator.

__init__ (self, bandwidth=1.0, algorithm='auto', kernel='gaussian', metric='euclidean', atol=0, rtol=0, breadth_first=True, leaf_size=40, metric_params=None)  Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None, sample_weight=None)  Fit the Kernel Density model on the data.

Parameters

X  [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

y  [None] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

sample_weight  [array_like, shape (n_samples,), optional] List of sample weights attached to the data X.

Returns

self  [object] Returns instance of object.

generate_params (self, deep=True)  Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [mapping of string to any] Parameter names mapped to their values.

sample (self, n_samples=1, random_state=None)
Generate random samples from the model.
Currently, this is implemented only for gaussian and tophat kernels.

Parameters

n_samples [int, optional] Number of samples to generate. Defaults to 1.

random_state [int, RandomState instance or None. default to None] If int, random_state is
the seed used by the random number generator; If RandomState instance, random_state is
the random number generator; If None, the random number generator is the RandomState
instance used by np.random.

Returns

X [array_like, shape (n_samples, n_features)] List of samples.

score (self, X, y=None)
Compute the total log probability density under the model.

Parameters

X [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points.
Each row corresponds to a single data point.

y [None] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

logprob [float] Total log-likelihood of the data in X. This is normalized to be a probability
density, so the value will be low for high-dimensional data.

score_samples (self, X)
Evaluate the log density model on the data.

Parameters

X [array_like, shape (n_samples, n_features)] An array of points to query. Last dimension
should match dimension of training data (n_features).

Returns

density [ndarray, shape (n_samples,)] The array of log(density) evaluations. These are nor-
malized to be probability densities, so values will be low for high-dimensional data.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.
Examples using `sklearn.neighbors.KernelDensity`

- Kernel Density Estimation
- Kernel Density Estimate of Species Distributions
- Simple 1D Kernel Density Estimation

### 7.30.5 `sklearn.neighbors.KNeighborsClassifier`

class `sklearn.neighbors.KNeighborsClassifier`(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Classifier implementing the k-nearest neighbors vote.

Read more in the User Guide.

**Parameters**

- **n_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for kneighbors queries.

- **weights** [str or callable, optional (default = ‘uniform’)] weight function used in prediction. Possible values:
  - ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  - [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

- **algorithm** [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

- **metric** [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a Glossary, in which case only “nonzero” elements may be considered neighbors.
**metric_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. Doesn’t affect fit method.

**Attributes**

- **classes_** [array of shape (n_classes,)] Class labels known to the classifier
- **effective_metric_** [string or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.
- **effective_metric_params_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.
- **outputs_2d_** [bool] False when y’s shape is (n_samples,) or (n_samples, 1) during fit otherwise True.

See also:

- RadiusNeighborsClassifier
- KNeighborsRegressor
- RadiusNeighborsRegressor
- NearestNeighbors

**Notes**

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor k+1 and k, have identical distances but different labels, the results will depend on the ordering of the training data.

**Examples**

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[0.66666667 0.33333333]]
```

### `__init__` (self, n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

### `fit` (self, X, y)

Fit the model using X as training data and y as target values

#### Parameters

- **X** ([array-like, sparse matrix, BallTree, KDTree]) Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.
- **y** ([array-like, sparse matrix]) Target values of shape = [n_samples] or [n_samples, n_outputs]

### `get_params` (self, deep=True)

Get parameters for this estimator.

#### Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

### `kneighbors` (self, X=None, n_neighbors=None, return_distance=True)

Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

#### Parameters

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).
- **return_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

#### Returns

- **neigh_dist** [array, shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True
**neigh_ind**  [array, shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
code
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)

>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
code
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])...
```

**kneighbors_graph**  *(self, X=None, n_neighbors=None, mode='connectivity')*

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X**  [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **n_neighbors**  [int] Number of neighbors for each sample. (default is value passed to the constructor).

- **mode**  [‘connectivity’, ‘distance’], optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A**  [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

*NearestNeighbors.radius_neighbors_graph*

**Examples**

```python
code
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
```
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])

**predict** *(self, X)*

Predict the class labels for the provided data.

**Parameters**

X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed'] Test samples.

**Returns**

y [array of shape [n_queries] or [n_queries, n_outputs]] Class labels for each data sample.

**predict_proba** *(self, X)*

Return probability estimates for the test data X.

**Parameters**

X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed'] Test samples.

**Returns**

p [array of shape = [n_queries, n_classes], or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

**score** *(self, X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels. In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.
Examples using `sklearn.neighbors.KNeighborsClassifier`

- Classifier comparison
- Plot the decision boundaries of a VotingClassifier
- Nearest Neighbors Classification
- Caching nearest neighbors
- Comparing Nearest Neighbors with and without Neighborhood Components Analysis
- Dimensionality Reduction with Neighborhood Components Analysis
- Digits Classification Exercise
- Classification of text documents using sparse features

7.30.6 `sklearn.neighbors.KNeighborsRegressor`

```python
class sklearn.neighbors.KNeighborsRegressor(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)
```

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the User Guide.

New in version 0.9.

Parameters

- `n_neighbors` [int, optional (default = 5)] Number of neighbors to use by default for `kneighbors` queries.
- `weights` [str or callable] weight function used in prediction. Possible values:
  - ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  - [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

- `algorithm` [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use `BallTree`
  - ‘kd_tree’ will use `KDTree`
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.
leaf_size [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a Glossary, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, optional (default = None)] Additional keyword arguments for the metric function.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. Doesn’t affect fit method.

Attributes

effective_metric_ [string or callable] The distance metric to use. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

__init__(self, n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Fit the model using X as training data and y as target values

Parameters

- X ([array-like, sparse matrix, BallTree, KDTree]) Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.
- y ([array-like, sparse matrix])

Target values, array of float values, shape = [n_samples] or [n_samples, n_outputs]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

kneighbors (self, X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

Parameters

- X ([array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed']) The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- n_neighbors [int] Number of neighbors to get (default is the value passed to the constructor).
return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned.

Returns

neigh_dist [array, shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True

neigh_ind [array, shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]...])
```

kneighbors_graph (self, X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters

X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors [int] Number of neighbors for each sample. (default is value passed to the constructor).

mode [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

A [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

NearestNeighbors.radius_neighbors_graph
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

**predict** *(self, X)*

Predict the target for the provided data

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] Test samples.

**Returns**

- **y** [array of int, shape = [n_queries] or [n_queries, n_outputs]] Target values

**score** *(self, X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,), or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. $y$.

**Notes**

The $R^2$ score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set_params** *(self, **params)*

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

`**params [dict] Estimator parameters.**`

**Returns**

`self [object] Estimator instance.`

**Examples using sklearn.neighbors.KNeighborsRegressor**

- Face completion with a multi-output estimators
- Imputing missing values with variants of IterativeImputer
- Nearest Neighbors regression

### 7.30.7 sklearn.neighbors.KNeighborsTransformer

```python
class sklearn.neighbors.KNeighborsTransformer (mode='distance', n_neighbors=5, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1)
```

Transform X into a (weighted) graph of k nearest neighbors

The transformed data is a sparse graph as returned by kneighbors_graph.

Read more in the User Guide.

New in version 0.22.

**Parameters**

- `mode [‘distance’, ‘connectivity’], default=’distance’` Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

- `n_neighbors [int, default=5]` Number of neighbors for each sample in the transformed sparse graph. For compatibility reasons, as each sample is considered as its own neighbor, one extra neighbor will be computed when mode == ‘distance’. In this case, the sparse graph contains (n_neighbors + 1) neighbors.

- `algorithm [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’` Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- `leaf_size [int, default=30]` Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
**metric** [string or callable, default='minkowski'] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.

**p** [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

**metric_params** [dict, default=None] Additional keyword arguments for the metric function.

**n_jobs** [int, default=1] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

---

### Examples

```python
>>> from sklearn.manifold import Isomap
>>> from sklearn.neighbors import KNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline

>>> estimator = make_pipeline(
...     KNeighborsTransformer(n_neighbors=5, mode='distance'),
...     Isomap(neighbors_algorithm='precomputed'))
```

---

---

```python
__init__(self, mode='distance', n_neighbors=5, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit(self, X, y=None)
```
Fit the model using X as training data

**Parameters**

- **X**: [array-like, sparse matrix, BallTree, KDTree] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

**fit_transform**(self, X, y=None)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X**: [array-like of shape (n_samples, n_features)] Training set.
- **y**: [ignored]

**Returns**

- **Xt**: [CSR sparse graph of shape (n_samples, n_samples)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit.

**get_params**(self, deep=True)
Get parameters for this estimator.

**Parameters**

- **deep**: [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**: [mapping of string to any] Parameter names mapped to their values.

**kneighbors**(self, X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

**Parameters**

- **X**: [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors**: [int] Number of neighbors to get (default is the value passed to the constructor).
- **return_distance**: [boolean, optional. Defaults to True.] If False, distances will not be returned

**Returns**

- **neigh_dist**: [array, shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True
- **neigh_ind**: [array, shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]
```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1.],
       [2]])...
```

**kneighbors_graph** *(self, X=None, n_neighbors=None, mode='connectivity')*
Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).
- **mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

**See also:**
- **NearestNeighbors.radius_neighbors_graph**

**Examples**

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

**set_params** *(self, **params)*
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform** (self, X)

Computes the (weighted) graph of Neighbors for points in X

**Parameters**

X [array-like of shape (n_samples_transform, n_features)] Sample data

**Returns**

Xt [CSR sparse graph of shape (n_samples_transform, n_samples_fit)] X[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit.

Examples using sklearn.neighbors.KNeighborsTransformer

- Approximate nearest neighbors in TSNE

### 7.30.8 sklearn.neighbors.LocalOutlierFactor

**class** sklearn.neighbors.LocalOutlierFactor (n_neighbors=20, algorithm='auto',
leaf_size=30, metric='minkowski', p=2,
metric_params=None, contamination='auto', novelty=False, n_jobs=None)

Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by k-nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

New in version 0.19.

**Parameters**

n_neighbors [int, optional (default=20)] Number of neighbors to use by default for kneighbors queries. If n_neighbors is larger than the number of samples provided, all samples will be used.

algorithm [[‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], optional] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf_size** [int, optional (default=30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [string or callable, default ‘minkowski’] metric used for the distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics: https://docs.scipy.org/doc/scipy/reference/spatial.distance.html

**p** [integer, optional (default=2)] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

**metric_params** [dict, optional (default=None)] Additional keyword arguments for the metric function.

**contamination** ['auto' or float, optional (default='auto')] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the scores of the samples.

• if ‘auto’, the threshold is determined as in the original paper,

• if a float, the contamination should be in the range [0, 0.5].

Changed in version 0.22: The default value of contamination changed from 0.1 to 'auto'.

**novelty** [boolean, default False] By default, LocalOutlierFactor is only meant to be used for outlier detection (novelty=False). Set novelty to True if you want to use LocalOutlierFactor for novelty detection. In this case be aware that that you should only use predict, decision_function and score_samples on new unseen data and not on the training set.

**n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See **Glossary** for more details.

**Attributes**

**negative_outlier_factor_** [numpy array, shape (n_samples,)]: The opposite LOF of the training samples. The higher, the more normal. Inliers tend to have a LOF score close to 1
The local outlier factor (LOF) of a sample captures its supposed ‘degree of abnormality’. It is the average of the ratio of the local reachability density of a sample and those of its k-nearest neighbors.

**n_neighbors_** [integer] The actual number of neighbors used for `kneighbors` queries.

**offset_** [float] Offset used to obtain binary labels from the raw scores. Observations having a negative_outlier_factor smaller than `offset_` are detected as abnormal. The offset is set to -1.5 (inliers score around -1), except when a contamination parameter different than “auto” is provided. In that case, the offset is defined in such a way we obtain the expected number of outliers in training.

### References

[Rca479bb49841-1]

### Examples

```python
>>> import numpy as np
>>> from sklearn.neighbors import LocalOutlierFactor
>>> X = [[-1.1], [0.2], [101.1], [0.3]]
>>> clf = LocalOutlierFactor(n_neighbors=2)
>>> clf.fit_predict(X)
array([1, 1, -1, 1])
>>> clf.negative_outlier_factor_
array([-0.9821..., -1.0370..., -73.3697..., -0.9821...])
```

### Methods

- `fit(self, X[, y])` Fit the model using X as training data.
- `get_params(self[, deep])` Get parameters for this estimator.
- `kneighbors(self[, X, n_neighbors,...])` Finds the K-neighbors of a point.
- `kneighbors_graph(self[, X, n_neighbors,...])` Computes the (weighted) graph of k-Neighbors for points in X.
- `set_params(self, **params)` Set the parameters of this estimator.

```
__init__(self, n_neighbors=20, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, contamination='auto', novelty=False, n_jobs=None)
```

Initialize self. See help(type(self)) for accurate signature.

### property decision_function

Shifted opposite of the Local Outlier Factor of X.

Bigger is better, i.e. large values correspond to inliers.

The shift offset allows a zero threshold for being an outlier. Only available for novelty detection (when novelty is set to True). The argument X is supposed to contain **new data**: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point.

### Parameters
X [array-like, shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

Returns

shifted_opposite_lof_scores [array, shape (n_samples,)] The shifted opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

fit (self, X, y=None)
Fit the model using X as training data.

Parameters

X [[array-like, sparse matrix, BallTree, KDTree]] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y [Ignored] not used, present for API consistency by convention.

Returns

self [object]

property fit_predict
"Fits the model to the training set X and returns the labels.
Label is 1 for an inlier and -1 for an outlier according to the LOF score and the contamination parameter.

Parameters

X [array-like, shape (n_samples, n_features), default=None] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

y [Ignored] not used, present for API consistency by convention.

Returns

is_inlier [array, shape (n_samples,)] Returns -1 for anomalies/outliers and 1 for inliers.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

kneighbors (self, X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

Parameters

X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors [int] Number of neighbors to get (default is the value passed to the constructor).

return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned.

Returns
**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])...
```

### kneighbors_graph

(kneighbors_graph (self, X=None, n_neighbors=None, mode='connectivity'))

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **n_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

- **mode** [‘connectivity’, ‘distance’], optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

- **NearestNeighbors.radius_neighbors_graph**

### Examples
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])

property predict
Predict the labels (1 inlier, -1 outlier) of X according to LOF.

This method allows to generalize prediction to *new observations* (not in the training set). Only available for novelty detection (when novelty is set to True).

Parameters

X [array-like, shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

Returns

is_inlier [array, shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

property score_samples
Opposite of the Local Outlier Factor of X.

It is the opposite as bigger is better, i.e. large values correspond to inliers.

Only available for novelty detection (when novelty is set to True). The argument X is supposed to contain *new data*: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point. The score_samples on training data is available by considering the the negative_outlier_factor_attribute.

Parameters

X [array-like, shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

Returns

opposite_lof_scores [array, shape (n_samples,)] The opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.
Examples using `sklearn.neighbors.LocalOutlierFactor`

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Outlier detection with Local Outlier Factor (LOF)
- Novelty detection with Local Outlier Factor (LOF)

### 7.30.9 `sklearn.neighbors.RadiusNeighborsClassifier`

class `sklearn.neighbors.RadiusNeighborsClassifier`(radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', outlier_label=None, metric_params=None, n_jobs=None, **kwargs)

Classifier implementing a vote among neighbors within a given radius

Read more in the [User Guide](#).

**Parameters**

- **radius** [float, optional (default = 1.0)] Range of parameter space to use by default for `radius_neighbors` queries.
- **weights** [str or callable] weight function used in prediction. Possible values:
  - `uniform` : uniform weights. All points in each neighborhood are weighted equally.
  - `distance` : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  - [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

- **algorithm** [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:
  - `ball_tree` will use `BallTree`
  - `kd_tree` will use `KDTree`
  - `brute` will use a brute-force search.
  - `auto` will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

- **metric** [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric.

See the documentation of the DistanceMetric class for a list of available metrics. If metric
is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a *[Glossary](#)*, in which case only “nonzero” elements may be considered neighbors.

**outlier_label**  [[(manual label, ‘most_frequent’), optional (default = None)] label for outlier samples (samples with no neighbors in given radius).

- manual label: str or int label (should be the same type as y) or list of manual labels if multi-output is used.
- ‘most_frequent’ : assign the most frequent label of y to outliers.
- None : when any outlier is detected, ValueError will be raised.

**metric_params**  [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n_jobs**  [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a *[joblib.parallel_backend](#)* context. -1 means using all processors. See *[Glossary](#)* for more details.

**Attributes**

- **classes_**  [array of shape (n_classes,)] Class labels known to the classifier.
- **effective_metric_**  [string or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.
- **effective_metric_params_**  [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_attribute is set to ‘minkowski’.
- **outputs_2d_**  [bool] False when y’s shape is (n_samples,) or (n_samples, 1) during fit otherwise True.

- [RadiusNeighborsRegressor](#)
- [KNeighborsRegressor](#)
- [NearestNeighbors](#)

**Notes**

See *[Nearest Neighbors](#)* in the online documentation for a discussion of the choice of algorithm and leaf_size.

**Examples**

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsClassifier
>>> neigh = RadiusNeighborsClassifier(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsClassifier(...)
```
Methods

- **fit**(self, X, y)  
  Fit the model using X as training data and y as target values

- **get_params**(self[, deep])  
  Get parameters for this estimator.

- **predict**(self, X)  
  Predict the class labels for the provided data.

- **predict_proba**(self, X)  
  Return probability estimates for the test data X.

- **radius_neighbors**(self[, X, radius, ...])  
  Finds the neighbors within a given radius of a point or points.

- **radius_neighbors_graph**(self[, X, radius, ...])  
  Computes the (weighted) graph of Neighbors for points in X.

- **score**(self, X, y[, sample_weight])  
  Return the mean accuracy on the given test data and labels.

- **set_params**(self, **params)  
  Set the parameters of this estimator.

**__init__**(self, radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', outlier_label=None, metric_params=None, n_jobs=None, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y)

Fit the model using X as training data and y as target values

**Parameters**

- **X** ([array-like, sparse matrix, BallTree, KDTree]) Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

- **y** ([array-like, sparse matrix]) Target values of shape = [n_samples] or [n_samples, n_outputs]

**get_params**(self, deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict**(self, X)

Predict the class labels for the provided data.

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’) Test samples.

**Returns**

- **y** [array of shape [n_queries] or [n_queries, n_outputs]] Class labels for each data sample.
**predict_proba** *(self, X)*

Return probability estimates for the test data X.

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed'] Test samples.

**Returns**

- **p** [array of shape = [n_queries, n_classes], or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

**radius_neighbors** *(self, X=None, radius=None, return_distance=True, sort_results=False)*

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

**Parameters**

- **X** [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).
- **return_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.
- **sort_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

New in version 0.22.

**Returns**

- **neigh_dist** [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.
- **neigh_ind** [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

**Notes**

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.

**Examples**

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5  0.5]
>>> print(np.asarray(rng[1][0]))
[1  2]

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

radius_neighbors_graph (self, X=None, radius=None, mode='connectivity', sort_results=False)
Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Parameters

X [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float] Radius of neighborhoods. (default is the value passed to the constructor).

mode [{'connectivity', 'distance'}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

sort_results [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

New in version 0.22.

Returns

A [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

kneighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
```

(continues on next page)
score (self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

- X [array-like of shape (n_samples, n_features)] Test samples.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it's possible to update each component
of a nested object.

Parameters

- **params [dict] Estimator parameters.

Returns

7.30.10 sklearn.neighbors.RadiusNeighborsRegressor

class sklearn.neighbors.RadiusNeighborsRegressor (radius=1.0, weights='uniform',
algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None,
**kwargs)

Regression based on neighbors within a fixed radius.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the User Guide.

New in version 0.9.

Parameters

- radius [float, optional (default = 1.0)] Range of parameter space to use by default for
  radius_neighbors queries.
- weights [str or callable] weight function used in prediction. Possible values:
  - 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
  - 'distance' : weight points by the inverse of their distance. in this case, closer neighbors
    of a query point will have a greater influence than neighbors which are further away.
• [callable] : a user-defined function which accepts an array of distances, and returns an
array of the same shape containing the weights.

Uniform weights are used by default.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the
nearest neighbors:
• ‘ball_tree’ will use BallTree
• ‘kd_tree’ will use KDTree
• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed
to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect
the speed of the construction and query, as well as the memory required to store the tree.
The optimal value depends on the nature of the problem.

p [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this
is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For
arbitrary p, minkowski_distance (l_p) is used.

metric [string or callable, default ‘minkowski’] the distance metric to use for the tree. The
default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric.
See the documentation of the DistanceMetric class for a list of available metrics. If metric
is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X
may be a Glossary, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, optional (default = None)] Additional keyword arguments for the metric
function.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors
search. None means 1 unless in a joblib.parallel_backend context. -1 means
using all processors. See Glossary for more details.

Attributes

effective_metric_ [string or callable] The distance metric to use. It will be same as the metric
parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’
and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For
most metrics will be same with metric_params parameter, but may also contain the p
parameter value if the effective_metric__attribute is set to ‘minkowski’.

Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

Methods

- `fit(self, X, y)`
  Fit the model using X as training data and y as target values

- `get_params(self[, deep])`
  Get parameters for this estimator.

- `predict(self, X)`
  Predict the target for the provided data

- `radius_neighbors(self[, X, radius, ...])`
  Finds the neighbors within a given radius of a point or points.

- `radius_neighbors_graph(self[, X, radius, ...])`
  Computes the (weighted) graph of Neighbors for points in X

- `score(self, X, y[, sample_weight])`
  Return the coefficient of determination $R^2$ of the prediction.

- `set_params(self, **params)`
  Set the parameters of this estimator.

__init__(self, radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

- `fit (self, X, y)`
  Fit the model using X as training data and y as target values

  **Parameters**

  - `X`
    [array-like, sparse matrix, BallTree, KDTree] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

  - `y`
    [array-like, sparse matrix]

  **Target values, array of float values, shape = [n_samples] or [n_samples, n_outputs]

- `get_params (self, deep=True)`
  Get parameters for this estimator.

  **Parameters**

  - `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict the target for the provided data

Parameters

X [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] Test samples.

Returns

y [array of float, shape = [n_queries] or [n_queries, n_outputs]] Target values

radius_neighbors (self, X=None, radius=None, return_distance=True, sort_results=False)
Finds the neighbors within a given radius of a point or points.
Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.
The result points are not necessarily sorted by distance to their query point.

Parameters

X [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned.

sort_results [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

New in version 0.22.

Returns

neigh_dist [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

neigh_ind [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

7.30. sklearn.neighbors: Nearest Neighbors
The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** (self, X=None, radius=None, mode='connectivity', sort_results=False)
Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).
- **mode** [('connectivity', 'distance'), optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.
- **sort_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

**Returns**

- **A** [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

- **kneighbors_graph**

**Examples**

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 1., 0.]])
```
score (self, X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

7.30.11 sklearn.neighbors.RadiusNeighborsTransformer

class sklearn.neighbors.RadiusNeighborsTransformer (mode='distance', radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1)

Transform X into a (weighted) graph of neighbors nearer than a radius

The transformed data is a sparse graph as returned by radius_neighbors_graph.
Parameters

mode [\{'distance', 'connectivity'\}, default='distance'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

radius [float, default=1.] Radius of neighborhood in the transformed sparse graph.

algorithm [\{'auto', 'ball_tree', 'kd_tree', 'brute'\}, default='auto'] Algorithm used to compute the nearest neighbors:
  • ‘ball_tree’ will use BallTree
  • ‘kd_tree’ will use KDTree
  • ‘brute’ will use a brute-force search.
  • ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric [string or callable, default='minkowski'] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=1] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.
Examples

```python
>>> from sklearn.cluster import DBSCAN
>>> from sklearn.neighbors import RadiusNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline

>>> estimator = make_pipeline(
...    RadiusNeighborsTransformer(radius=42.0, mode='distance'),
...    DBSCAN(min_samples=30, metric='precomputed'))
```

```python
__init__(self, mode='distance', radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, X, y=None)
```

Fit the model using X as training data

Parameters

- **X** : [array-like, sparse matrix, BallTree, KDTree] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

```python
fit_transform (self, X, y=None)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** : [array-like of shape (n_samples, n_features)] Training set.
- **y** : [ignored]

Returns

- **Xt** : [CSR sparse graph, shape (n_samples, n_samples)] X[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit.

`get_params (self, deep=True)`

Get parameters for this estimator.

Parameters

- **deep** : [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [mapping of string to any] Parameter names mapped to their values.

radius_neighbors (self, X=None, radius=None, return_distance=True, sort_results=False)
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

X [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned.

sort_results [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

New in version 0.22.

Returns

neigh_dist [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

neigh_ind [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
```
(continues on next page)
The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** (self, X=None, radius=None, mode='connectivity', sort_results=False)

Computes the (weighted) graph of Neighbors for points in X.

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).
- **mode** ['connectivity', 'distance'], optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.
- **sort_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

New in version 0.22.

**Returns**

- **A** [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

**kneighbors_graph**

**Examples**

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**set_params** (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(self, X)
Computes the (weighted) graph of Neighbors for points in X

Parameters

X [array-like of shape (n_samples_transform, n_features)] Sample data

Returns

Xt [CSR sparse graph of shape (n_samples_transform, n_samples_fit)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit.

7.30.12 sklearn.neighbors.NearestCentroid

class sklearn.neighbors.NearestCentroid(metric='euclidean', shrink_threshold=None)
Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the User Guide.

Parameters

metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.pairwise_distances for its metric parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to the metric) of all samples that belong to that particular class are minimized. If the “manhattan” metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.

shrink_threshold [float, optional (default = None)] Threshold for shrinking centroids to remove features.

Attributes

centroids_ [array-like of shape (n_classes, n_features)] Centroid of each class.

classes_ [array of shape (n_classes,)] The unique classes labels.

See also:

sklearn.neighbors.KNeighborsClassifier nearest neighbors classifier

Notes

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.
References

Examples

```python
>>> from sklearn.neighbors import NearestCentroid
>>> import numpy as np

>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = NearestCentroid()
>>> clf.fit(X, y)
NearestCentroid()
>>> print(clf.predict([[0.8, -1]]))
[1]
```

Methods

- `fit(self, X, y)` Fit the NearestCentroid model according to the given training data.
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, X)` Perform classification on an array of test vectors X.
- `score(self, X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(self, **params)` Set the parameters of this estimator.

```python
__init__(self, metric='euclidean', shrink_threshold=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Fit the NearestCentroid model according to the given training data.

Parameters

- `X` [array-like, sparse matrix] of shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the number of features. Note that centroid shrinking cannot be used with sparse matrices.
- `y` [array, shape = [n_samples]] Target values (integers)

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Perform classification on an array of test vectors X.
```
The predicted class $C$ for each sample in $X$ is returned.

**Parameters**

$X$ [array-like of shape (n_samples, n_features)]

**Returns**

$C$ [ndarray of shape (n_samples,)]

**Notes**

If the metric constructor parameter is “precomputed”, $X$ is assumed to be the distance matrix between the data to be predicted and $self.centroids_.$

**score**(self, $X$, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

$X$ [array-like of shape (n_samples, n_features)] Test samples.

$y$ [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for $X$.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of $self.predict(X)$ wrt. $y$.

**set_params**(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form $<component>__<parameter>$ so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**Examples using sklearn.neighbors.NearestCentroid**

- **Nearest Centroid Classification**
- **Classification of text documents using sparse features**

**7.30.13 sklearn.neighbors.NearestNeighbors**

**class** sklearn.neighbors.NearestNeighbors(n_neighbors=5, radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=None)

Unsupervised learner for implementing neighbor searches.

Read more in the User Guide.
New in version 0.9.

Parameters

- **n_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for `kneighbors` queries.
- **radius** [float, optional (default = 1.0)] Range of parameter space to use by default for `radius_neighbors` queries.
- **algorithm** [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

  Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **metric** [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a `Glossary`, in which case only “nonzero” elements may be considered neighbors.

- **p** [integer, optional (default = 2)] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

- **metric_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

- **n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

Attributes

- **effective_metric_** [string] Metric used to compute distances to neighbors.

- **effective_metric_params_** [dict] Parameters for the metric used to compute distances to neighbors.

Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

Examples

```python
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]

>>> neigh = NearestNeighbors(2, 0.4)
>>> neigh.fit(samples)
NearestNeighbors(...)

>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
array([[2, 0]])

>>> nbrs = neigh.radius_neighbors([[0, 0, 1.3]], 0.4, return_distance=False)
>>> np.asarray(nbrs[0][0])
array(2)
```

</tr>
</tbody>
</table>

__init__ (self, n_neighbors=5, radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Fit the model using X as training data

Parameters

X [[array-like, sparse matrix, BallTree, KDTree]] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
**kneighbors**(self, X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).
- **return_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

**Returns**

- **neigh_dist** [array, shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True
- **neigh_ind** [array, shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])
```

**kneighbors_graph**(self, X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
**n_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [‘connectivity’, ‘distance’], optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

A [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

*NearestNeighbors.radius_neighbors_graph*

**Examples**

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

**radius_neighbors** *(self, X=None, radius=None, return_distance=True, sort_results=False)*

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

**Parameters**

- **X** [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).
- **return_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.
- **sort_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

New in version 0.22.

**Returns**

- **neigh_dist** [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.
**neigh_ind** [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

**Notes**

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

**Examples**

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** *(self, X=None, radius=None, mode='connectivity', sort_results=False)*

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).
- **mode** [‘connectivity’, ‘distance’], optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.
- **sort_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

**Returns**

- **A** [sparse graph in CSR format, shape = [n_queries, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**set_params**(self,**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

7.30.14 sklearn.neighbors.NeighborhoodComponentsAnalysis

class sklearn.neighbors.NeighborhoodComponentsAnalysis *(n_components=None,
init='auto',
warm_start=False,
max_iter=50, tol=1e-05,
callback=None, verbose=0,
random_state=None)*

Neighborhood Components Analysis

Neighborhood Component Analysis (NCA) is a machine learning algorithm for metric learning. It learns a linear transformation in a supervised fashion to improve the classification accuracy of a stochastic nearest neighbors rule in the transformed space.

Read more in the User Guide.

**Parameters**

**n_components** [int, optional (default=None)] Preferred dimensionality of the projected space.

If None it will be set to n_features.

**init** [string or numpy array, optional (default=’auto’)] Initialization of the linear transformation.

‘auto’ Depending on n_components, the most reasonable initialization will be chosen. If n_components <= n_classes we use ‘lda’, as it uses labels information. If not, but n_components < min(n_features, n_samples), we use ‘pca’, as it projects data in meaningful directions (those of higher variance). Otherwise, we just use ‘identity’.

‘pca’ n_components principal components of the inputs passed to fit will be used to initialize the transformation. (See PCA)

‘lda’ min(n_components, n_classes) most discriminative components of the inputs passed to fit will be used to initialize the transformation. (If n_components > n_classes, the rest of the components will be zero.) (See LinearDiscriminantAnalysis)

‘identity’ If n_components is strictly smaller than the dimensionality of the inputs passed to fit, the identity matrix will be truncated to the first n_components rows.

‘random’ The initial transformation will be a random array of shape (n_components, n_features). Each value is sampled from the standard normal distribution.

numpy array n_features_b must match the dimensionality of the inputs passed to fit and n_features_a must be less than or equal to that. If n_components is not None, n_features_a must match it.

warm_start [bool, optional, (default=False)] If True and fit has been called before, the solution of the previous call to fit is used as the initial linear transformation (n_components and init will be ignored).

max_iter [int, optional (default=50)] Maximum number of iterations in the optimization.

tol [float, optional (default=1e-5)] Convergence tolerance for the optimization.

callback [callable, optional (default=None)] If not None, this function is called after every iteration of the optimizer, taking as arguments the current solution (flattened transformation matrix) and the number of iterations. This might be useful in case one wants to examine or store the transformation found after each iteration.

verbose [int, optional (default=0)] If 0, no progress messages will be printed. If 1, progress messages will be printed to stdout. If > 1, progress messages will be printed and the disp parameter of scipy.optimize.minimize will be set to verbose - 2.

random_state [int or numpy.RandomState or None, optional (default=None)] A pseudo random number generator object or a seed for it if int. If init='random', random_state is used to initialize the random transformation. If init='pca', random_state is passed as an argument to PCA when initializing the transformation.

Attributes

components_ [array, shape (n_components, n_features)] The linear transformation learned during fitting.

n_iter_ [int] Counts the number of iterations performed by the optimizer.

random_state_ [numpy.RandomState] Pseudo random number generator object used during initialization.

Methods

- `fit(self, X, y)` Fit the model according to the given training data.
- `fit_transform(self, X, y=None, **fit_params)` Fit to data, then transform it.
- `get_params(self, deep)` Get parameters for this estimator.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Applies the learned transformation to the given data.

```
__init__(self, n_components=None, init='auto', warm_start=False, max_iter=50, tol=1e-05, callback=None, verbose=0, random_state=None)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Fit the model according to the given training data.

Parameters

X  [array-like, shape (n_samples, n_features)] The training samples.
y  [array-like, shape (n_samples,)] The corresponding training labels.

Returns

self  [object] returns a trained NeighborhoodComponentsAnalysis model.

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X  [numpy array of shape [n_samples, n_features]] Training set.
y  [numpy array of shape [n_samples]] Target values.
**fit_params  [dict] Additional fit parameters.
```
Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

def get_params(self, deep=True)
    Get parameters for this estimator.

    Parameters

    deep [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

    Returns

    params [mapping of string to any] Parameter names mapped to their values.

def set_params(self, **params)
    Set the parameters of this estimator.

    The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
    parameters of the form <component>__<parameter> so that it’s possible to update each component
    of a nested object.

    Parameters

    **params [dict] Estimator parameters.

    Returns

    self [object] Estimator instance.

def transform(self, X)
    Applies the learned transformation to the given data.

    Parameters

    X [array-like, shape (n_samples, n_features)] Data samples.

    Returns

    X_embedded: array, shape (n_samples, n_components) The data samples transformed.

    Raises

    NotFittedError If fit has not been called before.

points in X

neighbors.radius_neighbors_graph(X, radius) Computes the (weighted) graph of Neighbors for points
in X

7.30. sklearn.neighbors: Nearest Neighbors
7.30.15 sklearn.neighbors.kneighbors_graph

sklearn.neighbors.kneighbors_graph(X, n_neighbors, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)

Computes the (weighted) graph of k-Neighbors for points in X.

Read more in the User Guide.

Parameters

- X [array-like of shape (n_samples, n_features) or BallTree] Sample data, in the form of a numpy array or a precomputed BallTree.
- n_neighbors [int] Number of neighbors for each sample.
- mode [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.
- metric [string, default ‘minkowski’] The distance metric used to calculate the k-Neighbors for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the p param equal to 2.)
- p [int, default 2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.
- metric_params [dict, optional] additional keyword arguments for the metric function.
- include_self [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode=’connectivity’ and False for mode=’distance’.
- n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

- A [sparse graph in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight of edge that connects i to j.

### 7.30.16 `sklearn.neighbors.radius_neighbors_graph`

`sklearn.neighbors.radius_neighbors_graph(X, radius, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)`

Computes the (weighted) graph of Neighbors for points in X. Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features) or BallTree] Sample data, in the form of a numpy array or a precomputed BallTree.
- **radius** [float] Radius of neighborhoods.
- **mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.
- **metric** [string, default ‘minkowski’] The distance metric used to calculate the neighbors within a given radius for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the param equal to 2.)
- **p** [int, default 2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.
- **metric_params** [dict, optional] additional keyword arguments for the metric function.
- **include_self** [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode=’connectivity’ and False for mode=’distance’.
- **n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See [Glossary](https://scikit-learn.org/stable/glossary.html) for more details.

**Returns**

- **A** [sparse graph in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight of edge that connects i to j.

7.31.1 `sklearn.neural_network.BernoulliRBM`

class `sklearn.neural_network.BernoulliRBM`(n_components=256, learning_rate=0.1, batch_size=10, n_iter=10, verbose=0, random_state=None)

Bernoulli Restricted Boltzmann Machine (RBM).

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2]. The time complexity of this implementation is $O(d \times 2)$ assuming $d \sim n\text{_features} \sim n\text{_components}$. Read more in the User Guide.

Parameters

- **n_components** [int, default=256] Number of binary hidden units.
- **learning_rate** [float, default=0.1] The learning rate for weight updates. It is highly recommended to tune this hyper-parameter. Reasonable values are in the $10^{[0., -3.]}$ range.
- **batch_size** [int, default=10] Number of examples per minibatch.
- **n_iter** [int, default=10] Number of iterations/sweeps over the training dataset to perform during training.
- **verbose** [int, default=0] The verbosity level. The default, zero, means silent mode.
- **random_state** [integer or RandomState, default=None] A random number generator instance to define the state of the random permutations generator. If an integer is given, it fixes the seed. Defaults to the global numpy random number generator.

Attributes
**intercept_hidden** [array-like, shape (n_components,)] Biases of the hidden units.

**intercept_visible** [array-like, shape (n_features,)] Biases of the visible units.

**components** [array-like, shape (n_components, n_features)] Weight matrix, where n_features in the number of visible units and n_components is the number of hidden units.

**h_samples** [array-like, shape (batch_size, n_components)] Hidden Activation sampled from the model distribution, where batch_size in the number of examples per minibatch and n_components is the number of hidden units.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
```

```python
>>> BernoulliRBM(n_components=2)
```

7.31. sklearn.neural_network: Neural network models
**fit_transform** (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- ****fit_params [dict] Additional fit parameters.

Returns

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (self, deep=True)
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**gibbs** (self, v)
Perform one Gibbs sampling step.

Parameters

- **v** [ndarray of shape (n_samples, n_features)] Values of the visible layer to start from.

Returns

- **v_new** [ndarray of shape (n_samples, n_features)] Values of the visible layer after one Gibbs step.

**partial_fit** (self, X, y=None)
Fit the model to the data X which should contain a partial segment of the data.

Parameters

- **X** [ndarray of shape (n_samples, n_features)] Training data.

Returns

- **self** [BernoulliRBM] The fitted model.

**score_samples** (self, X)
Compute the pseudo-likelihood of X.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Values of the visible layer.
  Must be all-boolean (not checked).

Returns

- **pseudo_likelihood** [ndarray of shape (n_samples,)] Value of the pseudo-likelihood (proxy for likelihood).
Notes

This method is not deterministic: it computes a quantity called the free energy on X, then on a randomly corrupted version of X, and returns the log of the logistic function of the difference.

**set_params**(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

**transform**(self, X)

Compute the hidden layer activation probabilities, \( P(h=1|v=X) \).

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) The data to be transformed.

Returns

h [ndarray of shape (n_samples, n_components)] Latent representations of the data.

Examples using `sklearn.neural_network.BernoulliRBM`

- Restricted Boltzmann Machine features for digit classification

### 7.31.2 `sklearn.neural_network.MLPClassifier`

**class** `sklearn.neural_network.MLPClassifier`(**hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

Parameters

**hidden_layer_sizes** [tuple, length = n_layers - 2, default=(100,)] The ith element represents the number of neurons in the ith hidden layer.
  - ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
  - ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
  - ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
  - ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)

**solver** [‘lbfgs’, ‘sgd’, ‘adam’], default=’adam’] The solver for weight optimization.
  - ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
  - ‘sgd’ refers to stochastic gradient descent.
  - ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch_size** [int, default=’auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, batch_size=min(200, n_samples)

**learning_rate** [‘constant’, ‘invscaling’, ‘adaptive’], default=’constant’] Learning rate schedule for weight updates.
  - ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
  - ‘invscaling’ gradually decreases the learning rate at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)
  - ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver=’sgd’.

**learning_rate_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver=’sgd’ or ‘adam’.

**power_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver=’sgd’.

**max_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, default=True] Whether to shuffle samples in each iteration. Only used when solver=’sgd’ or ‘adam’.

**random_state** [int, RandomState instance or None, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the
random number generator; If None, the random number generator is the RandomState instance used by np.random.

tol [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

verbose [bool, default=False] Whether to print progress messages to stdout.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

momentum [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd'.

nesterovs_momentum [boolean, default=True] Whether to use Nesterov’s momentum. Only used when solver='sgd'.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. The split is stratified, except in a multilabel setting. Only effective when solver='sgd' or 'adam'.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'.

beta_2 [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'.

epsilon [float, default=1e-8] Value for numerical stability in adam. Only used when solver='adam'.

n_iter_no_change [int, default=10] Maximum number of epochs to not meet tol improvement. Only effective when solver='sgd' or 'adam'.

New in version 0.20.

max_fun [int, default=15000] Only used when solver='lbfgs'. Maximum number of loss function calls. The solver iterates until convergence (determined by 'tol'), number of iterations reaches max_iter, or this number of loss function calls. Note that number of loss function calls will be greater than or equal to the number of iterations for the MLPClassifier. New in version 0.22.

Attributes

classes_ [ndarray or list of ndarray of shape (n_classes,)] Class labels for each output.

loss_ [float] The current loss computed with the loss function.

coeefs_ [list, length n_layers - 1] The ith element in the list represents the weight matrix corresponding to layer i.

intercepts_ [list, length n_layers - 1] The ith element in the list represents the bias vector corresponding to layer i + 1.

n_iter_ [int.] The number of iterations the solver has ran.

n_layers_ [int] Number of layers.
n_outputs_ [int] Number of outputs.

out_activation_ [string] Name of the output activation function.

Notes

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to
the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent over-
fitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point
values.

__init__ (self, hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)

Fit the model to data matrix X and target(s) y.

Parameters

X [ndarray or sparse matrix of shape (n_samples, n_features)] The input data.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).
Returns

self  [returns a trained MLP model.]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

property partial_fit
Update the model with a single iteration over the given data.

Parameters

X  [array-like, sparse matrix], shape (n_samples, n_features)] The input data.
y  [array-like, shape (n_samples,)] The target values.
classes  [array, shape (n_classes), default None] Classes across all calls to partial_fit. Can be obtained via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

Returns

self  [returns a trained MLP model.]

predict (self, X)
Predict using the multi-layer perceptron classifier.

Parameters

X  [array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

Returns

y  [ndarray, shape (n_samples,)] or (n_samples, n_classes)] The predicted classes.

predict_log_proba (self, X)
Return the log of probability estimates.

Parameters

X  [ndarray of shape (n_samples, n_features)] The input data.

Returns

log_y_prob  [ndarray of shape (n_samples, n_classes)] The predicted log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_. Equivalent to log(predict_proba(X))

predict_proba (self, X)
Probability estimates.

Parameters

X  [array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

Returns
y_prob [ndarray of shape (n_samples, n_classes)] The predicted probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [object] Estimator instance.

7.31.3 sklearn.neural_network.MLPRegressor

class sklearn.neural_network.MLPRegressor (hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)

Multi-layer Perceptron regressor.
This model optimizes the squared-loss using LBFGS or stochastic gradient descent.
New in version 0.18.

Parameters

**hidden_layer_sizes** [tuple, length = n_layers - 2, default=(100,)] The element represents the number of neurons in the ith hidden layer.

**activation** [{'identity', 'logistic', 'tanh', 'relu'}, default='relu'] Activation function for the hidden layer.

- 'identity', no-op activation, useful to implement linear bottleneck, returns $f(x) = x$
- 'logistic', the logistic sigmoid function, returns $f(x) = 1 / (1 + \exp(-x))$
- 'tanh', the hyperbolic tan function, returns $f(x) = \tanh(x)$
- 'relu', the rectified linear unit function, returns $f(x) = \max(0, x)$

**solver** [{'lbfgs', 'sgd', 'adam'}, default='adam'] The solver for weight optimization.

- 'lbfgs' is an optimizer in the family of quasi-Newton methods.
- 'sgd' refers to stochastic gradient descent.
- 'adam' refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch_size** [int, default='auto'] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to ‘auto’, batch_size=min(200, n_samples)

**learning_rate** [{'constant', 'invscaling', 'adaptive'}, default='constant'] Learning rate schedule for weight updates.

- 'constant' is a constant learning rate given by 'learning_rate_init'.

- 'invscaling' gradually decreases the learning rate learning_rate_ at each time step 't' using an inverse scaling exponent of 'power_t'. effective_learning_rate = learning_rate_init / pow(t, power_t)

- 'adaptive' keeps the learning rate constant to 'learning_rate_init' as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if 'early_stopping' is on, the current learning rate is divided by 5.

Only used when solver='sgd'.

**learning_rate_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver='sgd' or 'adam'.

**power_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to 'invscaling'. Only used when solver='sgd'.

**max_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.
shuffle [bool, default=True] Whether to shuffle samples in each iteration. Only used when
solver='sgd' or 'adam'.

random_state [int, RandomState instance or None, default=None] If int, random_state is the
seed used by the random number generator; If RandomState instance, random_state is the
random number generator; If None, the random number generator is the RandomState in-
stance used by np.random.

tol [float, default=1e-4] Tolerance for the optimization. When the loss or score is not
improving by at least tol for n_iter_no_change consecutive iterations, unless
learning_rate is set to ‘adaptive’, convergence is considered to be reached and training
stops.

verbose [bool, default=False] Whether to print progress messages to stdout.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to
fit as initialization, otherwise, just erase the previous solution. See the Glossary.

momentum [float, default=0.9] Momentum for gradient descent update. Should be between 0
and 1. Only used when solver='sgd'.

nesterovs_momentum [boolean, default=True] Whether to use Nesterov’s momentum. Only
used when solver='sgd' and momentum > 0.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when
validation score is not improving. If set to true, it will automatically set aside 10% of training
data as validation and terminate training when validation score is not improving by at least
tol for n_iter_no_change consecutive epochs. Only effective when solver='sgd' or
‘adam’

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation
set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam,
should be in [0, 1). Only used when solver='adam'

beta_2 [float, default=0.999] Exponential decay rate for estimates of second moment vector in
adam, should be in [0, 1). Only used when solver='adam'

epsilon [float, default=1e-8] Value for numerical stability in adam. Only used when
solver='adam'

n_iter_no_change [int, default=10] Maximum number of epochs to not meet tol improve-
ment. Only effective when solver='sgd' or 'adam'

New in version 0.20.

max_fun [int, default=15000] Only used when solver='lbfgs'. Maximum number of func-
tion calls. The solver iterates until convergence (determined by 'tol'), number of iterations
reaches max_iter, or this number of function calls. Note that number of function calls will
be greater than or equal to the number of iterations for the MLPRegressor.

New in version 0.22.

Attributes

loss_ [float] The current loss computed with the loss function.

coops_ [list, length n_layers - 1] The ith element in the list represents the weight matrix corre-
sponding to layer i.

intercepts_ [list, length n_layers - 1] The ith element in the list represents the bias vector cor-
responding to layer i + 1.
n_iter_  [int] The number of iterations the solver has ran.
n_layers_  [int] Number of layers.
n_outputs_  [int] Number of outputs.
out_activation_  [string] Name of the output activation function.

Notes

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect
to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent over-
fitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y)
Fit the model to data matrix X and target(s) y.

Parameters

X  [ndarray or sparse matrix of shape (n_samples, n_features)] The input data.
y  [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).
Returns

self [returns a trained MLP model.]

```
get_params (self, deep=True)
```
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

```
property partial_fit
```
Update the model with a single iteration over the given data.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.
y [ndarray of shape (n_samples,)] The target values.

Returns

self [returns a trained MLP model.]

```
predict (self, X)
```
Predict using the multi-layer perceptron model.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.

Returns

y [ndarray of shape (n_samples, n_outputs)] The predicted values.

```
score (self, X, y, sample_weight=None)
```
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may
be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples, or (n_samples, n_outputs)] True values for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. $y$. 

---

2384 Chapter 7. API Reference
Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

`set_params` *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.neural_network.MLPRegressor`

- Advanced Plotting With Partial Dependence
- Partial Dependence Plots

7.32 sklearn.pipeline: Pipeline

The `sklearn.pipeline` module implements utilities to build a composite estimator, as a chain of transforms and estimators.

| `pipeline.FeatureUnion(transformer_list[, ...])` | Concatenates results of multiple transformer objects. |
| `pipeline.Pipeline(steps[, memory, verbose])` | Pipeline of transforms with a final estimator. |

7.32.1 sklearn.pipeline.FeatureUnion

class `sklearn.pipeline.FeatureUnion` *(transformer_list, n_jobs=None, transformer_weights=None, verbose=False)*

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a ‘__’. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to ‘drop’.

Read more in the `User Guide`.

New in version 0.13.

Parameters
transformer_list [list of (string, transformer) tuples] List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer.

Changed in version 0.22: Deprecated None as a transformer in favor of ‘drop’.

n_jobs [int or None, optional [default=None]] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

transformer_weights [dict, optional] Multiplicative weights for features per transformer. Keys are transformer names, values the weights.

verbose [boolean, optional[default=False]] If True, the time elapsed while fitting each transformer will be printed as it is completed.

See also:

sklearn.pipeline.make_union Convenience function for simplified feature union construction.

Examples

```python
>>> from sklearn.pipeline import FeatureUnion
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> union = FeatureUnion([('pca', PCA(n_components=1)), ...
                         ('svd', TruncatedSVD(n_components=2))])
>>> X = [[0., 1., 3], [2., 2., 5]]
>>> union.fit_transform(X)
array([[ 1.50104139,  3.00208279,  0.79969274],
       [-1.49895861,  5.70791721, -0.49930726]])
```

Methods

```python
fit(self, X[, y]) Fit all transformers using X.
fit_transform(self, X[, y]) Fit all transformers, transform the data and concatenate results.
get_feature_names(self) Get feature names from all transformers.
get_params(self[, deep]) Get parameters for this estimator.
set_params(self[, **kwargs]) Set the parameters of this estimator.
transform(self, X) Transform X separately by each transformer, concatenate results.
```

__init__ (self, transformer_list, n_jobs=None, transformer_weights=None, verbose=False)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None, **fit_params)
Fit all transformers using X.

Parameters

X [iterable or array-like, depending on transformers] Input data, used to fit transformers.

y [array-like, shape (n_samples, ...), optional] Targets for supervised learning.

Returns

self [FeatureUnion] This estimator
**fit_transform** *(self, X, y=None, **fit_params)*
Fit all transformers, transform the data and concatenate results.

**Parameters**
- **X** [iterable or array-like, depending on transformers] Input data to be transformed.
- **y** [array-like, shape (n_samples, ...), optional] Targets for supervised learning.

**Returns**
- **X_t** [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. `sum_n_components` is the sum of `n_components` (output dimension) over transformers.

**get_feature_names** *(self)*
Get feature names from all transformers.

**Returns**
- **feature_names** [list of strings] Names of the features produced by transform.

**get_params** *(self, deep=True)*
Get parameters for this estimator.

**Parameters**
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(self, **kwargs)*
Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

**Returns**
- **self**

**transform** *(self, X)*
Transform X separately by each transformer, concatenate results.

**Parameters**
- **X** [iterable or array-like, depending on transformers] Input data to be transformed.

**Returns**
- **X_t** [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. `sum_n_components` is the sum of `n_components` (output dimension) over transformers.

**Examples using** **sklearn.pipeline.FeatureUnion**

- Concatenating multiple feature extraction methods
7.32.2 sklearn.pipeline.Pipeline

class sklearn.pipeline.Pipeline(steps, memory=None, verbose=False)

Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be ‘transforms’, that is, they must implement fit and transform methods. The final estimator only needs to implement fit. The transformers in the pipeline can be cached using memory argument.

The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a ‘__’, as in the example below. A step’s estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting it to ‘passthrough’ or None.

Read more in the User Guide.

New in version 0.5.

Parameters

- **steps** [list] List of (name, transform) tuples (implementing fit/transform) that are chained, in the order in which they are chained, with the last object an estimator.
- **memory** [None, str or object with the joblib.Memory interface, optional] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute named_steps or steps to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.
- **verbose** [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

Attributes

- **named_steps** [bunch object, a dictionary with attribute access] Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

sklearn.pipeline.make_pipeline Convenience function for simplified pipeline construction.

Examples

```python
>>> from sklearn import svm
>>> from sklearn.datasets import make_classification
>>> from sklearn.feature_selection import SelectKBest
>>> from sklearn.feature_selection import f_regression
>>> from sklearn.pipeline import Pipeline

# generate some data to play with
>>> X, y = make_classification(... n_informative=5, n_redundant=0, random_state=42)

# ANOVA SVM-C
>>> anova_filter = SelectKBest(f_regression, k=5)
>>> clf = svm.SVC(kernel='linear')
>>> anova_svm = Pipeline([('anova', anova_filter), ('svc', clf)])

# You can set the parameters using the names issued
>>> # For instance, fit using a k of 10 in the SelectKBest
>>> # and a parameter 'C' of the svm
```
>>> anova_svm.set_params(anova__k=10, svc__C=.1).fit(X, y)
Pipeline(steps=[('anova', SelectKBest(...)), ('svc', SVC(...))])
>>> prediction = anova_svm.predict(X)
>>> anova_svm.score(X, y)
0.83
>>> # getting the selected features chosen by anova_filter
>>> anova_svm['anova'].get_support()
array([False, False, True, True, False, False, True, True, False, True, False, False, True, False, False, True, False, True, False, False])
>>> # Another way to get selected features chosen by anova_filter
>>> anova_svm.named_steps.anova.get_support()
array([False, False, True, True, False, False, True, True, False, True, False, False, True, False, False, True, False, True, False, False])
>>> # Indexing can also be used to extract a sub-pipeline.
>>> sub_pipeline = anova_svm[::1]
>>> sub_pipeline
Pipeline(steps=[('anova', SelectKBest(...))])
>>> coef = anova_svm[-1].coef_
>>> anova_svm['svc'] is anova_svm[-1]
True
>>> coef.shape
(1, 10)
>>> sub_pipeline.inverse_transform(coef).shape
(1, 20)

_`__init__`_(self, steps, memory=None, verbose=False)
Initialize self. See help(type(self)) for accurate signature.

decision_function(self, X)
Apply transforms, and decision_function of the final estimator
Parameters

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

**y_score** [array-like of shape (n_samples, n_classes)]

**fit** *(self, X, y=None, **fit_params)*

Fit the model

Fit all the transforms one after the other and transform the data, then fit the transformed data using the final estimator.

Parameters

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params** [dict of string -> object] Parameters passed to the *fit* method of each step, where each parameter name is prefixed such that parameter *p* for step *s* has key *s__p*.

Returns

**self** [Pipeline] This estimator

**fit_predict** *(self, X, y=None, **fit_params)*

Applies *fit_predict* of last step in pipeline after transforms.

Applies *fit_transforms* of a pipeline to the data, followed by the *fit_predict* method of the final estimator in the pipeline. Valid only if the final estimator implements *fit_predict*.

Parameters

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params** [dict of string -> object] Parameters passed to the *fit* method of each step, where each parameter name is prefixed such that parameter *p* for step *s* has key *s__p*.

Returns

**y_pred** [array-like]

**fit_transform** *(self, X, y=None, **fit_params)*

Fit the model and transform with the final estimator

Fits all the transforms one after the other and transforms the data, then uses *fit_transform* on transformed data with the final estimator.

Parameters

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params** [dict of string -> object] Parameters passed to the *fit* method of each step, where each parameter name is prefixed such that parameter *p* for step *s* has key *s__p*.

Returns

**Xt** [array-like of shape (n_samples, n_transformed_features)] Transformed samples
**get_params** (*self*, *deep=True*)
Get parameters for this estimator.

**Parameters**
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**property inverse_transform**
Apply inverse transformations in reverse order
All estimators in the pipeline must support `inverse_transform`.

**Parameters**
- **Xt** [array-like of shape (n_samples, n_transformed_features)] Data samples, where `n_samples` is the number of samples and `n_features` is the number of features. Must fulfill input requirements of last step of pipeline’s `inverse_transform` method.

**Returns**
- **Xt** [array-like of shape (n_samples, n_features)]

**predict** (*self*, *X*, **predict_params**)
Apply transforms to the data, and predict with the final estimator

**Parameters**
- **X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.
- **predict_params** [dict of string -> object] Parameters to the `predict` called at the end of all transformations in the pipeline. Note that while this may be used to return uncertainties from some models with return_std or return_cov, uncertainties that are generated by the transformations in the pipeline are not propagated to the final estimator.

**Returns**
- **y_pred** [array-like]

**predict_log_proba** (*self*, *X*)
Apply transforms, and predict_log_proba of the final estimator

**Parameters**
- **X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**
- **y_score** [array-like of shape (n_samples, n_classes)]

**predict_proba** (*self*, *X*)
Apply transforms, and predict_proba of the final estimator

**Parameters**
- **X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**
- **y_proba** [array-like of shape (n_samples, n_classes)]

**score** (*self*, *X*, *y=None*, *sample_weight=None*)
Apply transforms, and score with the final estimator
Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.

sample_weight [array-like, default=None] If not None, this argument is passed as sample_weight keyword argument to the score method of the final estimator.

Returns

score [float]

score_samples (self, X)
Apply transforms, and score_samples of the final estimator.

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

y_score [ndarray, shape (n_samples,)]

set_params (self, **kwargs)
Set the parameters of this estimator. Valid parameter keys can be listed with get_params().

Returns

self

property transform
Apply transforms, and transform with the final estimator
This also works where final estimator is None: all prior transformations are applied.

Parameters

X [iterable] Data to transform. Must fulfill input requirements of first step of the pipeline.

Returns

Xt [array-like of shape (n_samples, n_transformed_features)]

Examples using sklearn.pipeline.Pipeline

• Sample pipeline for text feature extraction and evaluation

pipeline.make_pipeline(*steps, **kwargs) Construct a Pipeline from the given estimators.
pipeline.make_union(*transformers, **kwargs) Construct a FeatureUnion from the given transformers.

7.32.3 sklearn.pipeline.make_pipeline

sklearn.pipeline.make_pipeline(*steps, **kwargs)
Construct a Pipeline from the given estimators.
This is a shorthand for the Pipeline constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.
Parameters

*steps [list of estimators.]

memory [None, str or object with the joblib.Memory interface, optional] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute named_steps or steps to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

verbose [boolean, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

Returns

p [Pipeline]

See also:

sklearn.pipeline.Pipeline Class for creating a pipeline of transforms with a final estimator.

Examples

```python
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler

Pipeline(steps=[('standardscaler', StandardScaler()),
               ('gaussiannb', GaussianNB())])
```

Examples using sklearn.pipeline.make_pipeline

- Approximate nearest neighbors in TSNE

7.32.4 sklearn.pipeline.make_union

sklearn.pipeline.make_union(*transformers, **kwargs)

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

Parameters

*transformers [list of estimators]

n_jobs [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

Returns

f [FeatureUnion]
scikit-learn user guide, Release 0.22.1

See also:

**`sklearn.pipeline.FeatureUnion`** Class for concatenating the results of multiple transformer objects.

**Examples**

```python
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union

make_union(PCA(), TruncatedSVD())
```

**Examples using `sklearn.pipeline.make_union`**

- Imputing missing values before building an estimator

## 7.33 **sklearn.preprocessing**: Preprocessing and Normalization

The `sklearn.preprocessing` module includes scaling, centering, normalization, binarization methods.

**User guide:** See the [Preprocessing data](#) section for further details.

```python
preprocessing.Binarizer(\[threshold, copy\]) Binarize data (set feature values to 0 or 1) according to a threshold

preprocessing.FunctionTransformer(\[func, . . . \]) Constructs a transformer from an arbitrary callable.

preprocessing.KBinsDiscretizer(\[n_bins, . . . \]) Bin continuous data into intervals.

preprocessing.KernelCenterer() Center a kernel matrix

preprocessing.LabelBinarizer(\[neg_label, . . . \]) Binarize labels in a one-vs-all fashion

preprocessing.LabelEncoder() Encode target labels with value between 0 and `n_classes-1`.

preprocessing.MultiLabelBinarizer(\[classes, . . . \]) Transform between iterable of iterables and a multilabel format

preprocessing.MaxAbsScaler(\[copy\]) Scale each feature by its maximum absolute value.

preprocessing.MinMaxScaler(\[feature_range, copy\]) Transform features by scaling each feature to a given range.

preprocessing.Normalizer(\[norm, copy\]) Normalize samples individually to unit norm.

preprocessing.OneHotEncoder(\[categories, . . . \]) Encode categorical features as a one-hot numeric array.

preprocessing.OrdinalEncoder(\[categories, dtype\]) Encode categorical features as an integer array.

preprocessing.PolynomialFeatures(\[degree, . . . \]) Generate polynomial and interaction features.

preprocessing.PowerTransformer(\[method, . . . \]) Apply a power transform featurewise to make data more Gaussian-like.

preprocessing.QuantileTransformer(\[. . . \]) Transform features using quantiles information.
```

### 7.33.1 sklearn.preprocessing.Binarizer

**class sklearn.preprocessing.Binarizer (threshold=0.0, copy=True)**

Binarize data (set feature values to 0 or 1) according to a threshold

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the User Guide.

**Parameters**

- **threshold** [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

- **copy** [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

**See also:**

- `binarize` Equivalent function without the estimator API.

**Notes**

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

**Examples**

```python
>>> from sklearn.preprocessing import Binarizer
>>> X = [[1., -1., 2.],
      ..., [2., 0., 0.],
      ..., [0., 1., -1.]]
>>> transformer = Binarizer().fit(X)  # fit does nothing.
>>> transformer.transform(X)
array([[1., 0., 1.],
       [1., 0., 0.],
       [0., 1., 0.]])
```
Methods

__init__(self, threshold=0.0, copy=True)
Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

Parameters

X [array-like]

fit_transform (self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default= True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.
transform(self, X, copy=None)

Binarize each element of X

Parameters

X [{array-like, sparse matrix}, shape [n_samples, n_features]] The data to binarize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

copy [bool] Copy the input X or not.

7.33.2 sklearn.preprocessing.FunctionTransformer
class sklearn.preprocessing.FunctionTransformer(func=None, inverse_func=None, validate=False, accept_sparse=False, check_inverse=True, kw_args=None, inv_kw_args=None)

Constructs a transformer from an arbitrary callable.

A FunctionTransformer forwards its X (and optionally y) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

New in version 0.17.

Read more in the User Guide.

Parameters

func [callable, optional default=None] The callable to use for the transformation. This will be passed the same arguments as transform, with args and kwargs forwarded. If func is None, then func will be the identity function.

inverse_func [callable, optional default=None] The callable to use for the inverse transformation. This will be passed the same arguments as inverse transform, with args and kwargs forwarded. If inverse_func is None, then inverse_func will be the identity function.

validate [bool, optional default=False] Indicate that the input X array should be checked before calling func. The possibilities are:

• If False, there is no input validation.
• If True, then X will be converted to a 2-dimensional NumPy array or sparse matrix. If the conversion is not possible an exception is raised.

Changed in version 0.22: The default of validate changed from True to False.

accept_sparse [boolean, optional] Indicate that func accepts a sparse matrix as input. If validate is False, this has no effect. Otherwise, if accept_sparse is False, sparse matrix inputs will cause an exception to be raised.

check_inverse [bool, default=True] Whether to check that or func followed by inverse_func leads to the original inputs. It can be used for a sanity check, raising a warning when the condition is not fulfilled.

New in version 0.20.

kw_args [dict, optional] Dictionary of additional keyword arguments to pass to func.

inv_kw_args [dict, optional] Dictionary of additional keyword arguments to pass to inverse_func.
Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import FunctionTransformer
>>> transformer = FunctionTransformer(np.log1p)
>>> X = np.array([[0, 1], [2, 3]])
>>> transformer.transform(X)
array([[0.        , 0.69314718],
       [1.09861229, 1.38629436]])
```

Methods

- **fit**
  - `fit(self, X[, y])`
    - Fit transformer by checking X.

- **fit_transform**
  - `fit_transform(self, X[, y])`
    - Fit to data, then transform it.

- **get_params**
  - `get_params(self[, deep])`
    - Get parameters for this estimator.

- **inverse_transform**
  - `inverse_transform(self, X)`
    - Transform X using the inverse function.

- **set_params**
  - `set_params(self, **params)`
    - Set the parameters of this estimator.

- **transform**
  - `transform(self, X)`
    - Transform X using the forward function.

```python
def __init__(self, func=None, inverse_func=None, validate=False, accept_sparse=False, check_inverse=True, kw_args=None, inv_kw_args=None):
    Initialize self. See help(type(self)) for accurate signature.

def fit(self, X[, y])
    Fit transformer by checking X.
    
    Parameters
    X [array-like, shape (n_samples, n_features)] Input array.

    Returns
    self

def fit_transform(self, X[, y])
    Fit to data, then transform it.
    
    Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

    Parameters
    X [numpy array of shape [n_samples, n_features]] Training set.
    y [numpy array of shape [n_samples]] Target values.

    Returns
    X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(self, deep=True)
    Get parameters for this estimator.

    Parameters
    deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
```

Returns

\textbf{params}  [mapping of string to any] Parameter names mapped to their values.

\textbf{inverse\_transform}(\textit{self}, \textit{X})
Transform \textit{X} using the inverse function.

Parameters

\textbf{X}  [array-like, shape (n\_samples, n\_features)] Input array.

Returns

\textbf{X\_out}  [array-like, shape (n\_samples, n\_features)] Transformed input.

\textbf{set\_params}(\textit{self}, **\textit{params})
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form \texttt{\textit{<component>\_\textit{<parameter>}}} so that it's possible to update each component
of a nested object.

Parameters

**\textit{params}  [dict] Estimator parameters.

Returns

\textbf{self}  [object] Estimator instance.

\textbf{transform}(\textit{self}, \textit{X})
Transform \textit{X} using the forward function.

Parameters

\textbf{X}  [array-like, shape (n\_samples, n\_features)] Input array.

Returns

\textbf{X\_out}  [array-like, shape (n\_samples, n\_features)] Transformed input.

\textbf{Examples using} \texttt{sklearn.preprocessing.FunctionTransformer}

• Using \texttt{FunctionTransformer} to select columns

7.33.3 \texttt{sklearn.preprocessing.KBinsDiscretizer}

\textbf{class} \texttt{sklearn.preprocessing.KBinsDiscretizer}(\textit{n\_bins}=5, \textit{encode}='onehot', \textit{strategy}='quantile')

Bin continuous data into intervals.

Read more in the \textit{User Guide}.

Parameters

\textbf{n\_bins}  [int or array-like, shape (n\_features,) (default=5)] The number of bins to produce.
 Raises \texttt{ValueError} if \textit{n\_bins} < 2.

\textbf{encode}  [{'onehot', 'onehot-dense', 'ordinal'}, (default='onehot')] Method used to encode the transformed result.

\textbf{onehot} Encode the transformed result with one-hot encoding and return a sparse matrix.
 Ignored features are always stacked to the right.
**onehot-dense**  Encode the transformed result with one-hot encoding and return a dense array. Ignored features are always stacked to the right.

**ordinal**  Return the bin identifier encoded as an integer value.

**strategy**  \[\{'uniform', 'quantile', 'kmeans'\}, (default='quantile')\] Strategy used to define the widths of the bins.

**uniform**  All bins in each feature have identical widths.

**quantile**  All bins in each feature have the same number of points.

**kmeans**  Values in each bin have the same nearest center of a 1D k-means cluster.

**Attributes**

- **n_bins_**  [int array, shape (n_features,)] Number of bins per feature. Bins whose width are too small (i.e., <= 1e-8) are removed with a warning.

- **bin_edges_**  [array of arrays, shape (n_features,)] The edges of each bin. Contain arrays of varying shapes (n_bins_, ) Ignored features will have empty arrays.

**See also:**

- **sklearn.preprocessing.Binarizer**  Class used to bin values as 0 or 1 based on a parameter threshold.

**Notes**

In bin edges for feature i, the first and last values are used only for inverse_transform. During transform, bin edges are extended to:

\[
\text{np.concatenate([-np.inf, bin_edges[i][1:-1], np.inf])}
\]

You can combine KBinsDiscretizer with sklearn.compose.ColumnTransformer if you only want to preprocess part of the features.

KBinsDiscretizer might produce constant features (e.g., when encode = 'onehot' and certain bins do not contain any data). These features can be removed with feature selection algorithms (e.g., sklearn.feature_selection.VarianceThreshold).

**Examples**

```python
>>> X = [[-2, 1, -4, -1],
...      [-1, 2, -3, -0.5],
...      [ 0, 3, -2, 0.5],
...      [ 1, 4, -1, 2]]
>>> est = KBinsDiscretizer(n_bins=3, encode='ordinal', strategy='uniform')
>>> est.fit(X)
KBinsDiscretizer(...)  # doctest: +SKIP
>>> Xt = est.transform(X)
>>> Xt
array([[ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.],
        [ 0., 0., 0., 0.]])
```
Sometimes it may be useful to convert the data back into the original feature space. The inverse_transform function converts the binned data into the original feature space. Each value will be equal to the mean of the two bin edges.

```python
>>> est.bin_edges_[0]
array([[-2., -1., 0., 1.])

>>> est.inverse_transform(Xt)
array([[[-1.5, 1.5, -3.5, -0.5],
       [-0.5, 2.5, -2.5, -0.5],
       [ 0.5, 3.5, -1.5, 0.5],
       [ 0.5, 3.5, -1.5, 1.5]])
```

### Methods

- **fit**(self, X[, y]) Fit the estimator.
- **fit_transform**(self, X[, y]) Fit to data, then transform it.
- **get_params**(self[, deep]) Get parameters for this estimator.
- **inverse_transform**(self, Xt) Transform discretized data back to original feature space.
- **set_params**(self, **params) Set the parameters of this estimator.
- **transform**(self, X) Discretize the data.

**__init__**(self, n_bins=5, encode='onehot', strategy='quantile')

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y=None)

Fit the estimator.

**Parameters**

- **X** [numeric array-like, shape (n_samples, n_features)] Data to be discretized.
- **y** [None] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

**Returns**

self

**fit_transform**(self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params**(self, deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean] If True, will return the parameters for this estimator and contained subobjects that are estimators.
**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** *(self, Xt)*

Transform discretized data back to original feature space.

Note that this function does not regenerate the original data due to discretization rounding.

**Parameters**

- **Xt** [numeric array-like, shape (n_sample, n_features)] Transformed data in the binned space.

**Returns**

- **Xinv** [numeric array-like] Data in the original feature space.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*

Discretize the data.

**Parameters**

- **X** [numeric array-like, shape (n_samples, n_features)] Data to be discretized.

**Returns**

- **Xt** [numeric array-like or sparse matrix] Data in the binned space.

---

**Examples using sklearn.preprocessing.KBinsDiscretizer**

- *Using KBinsDiscretizer to discretize continuous features*
- *Demonstrating the different strategies of KBinsDiscretizer*

---

**7.33.4 sklearn.preprocessing.KernelCenterer**

**class sklearn.preprocessing.KernelCenterer**

Center a kernel matrix

Let K(x, z) be a kernel defined by phi(x)^T phi(z), where phi is a function mapping x to a Hilbert space. KernelCenterer centers (i.e., normalize to have zero mean) the data without explicitly computing phi(x). It is equivalent to centering phi(x) with sklearn.preprocessing.StandardScaler(with_std=False).

Read more in the *User Guide*. 

---
Attributes

- **K_fit_rows_** [array, shape (n_samples,)] Average of each column of kernel matrix
- **K_fit_all_** [float] Average of kernel matrix

Examples

```python
>>> from sklearn.preprocessing import KernelCenterer
>>> from sklearn.metrics.pairwise import pairwise_kernels

>>> X = [[ 1., -2., 2.],
...      [-2., 1., 3.],
...      [ 4., 1., -2.]]

>>> K = pairwise_kernels(X, metric='linear')

>>> K
array([[ 9.,  2., -2.],
        [ 2., 14., -13.],
        [-2., -13., 21.]])

>>> transformer = KernelCenterer().fit(K)

>>> transformer
KernelCenterer()

>>> transformer.transform(K)
array([[ 5.,  0., -5.],
        [ 0., 14., -14.],
        [-5., -14., 19.]])
```

</tr>
</tbody>
</table>

__init__(self)

Initialize self. See help(type(self)) for accurate signature.

**fit (self, K, y=None)**

Fit KernelCenterer

**Parameters**

- **K** [numpy array of shape [n_samples, n_samples]] Kernel matrix.

**Returns**

- **self** [returns an instance of self.]

**fit_transform (self, X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
**fit_params** [dict] Additional fit parameters.

**get_params** (self, deep=True)
Get parameters for this estimator.

Parameters

    deep [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

Returns

    params [mapping of string to any] Parameter names mapped to their values.

**set_params** (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

    **params [dict] Estimator parameters.

Returns

    self [object] Estimator instance.

**transform** (self, K, copy=True)
Center kernel matrix.

Parameters

    K [numpy array of shape [n_samples1, n_samples2]] Kernel matrix.

    copy [boolean, optional, default True] Set to False to perform inplace computation.

Returns

    K_new [numpy array of shape [n_samples1, n_samples2]]

7.33.5 sklearn.preprocessing.LabelBinarizer

**class** sklearn.preprocessing.LabelBinarizer (neg_label=0,
    pos_label=1,
    sparse_output=False)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend
these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one
needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer
makes this process easy with the transform method.

At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. La-
belBinarizer makes this easy with the inverse_transform method.

Read more in the User Guide.

Parameters
neg_label [int (default: 0)] Value with which negative labels must be encoded.

pos_label [int (default: 1)] Value with which positive labels must be encoded.

sparse_output [boolean (default: False)] True if the returned array from transform is desired to be in sparse CSR format.

Attributes

classes_ [array of shape [n_class]] Holds the label for each class.

y_type_ [str] Represents the type of the target data as evaluated by utils.multiclass.type_of_target. Possible type are 'continuous', 'continuous-multioutput', 'binary', 'multiclass', 'multiclass-multioutput', 'multilabel-indicator', and 'unknown'.

sparse_input_ [boolean] True if the input data to transform is given as a sparse matrix, False otherwise.

See also:

label_binarize function to perform the transform operation of LabelBinarizer with fixed classes.

sklearn.preprocessing.OneHotEncoder encode categorical features using a one-hot aka one-of-K scheme.

Examples

```python
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 6, 4, 2])
LabelBinarizer()
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
      [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```python
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
array([[1],
      [0],
      [0],
      [1]])
```

Passing a 2D matrix for multilabel classification

```python
>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer()
>>> lb.classes_
array([0, 1, 2])
>>> lb.transform([0, 1, 2, 1])
array([[1, 0, 0],
      [0, 1, 0],
      [0, 0, 1],
      [0, 1, 0]])
```
Methods

</tbody>
</table>

**__init__**(self, neg_label=0, pos_label=1, sparse_output=False)
Initialize self. See help(type(self)) for accurate signature.

**fit**(self, y)
Fit label binarizer

**Parameters**

- **y** [array of shape [n_samples,] or [n_samples, n_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification.

**Returns**

- **self** [returns an instance of self.]

**fit_transform**(self, y)
Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

**Parameters**

- **y** [array or sparse matrix of shape [n_samples,] or [n_samples, n_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

**Returns**

- **Y** [array or CSR matrix of shape [n_samples, n_classes]] Shape will be [n_samples, 1] for binary problems.

**get_params**(self, deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform**(self, Y, threshold=None)
Transform binary labels back to multi-class labels

**Parameters**

- **Y** [numpy array or sparse matrix with shape [n_samples, n_classes]] Target values. All sparse matrices are converted to CSR before inverse transformation.
**threshold** [float or None] Threshold used in the binary and multi-label cases.

Use 0 when $Y$ contains the output of decision_function (classifier). Use 0.5 when $Y$ contains the output of predict_proba.

If None, the threshold is assumed to be half way between neg_label and pos_label.

**Returns**

$y$ [numpy array or CSR matrix of shape [n_samples] Target values.]

**Notes**

In the case when the binary labels are fractional (probabilistic), inverse_transform chooses the class with the greatest value. Typically, this allows to use the output of a linear model’s decision_function method directly as the input of inverse_transform.

**set_params**(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**transform**(self, $y$)

Transform multi-class labels to binary labels

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

**Parameters**

$y$ [array or sparse matrix of shape [n_samples,] or [n_samples, n_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

**Returns**

$Y$ [numpy array or CSR matrix of shape [n_samples, n_classes]] Shape will be [n_samples, 1] for binary problems.

### 7.33.6 sklearn.preprocessing.LabelEncoder

**class** sklearn.preprocessing.LabelEncoder

Encode target labels with value between 0 and n_classes-1.

This transformer should be used to encode target values, *i.e.* $y$, and not the input $X$.

Read more in the *User Guide.*

New in version 0.12.

**Attributes**

classes_ [array of shape (n_class,)] Holds the label for each class.
See also:

**sklearn.preprocessing.OrdinalEncoder** Encode categorical features using an ordinal encoding scheme.

**sklearn.preprocessing.OneHotEncoder** Encode categorical features as a one-hot numeric array.

**Examples**

`LabelEncoder` can be used to normalize labels.

```python
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2])
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.

```python
>>> le = preprocessing.LabelEncoder()
>>> le.fit(['paris', 'paris', 'tokyo', 'amsterdam'])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(['tokyo', 'tokyo', 'paris'])
array([2, 2, 1])
>>> list(le.inverse_transform([2, 2, 1])
['tokyo', 'tokyo', 'paris']
```

**Methods**

- `fit(self, y)` Fit label encoder
- `fit_transform(self, y)` Fit label encoder and return encoded labels
- `get_params(self[, deep])` Get parameters for this estimator.
- `inverse_transform(self, y)` Transform labels back to original encoding.
- `set_params(self[, **params])` Set the parameters of this estimator.
- `transform(self, y)` Transform labels to normalized encoding.

```python
__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

fit(self, y)
Fit label encoder

Parameters
- y [array-like of shape (n_samples,)] Target values.

Returns
```
self [returns an instance of self.]

fit_transform (self, y)
Fit label encoder and return encoded labels

Parameters

y [array-like of shape [n_samples]] Target values.

Returns

y [array-like of shape [n_samples]]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, y)
Transform labels back to original encoding.

Parameters

y [numpy array of shape [n_samples]] Target values.

Returns

y [numpy array of shape [n_samples]]

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, y)
Transform labels to normalized encoding.

Parameters

y [array-like of shape [n_samples]] Target values.

Returns

y [array-like of shape [n_samples]]
Transform between iterable of iterables and a multilabel format

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

Parameters

- **classes** [array-like of shape [n_classes] (optional)] Indicates an ordering for the class labels. All entries should be unique (cannot contain duplicate classes).

- **sparse_output** [boolean (default: False)] Set to true if output binary array is desired in CSR sparse format

Attributes

- **classes_** [array of labels] A copy of the classes parameter where provided, or otherwise, the sorted set of classes found when fitting.

See also:

- **sklearn.preprocessing.OneHotEncoder** encode categorical features using a one-hot aka one-of-K scheme.

Examples

```python
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[1, 1, 0],
       [0, 0, 1]])
>>> mlb.classes_
array([1, 2, 3])
```

A common mistake is to pass in a list, which leads to the following issue:

```python
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit([['sci-fi', 'thriller', 'comedy']])
MultiLabelBinarizer()
>>> mlb.classes_
array(['-', 'c', 'd', 'e', 'f', 'h', 'i', 'l', 'm', 'o', 'r', 's', 't', 'y'], dtype=object)
```

To correct this, the list of labels should be passed in as:

```python
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit([['sci-fi', 'thriller', 'comedy']])
MultiLabelBinarizer()
```
>>> mlb.classes_
array(['comedy', 'sci-fi', 'thriller'], dtype=object)

</tbody>
</table>

__init__(self, classes=None, sparse_output=False)  
Initialize self. See help(type(self)) for accurate signature.

```python
fit (self, y)
Fit the label sets binarizer, storing `classes_`

Parameters

y  [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
If the `classes` parameter is set, `y` will not be iterated.

Returns

self  [returns this MultiLabelBinarizer instance]
```

```python
fit_transform (self, y)
Fit the label sets binarizer and transform the given label sets

Parameters

y  [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
If the `classes` parameter is set, `y` will not be iterated.

Returns

y_indicator  [array or CSR matrix, shape (n_samples, n_classes)] A matrix such that
`y_indicator[i, j] = 1` iff `classes_[j]` is in `y[i]`, and 0 otherwise.
```

```python
get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.
```

```python
inverse_transform (self, yt)
Transform the given indicator matrix into label sets

Parameters
```
yt [array or sparse matrix of shape (n_samples, n_classes)] A matrix containing only 1s and 0s.

Returns

y [list of tuples] The set of labels for each sample such that y[i] consists of classes_[j] for each yt[i, j] == 1.

set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(self, y)
Transform the given label sets

Parameters

y [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
If the classes parameter is set, y will not be iterated.

Returns

y_indicator [array or CSR matrix, shape (n_samples, n_classes)] A matrix such that y_indicator[i, j] = 1 iff classes_[j] is in y[i], and 0 otherwise.

7.33.8 sklearn.preprocessing.MaxAbsScaler

class sklearn.preprocessing.MaxAbsScaler(copy=True)
Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.

This scaler can also be applied to sparse CSR or CSC matrices.

New in version 0.17.

Parameters

copy [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

Attributes

scale_ [ndarray, shape (n_features,)] Per feature relative scaling of the data.
New in version 0.17: scale_ attribute.

max_abs_ [ndarray, shape (n_features,)] Per feature maximum absolute value.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across partial_fit calls.

See also:
maxabs_scale

Equivalent function without the estimator API.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import MaxAbsScaler
>>> X = [[ 1., -1., 2.],
...      [ 2., 0., 0.],
...      [ 0., 1., -1.]]
>>> transformer = MaxAbsScaler().fit(X)
>>> transformer
MaxAbsScaler()
>>> transformer.transform(X)
array([[ 0.5, -1.,  1.],
       [ 1.,  0.,  0.],
       [ 0.,  1., -0.5]])
```

__init__(self, copy=True)

Initialize self. See help(type(self)) for accurate signature.

fit (self, X[, y])

Compute the maximum absolute value to be used for later scaling.

Parameters

- **X** ([array-like, sparse matrix], shape [n_samples, n_features]) The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

fit_transform (self, X[, y])

Fit to data, then transform it.

Parameters

- **X** ([array-like, sparse matrix], shape [n_samples, n_features]) Training set.
y [numpy array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)

Scale back the data to the original representation

Parameters

X [[array-like, sparse matrix]] The data that should be transformed back.

partial_fit (self, X, y=None)

Online computation of max absolute value of X for later scaling.

All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

Parameters

X [[array-like, sparse matrix], shape [n_samples, n_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

y [None] Ignored.

Returns

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)

Scale the data

Parameters

X [[array-like, sparse matrix]] The data that should be scaled.
Examples using `sklearn.preprocessing.MaxAbsScaler`

- Compare the effect of different scalers on data with outliers

### 7.33.9 sklearn.preprocessing.MinMaxScaler

```python
class sklearn.preprocessing.MinMaxScaler(feature_range=(0, 1), copy=True)
```

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, e.g. between zero and one.

The transformation is given by:

\[
X_{\text{std}} = \frac{X - \text{X.min}(axis=0)}{\text{X.max}(axis=0) - \text{X.min}(axis=0)}
\]

\[
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]

where \(\text{min}, \text{max} = \text{feature_range}\).

The transformation is calculated as:

\[
X_{\text{scaled}} = \text{scale} \times X + \text{min} - X_{\text{min}}(axis=0) \times \text{scale}
\]

\[
\text{where } \text{scale} = \frac{\text{max} - \text{min}}{\text{X.max}(axis=0) - \text{X.min}(axis=0)}
\]

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the [User Guide](#).

**Parameters**

- `feature_range` ([tuple (min, max), default=(0, 1)] Desired range of transformed data.
- `copy` [bool, default=True] Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).

**Attributes**

- `min_` [ndarray of shape (n_features,)] Per feature adjustment for minimum. Equivalent to \(\text{min} - X_{\text{min}}(axis=0) \times \text{self.scale}_{-}\)
- `scale_` [ndarray of shape (n_features,)] Per feature relative scaling of the data. Equivalent to \((\text{max} - \text{min}) / (\text{X.max}(axis=0) - \text{X.min}(axis=0))\)
  
  New in version 0.17: `scale_` attribute.
- `data_min_` [ndarray of shape (n_features,)] Per feature minimum seen in the data
  
  New in version 0.17: `data_min_`
- `data_max_` [ndarray of shape (n_features,)] Per feature maximum seen in the data
  
  New in version 0.17: `data_max_`
- `data_range_` [ndarray of shape (n_features,)] Per feature range \((\text{data_max}_{-} - \text{data_min}_{-})\) seen in the data
  
  New in version 0.17: `data_range_`
- `n_samples_seen_` [int] The number of samples processed by the estimator. It will be reset on new calls to fit, but increments across `partial_fit` calls.

See also:
**minmax_scale** Equivalent function without the estimator API.

**Notes**

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformes, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**Examples**

```python
>>> from sklearn.preprocessing import MinMaxScaler
>>> data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
>>> scaler = MinMaxScaler()
>>> print(scaler.fit(data))
MinMaxScaler()
>>> print(scaler.data_max_)
[ 1. 18.]
>>> print(scaler.transform(data))
[[0. 0.]
 [0.25 0.25]
 [0.5 0.5]
 [1. 1.]]
>>> print(scaler.transform([[2, 2]]))
[[1.5 0.]]
```

**Methods**

- `fit(self, X[, y])` Compute the minimum and maximum to be used for later scaling.
- `fit_transform(self, X[, y])` Fit to data, then transform it.
- `get_params(self[, deep])` Get parameters for this estimator.
- `inverse_transform(self, X)` Undo the scaling of X according to feature_range.
- `partial_fit(self, X[, y])` Online computation of min and max on X for later scaling.
- `set_params(self, **params)` Set the parameters of this estimator.
- `transform(self, X)` Scale features of X according to feature_range.

```python
__init__(self, feature_range=(0, 1), copy=True)
Initialize self. See help(type(self)) for accurate signature.
```

**fit**(self, X, y=None)
Compute the minimum and maximum to be used for later scaling.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.
- **y** [None] Ignored.

**Returns**

- **self** [object] Fitted scaler.
fit_transform (self, X, y=None, **fit_params)
    Fit to data, then transform it.

    Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

    Parameters
    X [numpy array of shape [n_samples, n_features]] Training set.
    y [numpy array of shape [n_samples]] Target values.
    **fit_params [dict] Additional fit parameters.

    Returns
    X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)
    Get parameters for this estimator.

    Parameters
    deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns
    params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)
    Undo the scaling of X according to feature_range.

    Parameters
    X [array-like of shape (n_samples, n_features)] Input data that will be transformed. It cannot be sparse.

    Returns
    Xt [array-like of shape (n_samples, n_features)] Transformed data.

partial_fit (self, X, y=None)
    Online computation of min and max on X for later scaling.

    All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

    Parameters
    X [array-like of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.
    y [None] Ignored.

    Returns

set_params (self, **params)
    Set the parameters of this estimator.

    The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

    Parameters
    **params [dict] Estimator parameters.
Returns

self [object] Estimator instance.

transform (self, X)
Scale features of X according to feature_range.

Parameters

X [array-like of shape (n_samples, n_features)] Input data that will be transformed.

Returns

Xt [array-like of shape (n_samples, n_features)] Transformed data.

Examples using sklearn.preprocessing.MinMaxScaler

- Univariate Feature Selection
- Compare Stochastic learning strategies for MLPClassifier
- Compare the effect of different scalers on data with outliers

7.33.10 sklearn.preprocessing.Normalizer

class sklearn.preprocessing.Normalizer (norm='l2', copy=True)

Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1 or l2) equals one.

This transformer is able to work both with dense numpy arrays and scipy.sparse matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the User Guide.

Parameters

norm ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample.

copy [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

normalize Equivalent function without the estimator API.

Notes

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.
Examples

```python
>>> from sklearn.preprocessing import Normalizer
>>> X = [[4, 1, 2, 2],
...      [1, 3, 9, 3],
...      [5, 7, 5, 1]]
>>> transformer = Normalizer().fit(X)  # fit does nothing.
>>> transformer
Normalizer()
>>> transformer.transform(X)
array([[0.8, 0.2, 0.4, 0.4],
       [0.1, 0.3, 0.9, 0.3],
       [0.5, 0.7, 0.5, 0.1]])
```

</tbody>
</table>

```python
__init__(self, norm='l2', copy=True)
Initialize self. See help(type(self)) for accurate signature.

fit(self, X, y=None)
Do nothing and return the estimator unchanged
This method is just there to implement the usual API and hence work in pipelines.

Parameters
X [array-like]

fit_transform(self, X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns
X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters
dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
```
**set_params** *(self, **params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

  **params** [dict] Estimator parameters.

**Returns**

  self [object] Estimator instance.

**transform** *(self, X, copy=None)*
Scale each non zero row of X to unit norm

**Parameters**

  X [[array-like, sparse matrix], shape [n_samples, n_features]] The data to normalize, row by row. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

  copy [bool, optional (default: None)] Copy the input X or not.

---

**7.33.11 sklearn.preprocessing.OneHotEncoder**

**class** sklearn.preprocessing.OneHotEncoder *(categories='auto', drop=None, sparse=True, dtype=<class 'numpy.float64'>, handle_unknown='error')*

Encode categorical features as a one-hot numeric array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are encoded using a one-hot (aka ‘one-of-K’ or ‘dummy’) encoding scheme. This creates a binary column for each category and returns a sparse matrix or dense array (depending on the sparse parameter)

By default, the encoder derives the categories based on the unique values in each feature. Alternatively, you can also specify the categories manually.

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Note: a one-hot encoding of y labels should use a LabelBinarizer instead.

Read more in the *User Guide*.

Changed in version 0.20.

**Parameters**

  categories ['auto' or a list of array-like, default='auto'] Categories (unique values) per feature:
  • ‘auto’ : Determine categories automatically from the training data.
• list: categories[i] holds the categories expected in the ith column. The passed categories should not mix strings and numeric values within a single feature, and should be sorted in case of numeric values.

The used categories can be found in the categories_ attribute.

drop ['first' or a array-like of shape (n_features,)., default=None] Specifies a methodology to use to drop one of the categories per feature. This is useful in situations where perfectly collinear features cause problems, such as when feeding the resulting data into a neural network or an unregularized regression.

• None : retain all features (the default).
• ‘first’ : drop the first category in each feature. If only one category is present, the feature will be dropped entirely.
• array : drop[i] is the category in feature X[:, i] that should be dropped.

sparse [bool, default=True] Will return sparse matrix if set True else will return an array.

dtype [number type, default=np.float] Desired dtype of output.

handle_unknown [{‘error’, ‘ignore’}, default=’error’] Whether to raise an error or ignore if an unknown categorical feature is present during transform (default is to raise). When this parameter is set to ‘ignore’ and an unknown category is encountered during transform, the resulting one-hot encoded columns for this feature will be all zeros. In the inverse transform, an unknown category will be denoted as None.

Attributes

categories_ [list of arrays] The categories of each feature determined during fitting (in order of the features in X and corresponding with the output of transform). This includes the category specified in drop (if any).

drop_idx_ [array of shape (n_features,)] drop_idx_[i] is the index in categories_[i] of the category to be dropped for each feature. None if all the transformed features will be retained.

See also:

sklearn.preprocessing.OrdinalEncoder Performs an ordinal (integer) encoding of the categorical features.

sklearn.feature_extraction.DictVectorizer Performs a one-hot encoding of dictionary items (also handles string-valued features).

sklearn.feature_extraction.FeatureHasher Performs an approximate one-hot encoding of dictionary items or strings.

sklearn.preprocessing.LabelBinarizer Binarizes labels in a one-vs-all fashion.

sklearn.preprocessing.MultiLabelBinarizer Transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to a binary one-hot encoding.
>>> from sklearn.preprocessing import OneHotEncoder
>>> enc = OneHotEncoder(handle_unknown='ignore')
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
OneHotEncoder(handle_unknown='ignore')
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([['Female', 1], ['Male', 4]]).toarray()
array([[1., 0., 1., 0., 0.],
       [0., 1., 0., 0., 0.]])
>>> enc.inverse_transform([[None, 2]], dtype=object)
array([['Male', 1],
       ['Female', 3]], dtype=object)
>>> enc.get_feature_names(['gender', 'group'])
array(['gender_Female', 'gender_Male', 'group_1', 'group_2', 'group_3'],
      dtype=object)
>>> drop_enc = OneHotEncoder(drop='first').fit(X)
>>> drop_enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> drop_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 0., 0.],
       [1., 1., 0.]])

Methods

fit(self, X[, y]) Fit OneHotEncoder to X.

fit_transform(self, X[, y]) Fit OneHotEncoder to X, then transform X.

get_feature_names(self[, input_features]) Return feature names for output features.

get_params(self[, deep]) Get parameters for this estimator.

inverse_transform(self, X) Convert the data back to the original representation.

set_params(self, **params) Set the parameters of this estimator.

transform(self, X) Transform X using one-hot encoding.

__init__(self, categories='auto', drop=None, sparse=True, dtype=<class 'numpy.float64'>, handle_unknown='error') Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None) Fit OneHotEncoder to X.

Parameters

X [array-like, shape [n_samples, n_features]] The data to determine the categories of each feature.

y [None] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

self

fit_transform (self, X, y=None) Fit OneHotEncoder to X, then transform X.

Equivalent to fit(X).transform(X) but more convenient.

Parameters
X [array-like, shape [n_samples, n_features]] The data to encode.

y [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

Returns

X_out [sparse matrix if sparse=True else a 2-d array] Transformed input.

`get_feature_names` (self, input_features=None)

Return feature names for output features.

Parameters

input_features [list of str of shape (n_features,)] String names for input features if available.
By default, “x0”, “x1”, . . . “xn_features” is used.

Returns

output_feature_names [ndarray of shape (n_output_features,)] Array of feature names.

`get_params` (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

`inverse_transform` (self, X)

Convert the data back to the original representation.

In case unknown categories are encountered (all zeros in the one-hot encoding), None is used to represent this category.

Parameters

X [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed data.

Returns

X_tr [array-like, shape [n_samples, n_features]] Inverse transformed array.

`set_params` (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

`transform` (self, X)

Transform X using one-hot encoding.

Parameters
X [array-like, shape [n_samples, n_features]] The data to encode.

Returns

X_out [sparse matrix if sparse=True else a 2-d array] Transformed input.

Examples using sklearn.preprocessing.OneHotEncoder

- Feature transformations with ensembles of trees
- Permutation Importance vs Random Forest Feature Importance (MDI)
- Column Transformer with Mixed Types

7.33.12 sklearn.preprocessing.OrdinalEncoder

class sklearn.preprocessing.OrdinalEncoder (categories='auto',
                                           dtype='numpy.float64')

Encode categorical features as an integer array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are converted to ordinal integers. This results in a single column of integers (0 to n_categories - 1) per feature.

Read more in the User Guide.

Changed in version 0.20.1.

Parameters

categories ['auto' or a list of array-like, default='auto'] Categories (unique values) per feature:
  • 'auto' : Determine categories automatically from the training data.
  • list : categories[i] holds the categories expected in the ith column. The passed categories should not mix strings and numeric values, and should be sorted in case of numeric values.

The used categories can be found in the categories_ attribute.

dtype [number type, default np.float64] Desired dtype of output.

Attributes

categories_ [list of arrays] The categories of each feature determined during fitting (in order of the features in X and corresponding with the output of transform).

See also:

sklearn.preprocessing.OneHotEncoder Performs a one-hot encoding of categorical features.

sklearn.preprocessing.LabelEncoder Encodes target labels with values between 0 and n_classes-1.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to an ordinal encoding.
```python
>>> from sklearn.preprocessing import OrdinalEncoder
>>> enc = OrdinalEncoder()
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
OrdinalEncoder()
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([[0, 1], [2]])
array([[0., 2.],
       [1., 0.]])
>>> enc.inverse_transform([[1, 0], [0, 1]])
array([[['Male', 1], ['Female', 2]], dtype=object])
```

**Methods**

- **fit**
  ```python
  fit(self, X[, y])
  Fit the OrdinalEncoder to X.
  ```
  - **Parameters**
    - **X** [array-like, shape [n_samples, n_features]] The data to determine the categories of each feature.
    - **y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.
  - **Returns**
    - **self**

- **fit_transform**
  ```python
  fit_transform(self, X[, y])
  Fit to data, then transform it.
  ```
  - **Parameters**
    - **X** [numpy array of shape [n_samples, n_features]] Training set.
    - **y** [numpy array of shape [n_samples]] Target values.
    - ****fit_params** [dict] Additional fit parameters.
  - **Returns**
    - **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

- **__init__**
  ```python
  __init__(self, categories='auto', dtype=<class 'numpy.float64'>)
  Initialize self. See help(type(self)) for accurate signature.
  ```

- **inverse_transform**
  ```python
  inverse_transform(self, X)
  Convert the data back to the original representation.
  ```

- **set_params**
  ```python
  set_params(self,**params)
  Set the parameters of this estimator.
  ```

- **transform**
  ```python
  transform(self, X)
  Transform X to ordinal codes.
  ```
get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)
Convert the data back to the original representation.

Parameters

X [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed
data.

Returns

X_tr [array-like, shape [n_samples, n_features]] Inverse transformed array.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Transform X to ordinal codes.

Parameters

X [array-like, shape [n_samples, n_features]] The data to encode.

Returns

X_out [sparse matrix or a 2-d array] Transformed input.

7.33.13 sklearn.preprocessing.PolynomialFeatures

class sklearn.preprocessing.PolynomialFeatures (degree=2, interaction_only=False, include_bias=True, order='C')

Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than
or equal to the specified degree. For example, if an input sample is two dimensional and of the form [a, b], the
degree-2 polynomial features are [1, a, b, a^2, ab, b^2].

Parameters

**interaction_only**  [boolean, default = False] If true, only interaction features are produced: features that are products of at most degree distinct input features (so not \(x[1] \times 2, x[0] \times x[2] \times 3\), etc.).

**include_bias**  [boolean] If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).

**order**  [str in {'C', 'F'}, default ‘C’] Order of output array in the dense case. ‘F’ order is faster to compute, but may slow down subsequent estimators.

New in version 0.21.

**Attributes**

**powers_**  [array, shape (n_output_features, n_input_features)] powers_[i, j] is the exponent of the jth input in the ith output.

**n_input_features_**  [int] The total number of input features.

**n_output_features_**  [int] The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

**Notes**

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See examples/linear_model/plot_polynomial_interpolation.py

**Examples**

```python
>>> import numpy as np
>>> from sklearn.preprocessing import PolynomialFeatures
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[ 1., 0., 1., 0., 0., 1.],
       [ 1., 2., 3., 4., 6., 9.],
       [ 1., 4., 5., 16., 20., 25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[ 1., 0., 1., 0.],
       [ 1., 2., 3., 6.],
       [ 1., 4., 5., 20.]])
```

**Methods**

- `fit(self, X[, y])`  Compute number of output features.
- `fit_transform(self, X[, y])`  Fit to data, then transform it.
- `get_feature_names(self[, input_features])`  Return feature names for output features
Table 276 – continued from previous page

<table>

__init__ (self, degree=2, interaction_only=False, include_bias=True, order='C')

Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)

Compute number of output features.

Parameters

X [array-like, shape (n_samples, n_features)] The data.

Returns

self [instance]

fit_transform (self, X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_feature_names (self, input_features=None)

Return feature names for output features

Parameters

input_features [list of string, length n_features, optional] String names for input features if available. By default, “x0”, “x1”, … “xn_features” is used.

Returns

output_feature_names [list of string, length n_output_features]

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (self, X)
Transform data to polynomial features

Parameters

X [array-like or CSR/CSC sparse matrix, shape [n_samples, n_features]] The data to transform, row by row.

Prefer CSR over CSC for sparse input (for speed), but CSC is required if the degree is 4 or higher. If the degree is less than 4 and the input format is CSC, it will be converted to CSR, have its polynomial features generated, then converted back to CSC.

If the degree is 2 or 3, the method described in “Leveraging Sparsity to Speed Up Polynomial Feature Expansions of CSR Matrices Using K-Simplex Numbers” by Andrew Nystrom and John Hughes is used, which is much faster than the method used on CSC input. For this reason, a CSC input will be converted to CSR, and the output will be converted back to CSC prior to being returned, hence the preference of CSR.

Returns

XP [np.ndarray or CSR/CSC sparse matrix, shape [n_samples, NP]] The matrix of features, where NP is the number of polynomial features generated from the combination of inputs.

Examples using sklearn.preprocessing.PolynomialFeatures

- Polynomial interpolation
- Robust linear estimator fitting
- Underfitting vs. Overfitting

7.33.14 sklearn.preprocessing.PowerTransformer

class sklearn.preprocessing.PowerTransformer (method='yeo-johnson', standardize=True, copy=True)

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, PowerTransformer supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the User Guide.

New in version 0.20.

Parameters

method [str, (default='yeo-johnson')] The power transform method. Available methods are:
- ‘yeo-johnson’ [Rf3e1504535de-1], works with positive and negative values
- ‘box-cox’ [Rf3e1504535de-2], only works with strictly positive values

**standardize** [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

**copy** [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

**Attributes**

- **lambdas_** [array of float, shape (n_features,)] The parameters of the power transformation for the selected features.

**See also:**

- **power_transform** Equivalent function without the estimator API.
- **QuantileTransformer** Maps data to a standard normal distribution with the parameter `output_distribution='normal'`.

**Notes**

NaNs are treated as missing values: disregarded in `fit`, and maintained in `transform`.

For a comparison of the different scalers, transformers, and normalizers, see `example/preprocessing/plot_all_scaling.py`.

**References**

[Rf3e1504535de-1], [Rf3e1504535de-2]

**Examples**

```python
>>> import numpy as np
>>> from sklearn.preprocessing import PowerTransformer
>>> pt = PowerTransformer()
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(pt.fit(data))
PowerTransformer()
>>> print(pt.lambdas_)
[ 1.386... -3.100...]
>>> print(pt.transform(data))
[[-1.316... -0.707...]
 [ 0.209... -0.707...]
 [ 1.106... 1.414...]]
```

**Methods**

- **fit** (self, X[, y]) Estimate the optimal parameter lambda for each feature.
- **fit_transform** (self, X[, y]) Fit to data, then transform it.

`__init__`(self, method='yeo-johnson', standardize=True, copy=True)
Initialize self. See help(type(self)) for accurate signature.

`fit`(self, X, y=None)
Estimate the optimal parameter lambda for each feature.

The optimal lambda parameter for minimizing skewness is estimated on each feature independently using maximum likelihood.

Parameters

X [array-like, shape (n_samples, n_features)] The data used to estimate the optimal transformation parameters.

y [Ignored]

Returns

self [object]

`fit_transform`(self, X, y=None)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

`get_params`(self, deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

`inverse_transform`(self, X)
Apply the inverse power transformation using the fitted lambdas.

The inverse of the Box-Cox transformation is given by:

7.33. sklearn.preprocessing: Preprocessing and Normalization 2431
The inverse of the Yeo-Johnson transformation is given by:

```python
if X >= 0 and lambda_ == 0:
    X = exp(X_trans) - 1
elif X >= 0 and lambda_ != 0:
    X = (X_trans * lambda_ + 1) ** (1 / lambda_) - 1
elif X < 0 and lambda_ != 2:
    X = 1 - (-(2 - lambda_) * X_trans + 1) ** (1 / (2 - lambda_))
elif X < 0 and lambda_ == 2:
    X = 1 - exp(-X_trans)
```

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] The transformed data.

**Returns**

- `X` [array-like, shape (n_samples, n_features)] The original data

**set_params**(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- `**params` [dict] Estimator parameters.

**Returns**

**transform**(self, X)

Apply the power transform to each feature using the fitted lambdas.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] The data to be transformed using a power transformation.

**Returns**

- `X_trans` [array-like, shape (n_samples, n_features)] The transformed data.

**Examples using sklearn.preprocessing.PowerTransformer**

- Map data to a normal distribution
- Compare the effect of different scalers on data with outliers
Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the User Guide.

New in version 0.19.

Parameters

- **n_quantiles** [int, optional (default=1000 or n_samples)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n_quantiles is larger than the number of samples, n_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.

- **output_distribution** [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.

- **ignore_implicit_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

- **subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

- **copy** [boolean, optional, (default=True)] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

Attributes

- **n_quantiles_** [integer] The actual number of quantiles used to discretize the cumulative distribution function.

- **quantiles_** [ndarray, shape (n_quantiles, n_features)] The values corresponding the quantiles of reference.

- **references_** [ndarray, shape(n_quantiles, )] Quantiles of references.
See also:

**quantile_transform**  Equivalent function without the estimator API.

**PowerTransformer**  Perform mapping to a normal distribution using a power transform.

**StandardScaler**  Perform standardization that is faster, but less robust to outliers.

**RobustScaler**  Perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

Examples

```python
generate code block from scikit-learn user guide, Release 0.22.1
```

```
```
**fit_transform** *(self, X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(self, deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** *(self, X)*

Back-projection to the original space.

**Parameters**

- **X** [ndarray or sparse matrix, shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse *csc_matrix*. Additionally, the sparse matrix needs to be nonnegative if *ignore_implicit_zeros* is False.

**Returns**

- **Xt** [ndarray or sparse matrix, shape (n_samples, n_features)] The projected data.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**transform** *(self, X)*

Feature-wise transformation of the data.

**Parameters**

- **X** [ndarray or sparse matrix, shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse *csc_matrix*. Additionally, the sparse matrix needs to be nonnegative if *ignore_implicit_zeros* is False.
Returns

\[ X_t \quad [\text{ndarray or sparse matrix, shape (n_samples, n_features)}] \] The projected data.

Examples using `sklearn.preprocessing.QuantileTransformer`

- Partial Dependence Plots
- Effect of transforming the targets in regression model
- Map data to a normal distribution
- Compare the effect of different scalers on data with outliers

7.33.16 `sklearn.preprocessing.RobustScaler`

class `sklearn.preprocessing.RobustScaler`(*with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True*)

Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the `transform` method.

Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.

New in version 0.17.

Read more in the `User Guide`.

Parameters

- `with_centering` [boolean, True by default] If True, center the data before scaling. This will cause `transform` to raise an exception when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

- `with_scaling` [boolean, True by default] If True, scale the data to interquartile range.

- `quantile_range` [tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0] Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate `scale_`.

  New in version 0.18.

- `copy` [boolean, optional, default is True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

Attributes

- `center_` [array of floats] The median value for each feature in the training set.

- `scale_` [array of floats] The (scaled) interquartile range for each feature in the training set.

  New in version 0.17: `scale_` attribute.

See also:
**robust_scale** Equivalent function without the estimator API.

**sklearn.decomposition.PCA** Further removes the linear correlation across features with ‘whiten=True’.

**Notes**

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**Examples**

```python
>>> from sklearn.preprocessing import RobustScaler
>>> X = [[ 1., -2., 2.],
...      [ -2., 1., 3.],
...      [ 4., 1., -2.]]
>>> transformer = RobustScaler().fit(X)
>>> transformer.transform(X)
array([[ 0., -2., 0.],
       [-1., 0., 0.4],
       [ 1., 0., -1.6]])
```

**Methods**

- `fit(self, X[, y])` Compute the median and quantiles to be used for scaling.
- `fit_transform(self, X[, y], **fit_params)` Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.
- `get_params(self[, deep])` Get parameters for this estimator.
- `inverse_transform(self, X)` Scale back the data to the original representation.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(self, X)` Center and scale the data.

```python
__init__ (self, with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True)
Initialize self. See help(type(self)) for accurate signature.
```

```python
fit (self, X, y=None)
    Compute the median and quantiles to be used for scaling.

    Parameters
    X [array-like, shape [n_samples, n_features]] The data used to compute the median and quantiles used for later scaling along the features axis.
```

```python
fit_transform (self, X, y=None, **fit_params)
    Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

    Parameters
    X [numpy array of shape [n_samples, n_features]] Training set.
```
y  [numpy array of shape [n_samples]] Target values.

**fit_params  [dict] Additional fit parameters.

Returns

X_new  [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (self, deep=True)

Get parameters for this estimator.

Parameters

depth  [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

inverse_transform (self, X)

Scale back the data to the original representation

Parameters

X  [array-like] The data used to scale along the specified axis.

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form `<component>__<parameter>` so that it's possible to update each component
of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [object] Estimator instance.

transform (self, X)

Center and scale the data.

Parameters

X  [array-like, sparse matrix]] The data used to scale along the specified axis.

Examples using sklearn.preprocessing.RobustScaler

- Compare the effect of different scalers on data with outliers

7.33.17 sklearn.preprocessing.StandardScaler

class sklearn.preprocessing.StandardScaler (copy=True, with_mean=True, with_std=True)

Standardize features by removing the mean and scaling to unit variance

The standard score of a sample $x$ is calculated as:

$$z = \frac{x - u}{s}$$
where \( \mu \) is the mean of the training samples or zero if \( \text{with\_mean}=\text{False} \), and \( \sigma \) is the standard deviation of the training samples or one if \( \text{with\_std}=\text{False} \).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Mean and standard deviation are then stored to be used on later data using \text{transform}.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave badly if the individual features do not more or less look like standard normally distributed data (e.g. Gaussian with 0 mean and unit variance).

For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger than others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing \( \text{with\_mean}=\text{False} \) to avoid breaking the sparsity structure of the data.

Read more in the \textit{User Guide}.

\textbf{Parameters}

- \texttt{copy} [boolean, optional, default True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.
- \texttt{with\_mean} [boolean, True by default] If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.
- \texttt{with\_std} [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

\textbf{Attributes}

- \texttt{scale\_} [ndarray or None, shape (n\_features,)] Per feature relative scaling of the data. This is calculated using \texttt{np.sqrt(var\_)}. Equal to None when \texttt{with\_std}=\text{False}.
- \texttt{mean\_} [ndarray or None, shape (n\_features,)] The mean value for each feature in the training set. Equal to None when \texttt{with\_mean}=\text{False}.
- \texttt{var\_} [ndarray or None, shape (n\_features,)] The variance for each feature in the training set. Used to compute \texttt{scale\_}. Equal to None when \texttt{with\_std}=\text{False}.
- \texttt{n\_samples\_seen\_} [int or array, shape (n\_features,)] The number of samples processed by the estimator for each feature. If there are not missing samples, the \texttt{n\_samples\_seen} will be an integer, otherwise it will be an array. Will be reset on new calls to fit, but increments across \texttt{partial\_fit} calls.

\textbf{See also:}

- \texttt{scale} Equivalent function without the estimator API.
- \texttt{sklearn.decomposition.PCA} Further removes the linear correlation across features with \texttt{whiten=True}.
Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

We use a biased estimator for the standard deviation, equivalent to \texttt{numpy.std(x, ddof=0)}. Note that the choice of \texttt{ddof} is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see \texttt{examples/preprocessing/plot_all_scaling.py}.

Examples

```python
>>> from sklearn.preprocessing import StandardScaler
>>> data = [[0, 0], [0, 0], [1, 1], [1, 1]]
>>> scaler = StandardScaler()
>>> print(scaler.fit(data))
StandardScaler()
>>> print(scaler.mean_)
[0.5 0.5]
>>> print(scaler.transform(data))
[[ 1.  1.]
 [ 1.  1.]
 [ 1.  1.]]
>>> print(scaler.transform([[2, 2]]))
[[3. 3.]]
```

Methods

```python
fit(self, X[, y])
    Compute the mean and std to be used for later scaling.

fit_transform(self, X[, y])
    Fit to data, then transform it.

get_params(self[, deep])
    Get parameters for this estimator.

inverse_transform(self, X[, copy])
    Scale back the data to the original representation

partial_fit(self, X[, y])
    Online computation of mean and std on X for later scaling.

set_params(self, \*\*params)
    Set the parameters of this estimator.

transform(self, X[, copy])
    Perform standardization by centering and scaling
```

__init__(self, copy=True, with_mean=True, with_std=True)
    Initialize self. See help(type(self)) for accurate signature.

fit (self, X, y=None)
    Compute the mean and std to be used for later scaling.

Parameters

- **X** ([array-like, sparse matrix], shape [n_samples, n_features]) The data used to compute the mean and standard deviation used for later scaling along the features axis.
- **y** Ignored

fit_transform (self, X, y=None, **fit_params)
    Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

-X [numpy array of shape [n_samples, n_features]] Training set.
-y [numpy array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

**Returns**

-X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(self, deep=**True)**

Get parameters for this estimator.

**Parameters**

depth [bool, default=**True**] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** *(self, X, copy=None)*

Scale back the data to the original representation.

**Parameters**

-X [array-like, shape [n_samples, n_features]] The data used to scale along the features axis.

*copy* [bool, optional (default: None)] Copy the input X or not.

**Returns**

-X_tr [array-like, shape [n_samples, n_features]] Transformed array.

**partial_fit** *(self, X, y=None)*

Online computation of mean and std on X for later scaling.

All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque. “Algorithms for computing the sample variance: Analysis and recommendations.” The American Statistician 37.3 (1983): 242-247:

**Parameters**

-X [[array-like, sparse matrix], shape [n_samples, n_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

-y [None] Ignored.

**Returns**

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**
**params**  [dict]  Estimator parameters.

Returns

**self**  [object]  Estimator instance.

**transform**(self, X, copy=None)
Perform standardization by centering and scaling

Parameters

**X**  [array-like, shape [n_samples, n_features]]  The data used to scale along the features axis.

**copy**  [bool, optional (default: None)]  Copy the input X or not.

### 7.33.18 sklearn.preprocessing.add_dummy_feature

**sklearn.preprocessing.add_dummy_feature** (*X, value=1.0*)

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

**Parameters**

- **X** {array-like, sparse matrix}, shape [n_samples, n_features] Data.
- **value** [float] Value to use for the dummy feature.

**Returns**

- **X** {array, sparse matrix}, shape [n_samples, n_features + 1] Same data with dummy feature added as first column.

**Examples**

```python
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[1., 0., 1.],
       [1., 1., 0.]])
```

### 7.33.19 sklearn.preprocessing.binarize

**sklearn.preprocessing.binarize** (*X, threshold=0.0, copy=True*)

Boolean thresholding of array-like or scipy.sparse matrix

Read more in the *User Guide*.

**Parameters**

- **X** {array-like, sparse matrix}, shape [n_samples, n_features] The data to binarize, element by element. scipy.sparse matrices should be in CSR or CSC format to avoid an un-necessary copy.
- **threshold** [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.
- **copy** [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR / CSC matrix and if axis is 1).

See also:
**Binarizer** Performs binarization using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

### 7.33.20 `sklearn.preprocessing.label_binarize`

`sklearn.preprocessing.label_binarize(y, classes, neg_label=0, pos_label=1, sparse_output=False)`

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme. This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

**Parameters**

- `y` [array-like] Sequence of integer labels or multilabel data to encode.
- `classes` [array-like of shape [n_classes]] Uniquely holds the label for each class.
- `neg_label` [int (default: 0)] Value with which negative labels must be encoded.
- `pos_label` [int (default: 1)] Value with which positive labels must be encoded.
- `sparse_output` [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

**Returns**

- `Y` [numpy array or CSR matrix of shape [n_samples, n_classes]] Shape will be [n_samples, 1] for binary problems.

**See also:**

`LabelBinarizer` class used to wrap the functionality of label_binarize and allow for fitting to classes independently of the transform operation

**Examples**

```python
>>> from sklearn.preprocessing import label_binarize
>>> label_binarize([1, 6], classes=[1, 2, 4, 6])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

The class ordering is preserved:

```python
>>> label_binarize([1, 6], classes=[1, 6, 4, 2])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```python
>>> label_binarize(['yes', 'no', 'no', 'yes'], classes=['no', 'yes'])
array([[0],
       [0],
       [0],
       [1]])
```
Examples using `sklearn.preprocessing.label_binarize`

- Receiver Operating Characteristic (ROC)
- Precision-Recall

### 7.33.21 sklearn.preprocessing.maxabs_scale

`sklearn.preprocessing.maxabs_scale(X, axis=0, copy=True)`

Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] The data.
- `axis` [int (0 by default)] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
- `copy` [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

**See also:**

- `MaxAbsScaler` Performs scaling to the [-1, 1] range using the ‘Transformer’ API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**Notes**

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

### 7.33.22 sklearn.preprocessing.minmax_scale

`sklearn.preprocessing.minmax_scale(X, feature_range=(0, 1), axis=0, copy=True)`

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by (when `axis=0`):

\[
X_{scaled} = \frac{X - \text{min}(axis=0)}{\text{max}(axis=0) - \text{min}(axis=0)} \times (\text{max} - \text{min}) + \text{min}
\]

where min, max = feature_range.

The transformation is calculated as (when `axis=0`):

\[
X_{scaled} = \text{scale} \times X + \text{min} - \text{min}(axis=0) \times \text{scale}
\]

where scale = (max - min) / (max(axis=0) - min(axis=0))
This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the User Guide.

New in version 0.17: minmax_scale function interface to sklearn.preprocessing.MinMaxScaler.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The data.
- **feature_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.
- **axis** [int, default=0] Axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
- **copy** [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

See also:

**MinMaxScaler** Performs scaling to a given range using the‘‘Transformer‘‘ API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples using sklearn.preprocessing.minmax_scale

- Compare the effect of different scalers on data with outliers

7.33.23 sklearn.preprocessing.normalize

sklearn.preprocessing.normalize(X, norm='l2', axis=1, copy=True, return_norm=False)

Scale input vectors individually to unit norm (vector length).

Read more in the User Guide.

Parameters

- **X** [[array-like, sparse matrix], shape [n_samples, n_features]] The data to normalize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.
- **norm** ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non-zero sample (or each non-zero feature if axis is 0).
- **axis** [0 or 1, optional (1 by default)] axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.
- **copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).
- **return_norm** [boolean, default False] whether to return the computed norms

Returns

- **X** [[array-like, sparse matrix], shape [n_samples, n_features]] Normalized input X.
norms [array, shape [n_samples] if axis=1 else [n_features]] An array of norms along given axis for X. When X is sparse, a NotImplementedError will be raised for norm ‘l1’ or ‘l2’.

See also:

Normalizer Performs normalization using the Transformer API (e.g. an part of a preprocessing sklearn.pipeline.Pipeline).

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

7.33.24 sklearn.preprocessing.quantile_transform

sklearn.preprocessing.quantile_transform(X, axis=0, n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy='warn')

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the User Guide.

Parameters

X [array-like, sparse matrix] The data to transform.

axis [int, (default=0)] Axis used to compute the means and standard deviations along. If 0, transform each feature, otherwise (if 1) transform each sample.

n_quantiles [int, optional (default=1000 or n_samples)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n_quantiles is larger than the number of samples, n_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.

output_distribution [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are ‘uniform’ (default) or ‘normal’.

ignore_implicit_zeros [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

subsample [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.
random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

copy [boolean, optional, (default="warn")]] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array). If True, a copy of X is transformed, leaving the original X unchanged.

Deprecated since version 0.21: The default value of parameter copy will be changed from False to True in 0.23. The current default of False is being changed to make it more consistent with the default copy values of other functions in sklearn.preprocessing. Furthermore, the current default of False may have unexpected side effects by modifying the value of X inplace.

Returns

Xt [ndarray or sparse matrix, shape (n_samples, n_features)] The transformed data.

See also:

QuantileTransformer Performs quantile-based scaling using the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

power_transform Maps data to a normal distribution using a power transformation.

scale Performs standardization that is faster, but less robust to outliers.

robust_scale Performs robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=rng, copy=True)
array([...])
```

Examples using sklearn.preprocessing.quantile_transform

- Effect of transforming the targets in regression model
7.33.25 sklearn.preprocessing.robust_scale

sklearn.preprocessing.robust_scale(X, axis=0, with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True)

Standardize a dataset along any axis
Center to the median and component wise scale according to the interquartile range.

Read more in the User Guide.

Parameters

X [array-like] The data to center and scale.
axis [int (0 by default)] axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
with_centering [boolean, True by default] If True, center the data before scaling.
with_scaling [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).
quantile_range [tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0] Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate scale_. New in version 0.18.
copy [boolean, optional, default is True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

See also:

RobustScaler Performs centering and scaling using the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_centering=False (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

7.33.26 sklearn.preprocessing.scale

sklearn.preprocessing.scale(X, axis=0, with_mean=True, with_std=True, copy=True)

Standardize a dataset along any axis
Center to the mean and component wise scale to unit variance.

Read more in the User Guide.

Parameters

X [array-like] The data to center and scale.
axis [int (0 by default)] axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
with_mean [boolean, True by default] If True, center the data before scaling.
with_std [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).
copy [boolean, optional, default is True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

See also:

RobustScaler Performs centering and scaling using the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_centering=False (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.
X [{array-like, sparse matrix}] The data to center and scale.

axis [int (0 by default)] axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.

with_mean [boolean, True by default] If True, center the data before scaling.

with_std [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

copy [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

See also:

StandardScaler Performs scaling to unit variance using the'’Transformer’’ API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_mean=False (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

We use a biased estimator for the standard deviation, equivalent to numpy.std(x, ddof=0). Note that the choice of ddof is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples using sklearn.preprocessing.scale

• A demo of K-Means clustering on the handwritten digits data

7.33.27 sklearn.preprocessing.power_transform

sklearn.preprocessing.power_transform (X, method='warn', standardize=True, copy=True)

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, power_transform supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the User Guide.
Parameters

X  [array-like, shape (n_samples, n_features)] The data to be transformed using a power transformation.

method  [str] The power transform method. Available methods are:
  • ‘yeo-johnson’ [1], works with positive and negative values
  • ‘box-cox’ [2], only works with strictly positive values

The default method will be changed from ‘box-cox’ to ‘yeo-johnson’ in version 0.23. To suppress the FutureWarning, explicitly set the parameter.

standardize  [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

copy  [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

Returns

X_trans  [array-like, shape (n_samples, n_features)] The transformed data.

See also:

PowerTransformer  Equivalent transformation with the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

quantile_transform  Maps data to a standard normal distribution with the parameter output_distribution='normal'.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

7.34 sklearn.random_projection: Random projection

Random Projection transformers

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the Johnson-Lindenstrauss lemma (quoting Wikipedia):

In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

User guide: See the Random Projection section for further details.

7.34.1 sklearn.random_projection.GaussianRandomProjection

class sklearn.random_projection.GaussianRandomProjection(n_components='auto', eps=0.1, random_state=None)

Reduce dimensionality through Gaussian random projection

The components of the random matrix are drawn from N(0, 1 / n_components).

Read more in the User Guide.

New in version 0.13.

Parameters

n_components [int or ‘auto’, optional (default = ‘auto’)] Dimensionality of the target projection space.

n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the eps parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

eps [strictly positive float, optional (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’.

Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.
**random_state** [int, RandomState instance or None, optional (default=None)] Control the pseudo random number generator used to generate the matrix at fit time. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Attributes**

- **n_components_** [int] Concrete number of components computed when `n_components='auto'`.
- **components_** [numpy array of shape [n_components, n_features]] Random matrix used for the projection.

**See also:**

`SparseRandomProjection`

**Examples**

```python
>>> import numpy as np
>>> from sklearn.random_projection import GaussianRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = GaussianRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
```

**__init__**(self, n_components='auto', eps=0.1, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

**fit**(self, X, y=None)

Generate a sparse random projection matrix

**Parameters**

- **X** [numpy array or scipy.sparse of shape [n_samples, n_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.
- **y** Ignored

**Returns**

- **self**  

**fit_transform**(self, X, y=None, **fit_params)

Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(self, X)
Project the data by using matrix product with the random matrix.

Parameters

X [numpy array or scipy.sparse of shape [n_samples, n_features]] The input data to project into a smaller dimensional space.

Returns

X_new [numpy array or scipy sparse of shape [n_samples, n_components]] Projected array.

7.34.2 sklearn.random_projection.SparseRandomProjection

class sklearn.random_projection.SparseRandomProjection(n_components='auto', density='auto', eps=0.1, dense_output=False, random_state=None)

Reduce dimensionality through sparse random projection

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note $s = 1 / \text{density}$ the components of the random matrix are drawn from:
- \sqrt{s} / \sqrt{n_{\text{components}}} \) with probability \( \frac{1}{2s} \)
- 0 with probability 1 - \( \frac{1}{s} \)
- +\sqrt{s} / \sqrt{n_{\text{components}}} \) with probability \( \frac{1}{2s} \)

Read more in the User Guide.

New in version 0.13.

Parameters

- **n_components** [int or ‘auto’, optional (default = ‘auto’)] Dimensionality of the target projection space.

  n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the eps parameter.

  It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

- **density** [float in range [0, 1], optional (default='auto')] Ratio of non-zero component in the random projection matrix.

  If density = ‘auto’, the value is set to the minimum density as recommended by Ping Li et al.: 1 / \sqrt{n_{\text{features}}}.

  Use density = 1 / 3.0 if you want to reproduce the results from Achlioptas, 2001.

- **eps** [strictly positive float, optional, (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’.

  Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

- **dense_output** [boolean, optional (default=False)] If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse. In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.

  If False, the projected data uses a sparse representation if the input is sparse.

- **random_state** [int, RandomState instance or None, optional (default=None)] Control the pseudo random number generator used to generate the matrix at fit time. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- **n_components_** [int] Concrete number of components computed when n_components=’auto’.

- **components_** [CSR matrix with shape [n_components, n_features]] Random matrix used for the projection.

- **density_** [float in range 0.0 - 1.0] Concrete density computed from when density = “auto”.

Examples

```python
>>> import numpy as np
>>> from sklearn.random_projection import SparseRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = SparseRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
>>> # very few components are non-zero
>>> np.mean(transformer.components_ != 0)
0.0100...
```

Methods

```python
__init__(self, n_components='auto', density='auto', eps=0.1, dense_output=False, random_state=None)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit(self, X[, y])
```

Generate a sparse random projection matrix

</tr>
</thead>
<tbody>
<tr>
<td><strong>y</strong></td>
</tr>
</tbody>
</table>
**fit_params**  [dict] Additional fit parameters.

Returns

**X_new**  [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params  (**self, deep=True**)  Get parameters for this estimator.

Parameters

**deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params**  [mapping of string to any] Parameter names mapped to their values.

set_params  (**self, **params**)  Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params**  [dict] Estimator parameters.

Returns

**self**  [object] Estimator instance.

transform  (**self, X**)  Project the data by using matrix product with the random matrix

Parameters

**X**  [numpy array or scipy.sparse of shape [n_samples, n_features]] The input data to project into a smaller dimensional space.

Returns

**X_new**  [numpy array or scipy sparse of shape [n_samples, n_components]] Projected array.

Examples using `sklearn.random_projection.SparseRandomProjection`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…*

`sklearn.random_projection.johnson_lindenstrauss_min_dim(...)`  Find a ‘safe’ number of components to randomly project to

7.34.3 `sklearn.random_projection.johnson_lindenstrauss_min_dim`

`sklearn.random_projection.johnson_lindenstrauss_min_dim(n_samples, eps=0.1)`  Find a ‘safe’ number of components to randomly project to

The distortion introduced by a random projection $p$ only changes the distance between two points by a factor $(1 + \varepsilon)$ in an euclidean space with good probability. The projection $p$ is an eps-embedding as defined by:
(1 - \(\epsilon\)) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \epsilon) \|u - v\|^2

Where \(u\) and \(v\) are any rows taken from a dataset of shape \([n_{samples}, n_{features}]\), \(\epsilon\) is in \([0, 1]\) and \(p\) is a projection by a random Gaussian \(N(0, 1)\) matrix with shape \([n_{components}, n_{features}]\) (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the \(\epsilon\)-embedding is given by:

\[n_{components} \geq 4 \log(n_{samples}) / (\epsilon^2 / 2 - \epsilon^3 / 3)\]

Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an \(\epsilon\)-embedding.

Read more in the User Guide.

Parameters

- **n_samples** [int or numpy array of int greater than 0,] Number of samples. If an array is given, it will compute a safe number of components array-wise.
- **\(\epsilon\)** [float or numpy array of float in \([0, 1]\), optional (default=0.1)] Maximum distortion rate as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

Returns

- **n_components** [int or numpy array of int,] The minimal number of components to guarantee with good probability an \(\epsilon\)-embedding with \(n_{samples}\).

7.35 `sklearn.semi_supervised` Semi-Supervised Learning

The `sklearn.semi_supervised` module implements semi-supervised learning algorithms. These algorithms utilized small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

**User guide:** See the Semi-Supervised section for further details.
Label Propagation classifier

```
semi_supervised.LabelPropagation((kernel, ...))
```

LabelSpreading model for semi-supervised learning

```
semi_supervised.LabelSpreading((kernel, ...))
```

## 7.35.1 `sklearn.semi_supervised.LabelPropagation`

The `LabelPropagation` class is the Label Propagation classifier. Read more in the User Guide.

### Parameters

- **kernel** ([`'knn'`, `'rbf'`, callable]) String identifier for kernel function to use or the kernel function itself. Only `'rbf'` and `'knn'` strings are valid inputs. The function passed should take two inputs, each of shape [n_samples, n_features], and return a [n_samples, n_samples] shaped weight matrix.
- **gamma** ([float]) Parameter for rbf kernel
- **n_neighbors** ([integer > 0]) Parameter for knn kernel
- **max_iter** ([integer]) Change maximum number of iterations allowed
- **tol** ([float]) Convergence tolerance: threshold to consider the system at steady state
- **n_jobs** ([int or None, optional (default=None)]) The number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See Glossary for more details.

### Attributes

- **X_** ([array, shape = [n_samples, n_features]]) Input array.
- **classes_** ([array, shape = [n_classes]]) The distinct labels used in classifying instances.
- **label_distributions_** ([array, shape = [n_samples, n_classes]]) Categorical distribution for each item.
- **transduction_** ([array, shape = [n_samples]]) Label assigned to each item via the transduction.
- **n_iter_** ([int]) Number of iterations run.

### See also:

- **LabelSpreading** Alternate label propagation strategy more robust to noise

Examples

```python
>>> import numpy as np
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import LabelPropagation

label_prop_model = LabelPropagation()
iris = datasets.load_iris()
>>>
>>>
>>> rng = np.random.RandomState(42)
random_unlabeled_points = rng.rand(len(iris.target)) < 0.3
labels = np.copy(iris.target)
labels[random_unlabeled_points] = -1
label_prop_model.fit(iris.data, labels)
```

Methods

- **fit**(self, X, y) Fit a semi-supervised label propagation model based
- **get_params**(self[, deep]) Get parameters for this estimator.
- **predict**(self, X) Performs inductive inference across the model.
- **predict_proba**(self, X) Predict probability for each possible outcome.
- **score**(self, X, y[, sample_weight]) Return the mean accuracy on the given test data and labels.
- **set_params**(self, **params) Set the parameters of this estimator.

- **__init__**(self, kernel='rbf', gamma=20, n_neighbors=7, max_iter=1000, tol=0.001, n_jobs=None)
  Initialize self. See help(type(self)) for accurate signature.

- **fit**(self, X, y)
  Fit a semi-supervised label propagation model based
  All the input data is provided matrix X (labeled and unlabeled) and corresponding label matrix y with a
  dedicated marker value for unlabeled samples.

  **Parameters**

  - **X**[array-like of shape (n_samples, n_features)] A {n_samples by n_samples} size matrix
    will be created from this
  - **y**[array_like, shape = [n_samples]] n_labeled_samples (unlabeled points are marked as -1)
    All unlabeled samples will be transductively assigned labels

  **Returns**

  - **self**[returns an instance of self.]

- **get_params**(self, deep=True)
  Get parameters for this estimator.

  **Parameters**

  - **deep**[bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

  **Returns**

  - **params**[mapping of string to any] Parameter names mapped to their values.

- **predict**(self, X)
  Performs inductive inference across the model.
Parameters

- **X** [array-like of shape (n_samples, n_features)]

Returns

- **y** [array_like, shape = [n_samples]] Predictions for input data

**predict_proba** (self, X)

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in X and each possible outcome seen during training (categorical distribution).

Parameters

- **X** [array-like of shape (n_samples, n_features)]

Returns

- **probabilities** [array, shape = [n_samples, n_classes]] Normalized probability distributions across class labels

**score** (self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

### 7.35.2 sklearn.semi_supervised.LabelSpreading

**class sklearn.semi_supervised.LabelSpreading** (kernel='rbf', gamma=20, n_neighbors=7, alpha=0.2, max_iter=30, tol=0.001, n_jobs=None)

LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.
Parameters

- **kernel** [{'knn', 'rbf', callable}] String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape [n_samples, n_features], and return a [n_samples, n_samples] shaped weight matrix.
- **gamma** [float] parameter for rbf kernel
- **n_neighbors** [integer > 0] parameter for knn kernel
- **alpha** [float] Clamping factor. A value in (0, 1) that specifies the relative amount that an instance should adopt the information from its neighbors as opposed to its initial label. alpha=0 means keeping the initial label information; alpha=1 means replacing all initial information.
- **max_iter** [integer] maximum number of iterations allowed
- **tol** [float] Convergence tolerance: threshold to consider the system at steady state
- **n_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

- **X_** [array, shape = [n_samples, n_features]] Input array.
- **classes_** [array, shape = [n_classes]] The distinct labels used in classifying instances.
- **label_distributions_** [array, shape = [n_samples, n_classes]] Categorical distribution for each item.
- **transduction_** [array, shape = [n_samples]] Label assigned to each item via the transduction.
- **n_iter_** [int] Number of iterations run.

### `__init__` (self, kernel='rbf', gamma=20, n_neighbors=7, alpha=0.2, max_iter=30, tol=0.001, n_jobs=None)

Initialize self. See `help(type(self))` for accurate signature.

### `fit (self, X, y)`

Fit a semi-supervised label propagation model based on X and y.

All the input data is provided matrix X (labeled and unlabeled) and corresponding label matrix y with a dedicated marker value for unlabeled samples.

**Parameters**

- **X**  
  [array-like of shape (n_samples, n_features)]  
  A `{n_samples by n_samples}` size matrix will be created from this.

- **y**  
  [array_like, shape = [n_samples]]  
  n_labeled_samples (unlabeled points are marked as -1)

**Returns**

- **self**  
  [returns an instance of self.]

### `get_params (self, deep=True)`

Get parameters for this estimator.

**Parameters**

- **deep**  
  [bool, default=True]  
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**  
  [mapping of string to any]  
  Parameter names mapped to their values.

### `predict (self, X)`

Performs inductive inference across the model.

**Parameters**

- **X**  
  [array-like of shape (n_samples, n_features)]

**Returns**

- **y**  
  [array_like, shape = [n_samples]]  
  Predictions for input data

### `predict_proba (self, X)`

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in X and each possible outcome seen during training (categorical distribution).

**Parameters**
X [array-like of shape (n_samples, n_features)]

Returns

probabilities [array, shape = [n_samples, n_classes]] Normalized probability distributions across class labels

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

**sklearn.svm.LinearSVC**

```python
class sklearn.svm.LinearSVC(penalty='l2', loss='squared_hinge', dual=True, tol=0.0001, C=1.0, multi_class='ovr', fit_intercept=True, intercept_scaling=1, class_weight=None, verbose=0, random_state=None, max_iter=1000)
```

Linear Support Vector Classification.

Similar to SVC with parameter kernel=’linear’, but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

Read more in the User Guide.

**Parameters**

- `penalty` [str, ‘l1’ or ‘l2’ (default=’l2’)] Specifies the norm used in the penalization. The ‘l2’ penalty is the standard used in SVC. The ‘l1’ leads to `coef_` vectors that are sparse.

- `loss` [str, ‘hinge’ or ‘squared_hinge’ (default=’squared_hinge’)]: Specifies the loss function. ‘hinge’ is the standard SVM loss (used e.g. by the SVC class) while ‘squared_hinge’ is the square of the hinge loss.

- `dual` [bool, (default=True)]: Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

- `tol` [float, optional (default=1e-4)]: Tolerance for stopping criteria.

- `C` [float, optional (default=1.0)]: Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.

- `multi_class` [str, ‘ovr’ or ‘crammer_singer’ (default=’ovr’)]: Determines the multi-class strategy if y contains more than two classes. "ovr" trains n_classes one-vs-rest classifiers, while "crammer_singer" optimizes a joint objective over all classes. While crammer_singer is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If "crammer_singer" is chosen, the options loss, penalty and dual will be ignored.

- `fit_intercept` [bool, optional (default=True)]: Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

- `intercept_scaling` [float, optional (default=1)]: When self.fit_intercept is True, instance vector x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to 11/2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

7.36. sklearn.svm: Support Vector Machines 2465
class_weight [[dict, ‘balanced’], optional] Set the parameter C of class i to class_weight[i] * C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

verbose [int, (default=0)] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data for the dual coordinate descent (if dual=True). When dual=False the underlying implementation of LinearSVC is not random and random_state has no effect on the results. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

max_iter [int, (default=1000)] The maximum number of iterations to be run.

Attributes

coef_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

c.___ is a readonly property derived from raw_coef_ that follows the internal memory layout of liblinear.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

classes_ [array of shape (n_classes,)] The unique classes labels.

See also:

SVC Implementation of Support Vector Machine classifier using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does. Furthermore SVC multi-class mode is implemented using one vs one scheme while LinearSVC uses one vs the rest. It is possible to implement one vs the rest with SVC by using the sklearn.multiclass.OneVsRestClassifier wrapper. Finally SVC can fit dense data without memory copy if the input is C-contiguous. Sparse data will still incur memory copy though.

sklearn.linear_model.SGDClassifier SGDClassifier can optimize the same cost function as LinearSVC by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

The underlying implementation, liblinear, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

LIBLINEAR: A Library for Large Linear Classification

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_features=4, random_state=0)

>>> clf = LinearSVC(random_state=0, tol=1e-5)

>>> clf.fit(X, y)
LinearSVC(random_state=0, tol=1e-05)

>>> print(clf.coef_)
[[0.085... 0.394... 0.498... 0.375...]]

>>> print(clf.intercept_)
[0.284...]

>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

Methods

- `decision_function(self, X)` Predict confidence scores for samples.
- `densify(self)` Convert coefficient matrix to dense array format.
- `fit(self, X, y[, sample_weight])` Fit the model according to the given training data.
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, X)` Predict class labels for samples in X.
- `score(self, X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(self, **params)` Set the parameters of this estimator.
- `sparsify(self)` Convert coefficient matrix to sparse format.

```python
__init__(self, penalty='l2', loss='squared_hinge', dual=True, tol=0.0001, C=1.0, multi_class='ovr', fit_intercept=True, intercept_scaling=1, class_weight=None, verbose=0, random_state=None, max_iter=1000)

Initialize self. See help(type(self)) for accurate signature.

decision_function(self, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

- `X` [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- `array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)` Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify(self)

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is
required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self  Fitted estimator.

fit (self, X, y, sample_weight=None)
Fit the model according to the given training data.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y  [array-like of shape (n_samples,)] Target vector relative to X.

sample_weight  [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns

self  [object] An instance of the estimator.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict class labels for samples in X.

Parameters

X  [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C  [array, shape [n_samples]] Predicted class label per sample.

score (self, X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**sparsify** (self)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

**Returns**

self Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

**Examples using sklearn.svm.LinearSVC**

- Explicit feature map approximation for RBF kernels
- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Pipeline Anova SVM
- Univariate Feature Selection
- Balance model complexity and cross-validated score
- Precision-Recall
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Column Transformer with Heterogeneous Data Sources
- Feature discretization
- Release Highlights for scikit-learn 0.22
- Plot the support vectors in LinearSVC
- Plot different SVM classifiers in the iris dataset
- Scaling the regularization parameter for SVCs
- Classification of text documents using sparse features
sklearn.svm.LinearSVR

class sklearn.svm.LinearSVR(epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive',
                           fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0,
                           random_state=None, max_iter=1000)

Linear Support Vector Regression.

Similar to SVR with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it
has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of
samples.

This class supports both dense and sparse input.

Read more in the User Guide.

New in version 0.16.

Parameters

- **epsilon** [float, optional (default=0.0)] Epsilon parameter in the epsilon-insensitive loss function.
  Note that the value of this parameter depends on the scale of the target variable y. If unsure, set epsilon=0.

- **tol** [float, optional (default=1e-4)] Tolerance for stopping criteria.

- **C** [float, optional (default=1.0)] Regularization parameter. The strength of the regularization is
  inversely proportional to C. Must be strictly positive.

- **loss** [string, optional (default='epsilon_insensitive')] Specifies the loss function. The epsilon-
  insensitive loss (standard SVR) is the L1 loss, while the squared epsilon-insensitive loss
  ('squared_epsilon_insensitive') is the L2 loss.

- **fit_intercept** [boolean, optional (default=True)] Whether to calculate the intercept for this
  model. If set to false, no intercept will be used in calculations (i.e. data is expected to
  be already centered).

- **intercept_scaling** [float, optional (default=1)] When self.fit_intercept is True, instance vec-
  tor x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value
  equals to intercept_scaling is appended to the instance vector. The intercept becomes
  intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to
  l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic
  feature weight (and therefore on the intercept) intercept_scaling has to be increased.

- **dual** [bool, (default=True)] Select the algorithm to either solve the dual or primal optimization
  problem. Prefer dual=False when n_samples > n_features.

- **verbose** [int, (default=0)] Enable verbose output. Note that this setting takes advantage of a per-
  process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded
  context.

- **random_state** [int, RandomState instance or None, optional (default=None)] The seed of the
  pseudo random number generator to use when shuffling the data. If int, random_state is
  the seed used by the random number generator; If RandomState instance, random_state is
  the random number generator; If None, the random number generator is the RandomState
  instance used by np.random.

- **max_iter** [int, (default=1000)] The maximum number of iterations to be run.

Attributes

- **coef_** [array, shape = [n_features] if n_classes == 2 else [n_classes, n_features]] Weights as-
  signed to the features (coefficients in the primal problem). This is only available in the case
  of a linear kernel.

2470 Chapter 7. API Reference
coef_ is a readonly property derived from raw_coef_ that follows the internal memory layout of liblinear.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] Maximum number of iterations run across all classes.

See also:

**LinearSVC** Implementation of Support Vector Machine classifier using the same library as this class (liblinear).

**SVR** Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.

**sklearn.linear_model.SGDRegressor** SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Examples

```python
>>> from sklearn.svm import LinearSVR
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, random_state=0)
>>> regr = LinearSVR(random_state=0, tol=1e-5)
>>> regr.fit(X, y)
LinearSVR(random_state=0, tol=1e-05)

>>> print(regr.coef_)
[16.35... 26.91... 42.30... 60.47...]

>>> print(regr.intercept_)
[-4.29...]

>>> print(regr.predict([[0, 0, 0, 0]]))
[-4.29...]
```

Methods

- `fit(self, X, y[, sample_weight])` Fit the model according to the given training data.
- `get_params(self[, deep])` Get parameters for this estimator.
- `predict(self, X)` Predict using the linear model.
- `score(self, X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(self, **params)` Set the parameters of this estimator.

```python
__init__(self, epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive', fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0, random_state=None, max_iter=1000)
```

Initialize self. See help(type(self)) for accurate signature.

```python
fit(self, X, y, sample_weight=None)
```
Fit the model according to the given training data.

**Parameters**

**X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

**y** [array-like of shape (n_samples,)] Target vector relative to X
sample_weight [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns
self [object]

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Predict using the linear model.

Parameters
X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (self, X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes
The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

`sklearn.svm.NuSVC`

    class sklearn.svm.NuSVC (nu=0.5, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None)

    Nu-Support Vector Classification.

    Similar to SVC but uses a parameter to control the number of support vectors.

    The implementation is based on libsvm.

    Read more in the User Guide.

**Parameters**

- `nu` [float, optional (default=0.5)] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1].

- `kernel` [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

- `degree` [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

- `gamma` [‘scale’, ‘auto’ or float, optional (default=‘scale’)] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
  
  • if `gamma='scale'` (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
  
  • if ‘auto’, uses 1 / n_features.

    Changed in version 0.22: The default value of `gamma` changed from ‘auto’ to ‘scale’.

- `coef0` [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

- `shrinking` [boolean, optional (default=True)] Whether to use the shrinking heuristic.

- `probability` [boolean, optional (default=False)] Whether to enable probability estimates. This must be enabled prior to calling `fit`, will slow down that method as it internally uses 5-fold cross-validation, and `predict_proba` may be inconsistent with `predict`. Read more in the User Guide.

- `tol` [float, optional (default=1e-3)] Tolerance for stopping criterion.

- `cache_size` [float, optional] Specify the size of the kernel cache (in MB).
class_weight [[dict, ‘balanced’], optional] Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies as n_samples / (n_classes * np.bincount(y))

verbose [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape ['ovo', 'ovr', default='ovr'] Whether to return a one-vs-rest ('ovr') decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2).

Changed in version 0.19: decision_function_shape is ‘ovr’ by default.

New in version 0.17: decision_function_shape='ovr' is recommended.

Changed in version 0.17: Deprecated decision_function_shape='ovo' and None.

break_ties [bool, optional (default=False)] If true, decision_function_shape='ovr', and number of classes > 2, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator used when shuffling the data for probability estimates. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

support_ [array-like of shape (n_SV)] Indices of support vectors.

support_vectors_ [array-like of shape (n_SV, n_features)] Support vectors.

n_support_ [array-like, dtype=int32, shape = [n_class]] Number of support vectors for each class.

dual_coef_ [array, shape = [n_class-1, n_SV]] Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

ccoef_ [array, shape = [n_class * (n_class-1) / 2, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

ccoef_ is readonly property derived from dual_coef_ and support_vectors_.

intercept_ [ndarray of shape (n_class * (n_class-1) / 2,)] Constants in decision function.

classes_ [array of shape (n_classes,)] The unique classes labels.

fit_status_ [int] 0 if correctly fitted, 1 if the algorithm did not converge.

probA_ [ndarray, shape of (n_class * (n_class-1) / 2,)]
probB_ [ndarray of shape (n_class * (n_class-1) / 2,)] If probability=True, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If probability=False, it’s an empty array. Platt scaling uses the logistic function 1 / (1 + exp(decision_value * probA_ + probB_)) where probA_ and probB_ are learned from the dataset [R9709ce4a60d3-2]. For more information on the multiclass case and training procedure see section 8 of [R9709ce4a60d3-1].

class_weight_ [ndarray of shape (n_class,)] Multipliers of parameter C of each class. Computed based on the class_weight parameter.

shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

__init__ (self, nu=0.5, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None)

Initialize self. See help(type(self)) for accurate signature.

decision_function (self, X)

Evaluates the decision function for the samples in X.

Parameters
X [array-like, shape (n_samples, n_features)]

Returns

X [array-like, shape (n_samples, n_classes * (n_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes).

Notes

If decision_function_shape='ovo', the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (coef_). See also this question for further details. If decision_function_shape='ovr', the decision function is a monotonic transformation of ovo decision function.

fit (self, X, y, sample_weight=None)
Fit the SVM model according to the given training data.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y [array-like, shape (n_samples,)] Target values (class labels in classification, real numbers in regression)

sample_weight [array-like, shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns

self [object]

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

generate (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]
Returns

y_pred [array, shape (n_samples,)] Class labels for samples in X.

property predict_log_proba

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters

X [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns

T [array-like, shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

property predict_proba

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters

X [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns

T [array-like, shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

score(self, X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.svm.NuSVC

- **Non-linear SVM**

**sklearn.svm.NuSVR**

**class** *sklearn.svm.NuSVR (nu=0.5, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, tol=0.001, cache_size=200, verbose=False, max_iter=-1)*

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter nu to control the number of support vectors. However, unlike NuSVC, where nu replaces C, here nu replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the **User Guide**.

**Parameters**

- **nu** [float, optional] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

- **C** [float, optional (default=1.0)] Penalty parameter C of the error term.

- **kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

- **degree** [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

- **gamma** [‘scale’, ‘auto’] or float, optional (default=‘scale’) Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

  - if **gamma** = ‘scale’ (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,

  - if ‘auto’, uses 1 / n_features.

  Changed in version 0.22: The default value of **gamma** changed from ‘auto’ to ‘scale’.

- **coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.
shrinking [boolean, optional (default=True)] Whether to use the shrinking heuristic.
tol [float, optional (default=1e-3)] Tolerance for stopping criterion.
cache_size [float, optional] Specify the size of the kernel cache (in MB).
verbose [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.
max_iter [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

Attributes

support_ [array-like of shape (n_SV)] Indices of support vectors.
support_vectors_ [array-like of shape (n_SV, n_features)] Support vectors.
dual_coef_ [array, shape = [1, n_SV]] Coefficients of the support vector in the decision function.
coef_ [array, shape = [1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coef_ is readonly property derived from dual_coef_ and support_vectors_.
intercept_ [array, shape = [1]] Constants in decision function.

Examples

```python
golden >> from sklearn.svm import NuSVR
golden >> import numpy as np
golden >> n_samples, n_features = 10, 5
golden >> np.random.seed(0)
golden >> y = np.random.randn(n_samples)
golden >> X = np.random.randn(n_samples, n_features)
golden >> clf = NuSVR(C=1.0, nu=0.1)
golden >> clf.fit(X, y)
NuSVR(nu=0.1)
```

Methods

```python
def fit(self, X, y[, sample_weight])
Fit the SVM model according to the given training data.
def get_params(self[, deep])
Get parameters for this estimator.
```

tol=0.001, cache_size=200, verbose=False, max_iter=-1)

Initialize self. See help(type(self)) for accurate signature.

`fit` (self, X, y, sample_weight=None)

Fit the SVM model according to the given training data.

**Parameters**

- `X` [{array-like, sparse matrix}, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- `y` [array-like, shape (n_samples,)] Target values (class labels in classification, real numbers in regression)
- `sample_weight` [array-like, shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- `self` [object]

**Notes**

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

`get_params` (self, deep=True)

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names mapped to their values.

`predict` (self, X)

Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

**Parameters**

- `X` [{array-like, sparse matrix}, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- `y_pred` [array, shape (n_samples,)]
score(self, X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean()}) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict(X) wrt. $y$.

Notes

The $R^2$ score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with $r2\_score$. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call $r2\_score$ directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params(self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [object] Estimator instance.

Examples using sklearn.svm.NuSVR

- Model Complexity Influence

sklearn.svm.OneClassSVM

class sklearn.svm.OneClassSVM(kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache_size=200, verbose=False, max_iter=-1)

Unsupervised Outlier Detection.

Estimate the support of a high-dimensional distribution.
The implementation is based on libsvm.

Read more in the User Guide.

Parameters

- **kernel** [string, optional (default=’rbf’)] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

- **degree** [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

- **gamma** [{'scale', ‘auto’} or float, optional (default=’scale’)] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
  - if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
  - if ‘auto’, uses 1 / n_features.

  Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

- **coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

- **tol** [float, optional] Tolerance for stopping criterion.

- **nu** [float, optional] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

- **shrinking** [boolean, optional] Whether to use the shrinking heuristic.

- **cache_size** [float, optional] Specify the size of the kernel cache (in MB).

- **verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

- **max_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

Attributes

- **support_** [array-like of shape (n_SV)] Indices of support vectors.

- **support_vectors_** [array-like of shape (n_SV, n_features)] Support vectors.

- **dual_coef_** [array, shape = [1, n_SV]] Coefficients of the support vectors in the decision function.

- **coef_** [array, shape = [1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

  coef_ is readonly property derived from dual_coef_ and support_vectors_

- **intercept_** [array, shape = [1,]] Constant in the decision function.

- **offset_** [float] Offset used to define the decision function from the raw scores. We have the relation: decision_function = score_samples - offset_. The offset is the opposite of intercept_ and is provided for consistency with other outlier detection algorithms.

- **fit_status_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)
Examples

```python
>>> from sklearn.svm import OneClassSVM
>>> X = [[0], [0.44], [0.45], [0.46], [1]]
>>> clf = OneClassSVM(gamma='auto').fit(X)
>>> clf.predict(X)
array([-1, 1, 1, 1, -1])
>>> clf.score_samples(X) # doctest: +ELLIPSIS
array([1.7798..., 2.0547..., 2.0556..., 2.0561..., 1.7332...])
```

__init__(self, kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache_size=200, verbose=False, max_iter=-1)

Initialize self. See help(type(self)) for accurate signature.

decision_function (self, X)

Signed distance to the separating hyperplane.

Parameters

- **X**: array-like, shape (n_samples, n_features)

Returns

- **dec**: array-like, shape (n_samples,) Returns the decision function of the samples.

fit (self, X, y=None, sample_weight=None, **params)

Detects the soft boundary of the set of samples X.

Parameters

- **X**: [{array-like, sparse matrix}, shape (n_samples, n_features)] Set of samples, where n_samples is the number of samples and n_features is the number of features.
- **sample_weight**: array-like, shape (n_samples,) Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.
- **y**: [Ignored] not used, present for API consistency by convention.

Returns

- **self**: [object]

Notes

If X is not a C-ordered contiguous array it is copied.
**fit_predict** *(self, X, y=None)*  
Perform fit on X and returns labels for X.  
Returns -1 for outliers and 1 for inliers.  

**Parameters**  
  X [ndarray, shape (n_samples, n_features)] Input data.  
  y [Ignored] Not used, present for API consistency by convention.  

**Returns**  
  y [ndarray, shape (n_samples,)] 1 for inliers, -1 for outliers.  

**get_params** *(self, deep=True)*  
Get parameters for this estimator.  

**Parameters**  
  deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.  

**Returns**  
  params [mapping of string to any] Parameter names mapped to their values.  

**predict** *(self, X)*  
Perform classification on samples in X.  
For a one-class model, +1 or -1 is returned.  

**Parameters**  
  X [{array-like, sparse matrix}, shape (n_samples, n_features)] For kernel=’precomputed’, the expected shape of X is [n_samples_test, n_samples_train]  

**Returns**  
  y_pred [array, shape (n_samples,)] Class labels for samples in X.  

**score_samples** *(self, X)*  
Raw scoring function of the samples.  

**Parameters**  
  X [array-like, shape (n_samples, n_features)]  

**Returns**  
  score_samples [array-like, shape (n_samples,)] Returns the (unshifted) scoring function of the samples.  

**set_params** *(self, **params)*  
Set the parameters of this estimator.  
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.  

**Parameters**  
  **params [dict] Estimator parameters.  

**Returns**  
  self [object] Estimator instance.
Examples using `sklearn.svm.OneClassSVM`

- Libsvm GUI

`sklearn.svm.SVC`

class `sklearn.svm.SVC`(
    C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True,
    probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False,
    max_iter=-1, decision_function_shape='ovr', break_ties=False,
    random_state=None)

C-Support Vector Classification.

The implementation is based on libsvm. The fit time scales at least quadratically with the number of samples and may be impractical beyond tens of thousands of samples. For large datasets consider using `sklearn.svm.LinearSVC` or `sklearn.linear_model.SGDClassifier` instead, possibly after a `sklearn.kernel_approximation.Nystroem` transformer.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how `gamma`, `coef0` and `degree` affect each other, see the corresponding section in the narrative documentation: Kernel functions.

Read more in the User Guide.

**Parameters**

- **C** [float, optional (default=1.0)] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.

- **kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape (n_samples, n_samples).

- **degree** [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

- **gamma** [‘scale’, ‘auto’] or float, optional (default=‘scale’) Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
  - if `gamma='scale'` (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
  - if ‘auto’, uses 1 / n_features.

  Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

- **coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

- **shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.

- **probability** [boolean, optional (default=False)] Whether to enable probability estimates. This must be enabled prior to calling fit, will slow down that method as it internally uses 5-fold cross-validation, and predict_proba may be inconsistent with predict. Read more in the User Guide.

- **tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.

- **cache_size** [float, optional] Specify the size of the kernel cache (in MB).
class_weight \[(dict, ‘balanced’), optional\] Set the parameter $C$ of class $i$ to $\text{class_weight}[i]*C$ for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of $y$ to automatically adjust weights inversely proportional to class frequencies in the input data as $n_{\text{samples}} / (n_{\text{classes}} * \text{np.bincount}(y))$

verbose \[bool, default: False\] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter \[int, optional (default=-1)\] Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape \[‘ovo’, ‘ovr’, default=’ovr’\] Whether to return a one-vs-rest (‘ovr’) decision function of shape $(n_{\text{samples}}, n_{\text{classes}})$ as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape $(n_{\text{samples}}, n_{\text{classes}} * (n_{\text{classes}} - 1) / 2)$. However, one-vs-one (‘ovo’) is always used as multi-class strategy.

Changed in version 0.19: decision_function_shape is ‘ovr’ by default.

New in version 0.17: decision_function_shape=’ovr’ is recommended.

Changed in version 0.17: Deprecated decision_function_shape=’ovo’ and None.

break_ties \[bool, optional (default=False)\] If true, decision_function_shape=’ovr’, and number of classes $> 2$, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

random_state \[int, RandomState instance or None, optional (default=None)\] The seed of the pseudo random number generator used when shuffling the data for probability estimates. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

support_ \[array-like of shape (n_{SV})\] Indices of support vectors.

support_vectors_ \[array-like of shape (n_{SV}, n_{features})\] Support vectors.

n_support_ \[array-like, dtype=int32, shape = [n_class]] Number of support vectors for each class.

dual_coef_ \[array, shape = [n_class-1, n_{SV}]\] Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

coef_ \[array, shape = [n_class * (n_class-1) / 2, n_{features}]\] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coeff_ is a readonly property derived from dual_coef_ and support_vectors_.

intercept_ \[ndarray of shape (n_class * (n_class-1) / 2,)\] Constants in decision function.

fit_status_ \[int\] 0 if correctly fitted, 1 otherwise (will raise warning)

classes_ \[array of shape (n_classes,)\] The classes labels.

probA_ \[array, shape = [n_class * (n_class-1) / 2]]

probB_ \[array, shape = [n_class * (n_class-1) / 2]] If probability=True, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values.
If `probability=False`, it's an empty array. Platt scaling uses the logistic function 
\[
\frac{1}{1 + \exp(decision\_value \times probA_ + probB_)}
\]
where `probA_` and `probB_` are learned from the dataset [R20c70293ef72-2]. For more information on the multiclass case and training procedure see section 8 of [R20c70293ef72-1].

**class_weight_** [ndarray of shape (n_class,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

**shape_fit_** [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

### Examples

```python
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.svm import SVC
>>> clf = SVC(gamma='auto')
>>> clf.fit(X, y)
SVC(gamma='auto')
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

### Methods

- **decision_function** *(self, X)* Evaluates the decision function for the samples in X.
- **fit** *(self, X, y[, sample_weight])* Fit the SVM model according to the given training data.
- **get_params** *(self[, deep])* Get parameters for this estimator.
- **predict** *(self, X)* Perform classification on samples in X.
- **score** *(self, X, y[, sample_weight])* Return the mean accuracy on the given test data and labels.
- **set_params** *(self, **params)* Set the parameters of this estimator.

### __init__ *(self, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None)*

Initialize self. See help(type(self)) for accurate signature.

- **decision_function** *(self, X)* Evaluates the decision function for the samples in X.

### Parameters

- **C**
- **kernel**
- **degree**
- **gamma**
- **coef0**
- **shrinking**
- **probability**
- **tol**
- **cache_size**
- **class_weight**
- **verbose**
- **max_iter**
- **decision_function_shape**
- **break_ties**
- **random_state**
X [array-like, shape (n_samples, n_features)]

Returns

X [array-like, shape (n_samples, n_classes * (n_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes).

Notes

If decision_function_shape='ovo', the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (coef_). See also this question for further details. If decision_function_shape='ovr', the decision function is a monotonic transformation of ovo decision function.

fit (self, X, y, sample_weight=None)
Fit the SVM model according to the given training data.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y [array-like, shape (n_samples,)] Target values (class labels in classification, real numbers in regression)

sample_weight [array-like, shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns

self [object]

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deepe [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X)
Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]
Returns

```
y_pred [array, shape (n_samples,)] Class labels for samples in X.
```

**property predict_log_proba**

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

```
X [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]
```

**Returns**

```
T [array-like, shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.
```

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**property predict_proba**

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

```
X [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]
```

**Returns**

```
T [array-like, shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.
```

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**score**

```
score (self, X, y, sample_weight=None)
```

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

```
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.
```

**Returns**
**score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params** (*self, **params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [object] Estimator instance.

**Examples using sklearn.svm.SVC**

- Libsvm GUI

**sklearn.svm.SVR**

class sklearn.svm.SVR(*kernel=C, degree=3, gamma='scale', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache_size=200, verbose=False, max_iter=-1)*

Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to datasets with more than a couple of 10000 samples. For large datasets consider using `sklearn.svm.LinearSVR` or `sklearn.linear_model.SGDRegressor` instead, possibly after a `sklearn.kernel_approximation.Nystroem` transformer.

Read more in the User Guide.

**Parameters**

- **kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.
- **degree** [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.
- **gamma** [['scale', 'auto'] or float, optional (default='scale')] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
  - if `gamma='scale'` (default) is passed then it uses `1 / (n_features * X.var())` as value of `gamma`,
  - if ‘auto’, uses `1 / n_features`.
  Changed in version 0.22: The default value of `gamma` changed from ‘auto’ to ‘scale’.
- **coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.
- **tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.
- **C** [float, optional (default=1.0)] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.
epsilon [float, optional (default=0.1)] Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.

shrinking [boolean, optional (default=True)] Whether to use the shrinking heuristic.

cache_size [float, optional] Specify the size of the kernel cache (in MB).

verbose [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

Attributes

- support_ [array-like of shape (n_SV)] Indices of support vectors.
- support_vectors_ [array-like of shape (n_SV, n_features)] Support vectors.
- dual_coef_ [array, shape = [1, n_SV]] Coefficients of the support vector in the decision function.
- coef_ [array, shape = [1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.
  - coef_ is readonly property derived from dual_coef_ and support_vectors_.

- fit_status_ [int] 0 if correctly fitted, 1 otherwise (will raise warning)
- intercept_ [array, shape = [1]] Constants in decision function.

Examples

```python
>>> from sklearn.svm import SVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = SVR(C=1.0, epsilon=0.2)
>>> clf.fit(X, y)
SVR(epsilon=0.2)
```

Methods

7.36. sklearn.svm: Support Vector Machines 2491
**fit** (self, X, y[, sample_weight])  
Fit the SVM model according to the given training data.

**get_params** (self[, deep])  
Get parameters for this estimator.

**predict** (self, X)  
Perform regression on samples in X.

**score** (self, X, y[, sample_weight])  
Return the coefficient of determination R^2 of the prediction.

**set_params** (self, **params)  
Set the parameters of this estimator.

**__init__** (self, kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache_size=200, verbose=False, max_iter=-1)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (self, X, y, sample_weight=None)  
Fit the SVM model according to the given training data.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) Training vectors, where
  n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- **y** (array-like, shape (n_samples,)) Target values (class labels in classification, real numbers in regression)
- **sample_weight** (array-like, shape (n_samples,)) Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self** [object]

**Notes**

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get_params** (self, deep=True)  
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict** (self, X)  
Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**
**y_pred** [array, shape (n_samples,)]

**score** *(self, X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $\sum ((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum (y_{true} - \text{y_{true}.mean()})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. $y$.

**Notes**

The $R^2$ score used when calling **score** on a regressor will use **multioutput='uniform_average'** from version 0.23 to keep consistent with **r2_score**. This will influence the **score** method of all the multioutput regressors (except for **MultiOutputRegressor**). To specify the default value manually and avoid the warning, please either call **r2_score** directly or make a custom scorer with **make_scorer** (the built-in scorer **'r2'** uses **multioutput='uniform_average'**).

**set_params** *(self, **params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**Examples using sklearn.svm.SVR**

- *Comparison of kernel ridge regression and SVR*
- *Prediction Latency*
- *Support Vector Regression (SVR) using linear and non-linear kernels*

**svm.l1_min_c(X, y, [loss, fit_intercept, ...])**

Return the lowest bound for $C$ such that for $C$ in (l1_min_C, infinity) the model is guaranteed not to be empty.
sklearn.svm.l1_min_c

sklearn.svm.l1_min_c(X, y, loss='squared_hinge', fit_intercept=True, intercept_scaling=1.0)

Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty. This applies to L1 penalized classifiers, such as LinearSVC with penalty='l1' and linear_model.LogisticRegression with penalty='l1'.

This value is valid if class_weight parameter in fit() is not set.

Parameters

X [[array-like or sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array, shape = [n_samples]] Target vector relative to X

loss [[{'squared_hinge', 'log'}, default 'squared_hinge'] Specifies the loss function. With 'squared_hinge' it is the squared hinge loss (a.k.a. L2 loss). With 'log' it is the loss of logistic regression models.

fit_intercept [bool, default: True] Specifies if the intercept should be fitted by the model. It must match the fit() method parameter.

intercept_scaling [float, default: 1] when fit_intercept is True, instance vector x becomes [x, intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. It must match the fit() method parameter.

Returns

l1_min_c [float] minimum value for C

Examples using sklearn.svm.l1_min_c

- Regularization path of L1-Logistic Regression

7.37 sklearn.tree: Decision Trees

The sklearn.tree module includes decision tree-based models for classification and regression.

User guide: See the Decision Trees section for further details.

7.37.1 sklearn.tree.DecisionTreeClassifier

class sklearn.tree.DecisionTreeClassifier (criterion='gini', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, presort='deprecated', ccp_alpha=0.0)

A decision tree classifier.

Read more in the User Guide.

Parameters

criterion [“gini”, “entropy”], default=”gini”] The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.

splitter [“best”, “random”], default=”best”] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider min_samples_split as the minimum number.
- If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

min_samples_leaf [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider min_samples_leaf as the minimum number.
- If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_features [int, float or (“auto”, “sqrt”, “log2”), default=None] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and int(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=sqrt(n_features).
• If “sqrt”, then \( \text{max\_features} = \sqrt{\text{n\_features}} \).

• If “log2”, then \( \text{max\_features} = \log_2(\text{n\_features}) \).

• If None, then \( \text{max\_features} = \text{n\_features} \).

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than \( \text{max\_features} \) features.

**random_state** [int or RandomState, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by \text{np.random}.

**max_leaf_nodes** [int, default=None] Grow a tree with \( \text{max\_leaf\_nodes} \) in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t\_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t\_L}}{N_t} \times \text{left\_impurity} \right)
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t\_L} \) is the number of samples in the left child, and \( N_{t\_R} \) is the number of samples in the right child.

\( N, N_t, N_{t\_R} \) and \( N_{t\_L} \) all refer to the weighted sum, if \text{sample\_weight} is passed.

New in version 0.19.

**min_impurity_split** [float, default=1e-7] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.10: \text{min\_impurity\_split} has been deprecated in favor of \text{min\_impurity\_decrease} in 0.19. The default value of \text{min\_impurity\_split} will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use \text{min\_impurity\_decrease} instead.

**class_weight** [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form \{class\_label: weight\}. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of \( y \).

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be \{0: \{1: 1, 1: 1\}, \{0: 1, 1: 5\}, \{0: 1, 1: 1\}, \{0: 1, 1: 1\} \} instead of \{1:1, 2:5, 3:1, 4:1\}.

The “balanced” mode uses the values of \( y \) to automatically adjust weights inversely proportional to class frequencies in the input data as \( \text{n\_samples} / (\text{n\_classes} \times \text{np.bincount}(y)) \)

For multi-output, the weights of each column of \( y \) will be multiplied.

Note that these weights will be multiplied with \text{sample\_weight} (passed through the fit method) if \text{sample\_weight} is specified.

**presort** [deprecated, default='deprecated'] This parameter is deprecated and will be removed in v0.24.
**Deprecated since version 0.22.**

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than **ccp_alpha** will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**Attributes**

- **classes_** [ndarray of shape (n_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.

- **max_features_** [int] The inferred value of max_features.

- **n_classes_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).

- **n_features_** [int] The number of features when fit is performed.

- **n_outputs_** [int] The number of outputs when fit is performed.

- **tree_** [Tree] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and Understanding the decision tree structure for basic usage of these attributes.

See also:

**DecisionTreeRegressor** A decision tree regressor.

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and max_features=n_features, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

__init__(self, criterion='gini', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, presort='deprecated', ccp_alpha=0.0) Initialize self. See help(type(self)) for accurate signature.

apply (self, X, check_input=True) Return the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

- X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.
- check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

- X_leaves array-like of shape (n_samples,) For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

cost_complexity_pruning_path (self, X, y, sample_weight=None) Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.
Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path  [Bunch] Dictionary-like object, with attributes:

ccp_alphas  [ndarray] Effective alphas of subtree during pruning.

impurities  [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path  (self, X, check_input=True)

Return the decision path in the tree.

New in version 0.18.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator  [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns

feature_importances_  [ndarray of shape (n_features,)] Normalized total reduction of criterion by feature (Gini importance).

fit  (self, X, y, sample_weight=None, check_input=True, X_idx_sorted=None)

Build a decision tree classifier from the training set (X, y).

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted [array-like of shape (n_samples, n_features), default=None] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

self [DecisionTreeClassifier] Fitted estimator.

get_depth (self)
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

self.tree_.max_depth [int] The maximum depth of the tree.

get_n_leaves (self)
Return the number of leaves of the decision tree.

Returns

self.tree_.n_leaves [int] Number of leaves.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.
**predict_log_proba** (*self, X*)

Predict class log-probabilities of the input samples X.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **proba** [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

**predict_proba** (*self, X, check_input=True*)

Predict class probabilities of the input samples X.

The predicted class probability is the fraction of samples of the same class in a leaf.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **proba** [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

**score** (*self, X, y, sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.

- **y** [array-like of shape (n_samples,), or (n_samples, n_outputs)] True labels for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (*self, **params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**
self  [object] Estimator instance.

Examples using sklearn.tree.DecisionTreeClassifier

- Classifier comparison
- Plot the decision surface of a decision tree on the iris dataset
- Post pruning decision trees with cost complexity pruning
- Understanding the decision tree structure
- Plot the decision boundaries of a VotingClassifier
- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees
- Discrete versus Real AdaBoost
- Plot the decision surfaces of ensembles of trees on the iris dataset
- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

7.37.2 sklearn.tree.DecisionTreeRegressor

class sklearn.tree.DecisionTreeRegressor (criterion='mse', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, presort='deprecated', ccp_alpha=0.0)

A decision tree regressor.

Read more in the User Guide.

Parameters

criterion  ["mse", "friedman_mse", "mae"], default="mse"] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion and minimizes the L2 loss using the mean of each terminal node, “friedman_mse”, which uses mean squared error with Friedman’s improvement score for potential splits, and “mae” for the mean absolute error, which minimizes the L1 loss using the median of each terminal node.

New in version 0.18: Mean Absolute Error (MAE) criterion.

splitter  ["best", "random"], default="best"] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

max_depth  [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split  [int or float, default=2] The minimum number of samples required to split an internal node:
• If int, then consider \texttt{min\_samples\_split} as the minimum number.

• If float, then \texttt{min\_samples\_split} is a fraction and \texttt{ceil(min\_samples\_split} * \texttt{n\_samples)} are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

\textbf{min\_samples\_leaf} [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least \texttt{min\_samples\_leaf} training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

• If int, then consider \texttt{min\_samples\_leaf} as the minimum number.

• If float, then \texttt{min\_samples\_leaf} is a fraction and \texttt{ceil(min\_samples\_leaf} * \texttt{n\_samples)} are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

\textbf{min\_weight\_fraction\_leaf} [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when \texttt{sample\_weight} is not provided.

\textbf{max\_features} [int, float or ("auto", "sqrt", "log2"), default=None] The number of features to consider when looking for the best split:

• If int, then consider \texttt{max\_features} features at each split.

• If float, then \texttt{max\_features} is a fraction and \texttt{int(max\_features} * \texttt{n\_features)} features are considered at each split.

• If "auto", then \texttt{max\_features} = \texttt{n\_features}.

• If "sqrt", then \texttt{max\_features} = \texttt{sqrt(n\_features)}.

• If "log2", then \texttt{max\_features} = \texttt{log2(n\_features)}.

• If None, then \texttt{max\_features} = \texttt{n\_features}.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than \texttt{max\_features} features.

\textbf{random\_state} [int or RandomState, default=None] If int, \texttt{random\_state} is the seed used by the random number generator; If RandomState instance, \texttt{random\_state} is the random number generator; If None, the random number generator is the RandomState instance used by np. random.

\textbf{max\_leaf\_nodes} [int, default=None] Grow a tree with \texttt{max\_leaf\_nodes} in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

\textbf{min\_impurity\_decrease} [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (impurity - \frac{N_{t,R}}{N_t} \times right\_impurity - \frac{N_{t,L}}{N_t} \times left\_impurity)
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,R}\) and \(N_{t,L}\) all refer to the weighted sum, if \texttt{sample\_weight} is passed.
New in version 0.19.

**min_impurity_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.

**presort** [deprecated, default='deprecated'] This parameter is deprecated and will be removed in v0.24.

Deprecated since version 0.22.

**ccpAlpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**Attributes**

- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.
- **max_features_** [int] The inferred value of max_features.
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **tree_** [Tree] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and Understanding the decision tree structure for basic usage of these attributes.

See also:

**DecisionTreeClassifier** A decision tree classifier.

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and max_features=n_features, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

`__init__(self, criterion='mse', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, presort='deprecated', ccp_alpha=0.0)`

Initialize self. See help(type(self)) for accurate signature.

`apply(self, X, check_input=True)`

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

- **X**: [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

- **X_leaves**: [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.
cost_complexity_pruning_path(self, X, y, sample_weight=None)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

- **y** ([array-like of shape (n_samples,) or (n_samples, n_outputs)]) The target values (class labels) as integers or strings.

- **sample_weight** ([array-like of shape (n_samples,), default=None]) Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path [Bunch] Dictionary-like object, with attributes:

- **ccp_alphas** [ndarray] Effective alphas of subtree during pruning.

- **impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path(self, X, check_input=True)

Return the decision path in the tree.

New in version 0.18.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns

feature_importances_ [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).

fit(self, X, y, sample_weight=None, check_input=True, X_idx_sorted=None)

Build a decision tree regressor from the training set (X, y).

Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (real numbers). Use dtype=np.float64 and order='C' for maximum efficiency.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted  [array-like of shape (n_samples, n_features), default=None] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

self  [DecisionTreeRegressor] Fitted estimator.

get_depth  (self)
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

self.tree_.max_depth  [int] The maximum depth of the tree.

get_n_leaves  (self)
Return the number of leaves of the decision tree.

Returns

self.tree_.n_leaves  [int] Number of leaves.

get_params  (self, deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

predict  (self, X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

score (self, X, y, sample_weight=None)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling score on a regressor will use multioutput='uniform_average' from version 0.23 to keep consistent with r2_score. This will influence the score method of all the multioutput regressors (except for MultiOutputRegressor). To specify the default value manually and avoid the warning, please either call r2_score directly or make a custom scorer with make_scorer (the built-in scorer 'r2' uses multioutput='uniform_average').

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using sklearn.tree.DecisionTreeRegressor

• **Release Highlights for scikit-learn 0.22**

### 7.37.3 sklearn.tree.ExtraTreeClassifier

```python
class sklearn.tree.ExtraTreeClassifier (criterion='gini', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, ccp_alpha=0.0)
```

An extremely randomized tree classifier.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the [User Guide](#).

**Parameters**

- `criterion` ([“gini”, “entropy”], default=”gini”) The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.
- `splitter` ([“random”, “best”], default=”random”) The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.
- `max_depth` [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.
- `min_samples_split` [int or float, default=2] The minimum number of samples required to split an internal node:
  - If int, then consider `min_samples_split` as the minimum number.
  - If float, then `min_samples_split` is a fraction and `cei(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

- `min_samples_leaf` [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
  - If int, then consider `min_samples_leaf` as the minimum number.
  - If float, then `min_samples_leaf` is a fraction and `cei(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.
min_weight_fraction_leaf  [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_features  [int, float, {“auto”, “sqrt”, “log2”} or None, default=”auto”] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and int(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=sqrt(n_features).
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

random_state  [int or RandomState, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

max_leaf_nodes  [int, default=None] Grow a tree with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

min_impurity_decrease  [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t\_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t\_L}}{N_t} \times \text{left\_impurity})
\]

where N is the total number of samples, N_t is the number of samples at the current node, N_{t\_L} is the number of samples in the left child, and N_{t\_R} is the number of samples in the right child.

N, N_t, N_{t\_R} and N_{t\_L} all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

min_impurity_split  [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Depreciated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use min_impurity_decrease instead.

class_weight  [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form {class_label: weight}. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights
should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as \(n_{\text{samples}} / (n_{\text{classes}} * \text{np.bincount}(y))\)

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**Attributes**

- **classes_** [ndarray of shape (n_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
- **max_features_** [int] The inferred value of max_features.
- **n_classes_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).
- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **tree_** [Tree] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and Understanding the decision tree structure for basic usage of these attributes.

**See also:**

*ExtraTreeRegressor* An extremely randomized tree regressor.

*sklearn.ensemble.ExtraTreesClassifier* An extra-trees classifier.

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

__init__(self, criterion='gini', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, ccp_alpha=0.0)

Initialize self. See help(type(self)) for accurate signature.

apply (self, X, check_input=True)
Return the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

- **X_leaves** [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

cost_complexity_pruning_path (self, X, y, sample_weight=None)
Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

- **y** [array-like of shape (n_samples,)] or (n_samples, n_outputs)] The target values (class labels) as integers or strings.
**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- **ccp_path** [Bunch] Dictionary-like object, with attributes:
  - **ccp_alphas** [ndarray] Effective alphas of subtree during pruning.
  - **impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

- **decision_path** *(self, X, check_input=True)*
  Return the decision path in the tree.
  New in version 0.18.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **indicator** [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature_importances_**
Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

**Returns**

- **feature_importances_** [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).

**fit**(self, X, y, sample_weight=None, check_input=True, X_idx_sorted=None)
Build a decision tree classifier from the training set (X, y).

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
X_idx_sorted [array-like of shape (n_samples, n_features), default=None] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

self [DecisionTreeClassifier] Fitted estimator.

get_depth (self)
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

self.tree_.max_depth [int] The maximum depth of the tree.

get_n_leaves (self)
Return the number of leaves of the decision tree.

Returns

self.tree_.n_leaves [int] Number of leaves.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (self, X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

predict_log_proba (self, X)
Predict class log-probabilities of the input samples X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.
predict_proba

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs
> 1] The class log-probabilities of the input samples. The order of the classes corresponds
to that in the attribute classes_.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Intern-
ally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to
a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this
parameter unless you know what you do.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs
> 1] The class probabilities of the input samples. The order of the classes corresponds to
that in the attribute classes_.

score (self, X, y, sample_weight=None)

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params

set_params (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component of
a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.
class sklearn.tree.ExtraTreeRegressor(criterion='mse', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, min_impurity_decrease=0.0, min_impurity_split=None, max_leaf_nodes=None, ccp_alpha=0.0)

An extremely randomized tree regressor.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the max_features randomly selected features and the best split among those is chosen. When max_features is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the User Guide.

Parameters

criterion ["mse", "friedman_mse", "mae"], default="mse"] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion, and "mae" for the mean absolute error.

New in version 0.18: Mean Absolute Error (MAE) criterion.

splitter ["random", "best"], default="random"] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider min_samples_split as the minimum number.
- If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

min_samples_leaf [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider min_samples_leaf as the minimum number.
- If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.
**max_features** [int, float, {“auto”, “sqrt”, “log2”} or None, default=”auto”] The number of features to consider when looking for the best split:

- If int, then consider \( \text{max_features} \) features at each split.
- If float, then \( \text{max_features} \) is a fraction and \( \text{int}(\text{max_features} \times \text{n_features}) \) features are considered at each split.
- If “auto”, then \( \text{max_features} = \text{n_features} \).
- If “sqrt”, then \( \text{max_features} = \sqrt{\text{n_features}} \).
- If “log2”, then \( \text{max_features} = \log_2(\text{n_features}) \).
- If None, then \( \text{max_features} = \text{n_features} \).

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than \( \text{max_features} \) features.

**random_state** [int or RandomState, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity} \right)
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

\( N, N_t, N_{t,R} \) and \( N_{t,L} \) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: \( \text{min_impurity_split} \) has been deprecated in favor of \( \text{min_impurity_decrease} \) in 0.19. The default value of \( \text{min_impurity_split} \) will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use \( \text{min_impurity_decrease} \) instead.

**max_leaf_nodes** [int, default=None] Grow a tree with \( \text{max_leaf_nodes} \) in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than \( \text{ccp_alpha} \) will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**Attributes**

**max_features_** [int] The inferred value of max_features.

**n_features_** [int] The number of features when fit is performed.
n_outputs_  [int] The number of outputs when fit is performed.

tree_  [Tree] The underlying Tree object. Please refer to help(sklearn.tree._tree.
Tree) for attributes of Tree object and Understanding the decision tree structure for basic
usage of these attributes.

See also:

ExtraTreeClassifier An extremely randomized tree classifier.

Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth,
min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on
some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by
setting those parameter values.

Examples

```python
>>> from sklearn.datasets import load_boston
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.tree import ExtraTreeRegressor

>>> X, y = load_boston(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, random_state=0)
>>> extra_tree = ExtraTreeRegressor(random_state=0)
>>> reg = BaggingRegressor(extra_tree, random_state=0).fit(
...     X_train, y_train)
>>> reg.score(X_test, y_test)
0.7823...
```

Methods

apply(self, X[, check_input])  Return the index of the leaf that each sample is pre-
dicted as.

cost_complexity_pruning_path(self, X, y[, . . . ])
Cost complexity pruning path.
Table 302 – continued from previous page

**__init__**(self, criterion='mse', splitter='random', max_depth=None, min_samples_split=2,
min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto',
random_state=None, min_impurity_decrease=0.0, min_impurity_split=None,
max_leaf_nodes=None, ccp_alpha=0.0)

Initialize self. See help(type(self)) for accurate signature.

**apply**(self, X, check_input=True)

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

**Parameters**

- X : [array-like, sparse matrix] of shape (n_samples, n_features)
  The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- check_input : [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- X_leaves : [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

**cost_complexity_pruning_path**(self, X, y, sample_weight=None)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See **Minimal Cost-Complexity Pruning** for details on the pruning process.

**Parameters**

- X : [array-like, sparse matrix] of shape (n_samples, n_features)
  The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

- y : [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

- sample_weight : [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- ccp_path : [Bunch] Dictionary-like object, with attributes:
  - ccp_alphas : [ndarray] Effective alphas of subtree during pruning.
  - impurities : [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

**decision_path**(self, X, check_input=True)

Return the decision path in the tree.

7.37. **sklearn.tree**: Decision Trees
New in version 0.18.

Parameters

- X  
  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- check_input  
  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

- indicator  
  [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_
Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns

- feature_importances_  
  [ndarray of shape (n_features,)] Normalized total reduction of criterion by feature (Gini importance).

fit (self, X, y, sample_weight=None, check_input=True, X_idx_sorted=None)
Build a decision tree regressor from the training set (X, y).

Parameters

- X  
  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

- y  
  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (real numbers). Use dtype=np.float64 and order='C' for maximum efficiency.

- sample_weight  
  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

- check_input  
  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

- X_idx_sorted  
  [array-like of shape (n_samples, n_features), default=None] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

- self  
  [DecisionTreeRegressor] Fitted estimator.

get_depth (self)
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

- self.tree_.max_depth  
  [int] The maximum depth of the tree.
get_n_leaves (self)
Return the number of leaves of the decision tree.

Returns
self.tree_.n_leaves [int] Number of leaves.

get_params (self, deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.
predict (self, X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model,
the predicted value based on X is returned.

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Inter-

nally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to
a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this
parameter unless you know what you do.

Returns
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the
predict values.

score (self, X, y, sample_weight=None)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) **
2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score
is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always
predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may
be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,
n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for
the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] R^2 of self.predict(X) wrt. y.
Notes

The R² score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `r2_score`. This will influence the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `r2_score` directly or make a custom scorer with `make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

`set_params` (self, **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [object] Estimator instance.

```
tree.export_graphviz(decision_tree[...])  # Export a decision tree in DOT format.
tree.export_text(decision_tree[...])     # Build a text report showing the rules of a decision tree.
```

7.37.5 sklearn.tree.export_graphviz

`sklearn.tree.export_graphviz(decision_tree, out_file=None, max_depth=None, feature_names=None, class_names=None, label='all', filled=False, leaves_parallel=False, impurity=True, node_ids=False, proportion=False, rotate=False, rounded=False, special_characters=False, precision=3)`

Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into `out_file`. Once exported, graphical renderings can be generated using, for example:

```
$ dot -Tps tree.dot -o tree.ps  # (PostScript format)
$ dot -Tpng tree.dot -o tree.png # (PNG format)
```

The sample counts that are shown are weighted with any `sample_weights` that might be present.

Read more in the User Guide.

Parameters

`decision_tree` [decision tree classifier] The decision tree to be exported to GraphViz.

`out_file` [file object or string, optional (default=None)] Handle or name of the output file. If `None`, the result is returned as a string.

Changed in version 0.20: Default of `out_file` changed from “tree.dot” to `None`.

`max_depth` [int, optional (default=None)] The maximum depth of the representation. If `None`, the tree is fully generated.

`feature_names` [list of strings, optional (default=None)] Names of each of the features.
class_names [list of strings, bool or None, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.

label [‘all’, ‘root’, ‘none’], optional (default=’all’) Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.

filled [bool, optional (default=False)] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

leaves_parallel [bool, optional (default=False)] When set to True, draw all leaf nodes at the bottom of the tree.

impurity [bool, optional (default=True)] When set to True, show the impurity at each node.

node_ids [bool, optional (default=False)] When set to True, show the ID number on each node.

proportion [bool, optional (default=False)] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.

rotate [bool, optional (default=False)] When set to True, orient tree left to right rather than top-down.

rounded [bool, optional (default=False)] When set to True, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

special_characters [bool, optional (default=False)] When set to False, ignore special characters for PostScript compatibility.

precision [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

Returns
dot_data [string] String representation of the input tree in GraphViz dot format. Only returned if out_file is None.

New in version 0.18.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree

>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()

>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf)
'digraph Tree {...
```

7.37.6 sklearn.tree.export_text

sklearn.tree.export_text (decision_tree, feature_names=None, max_depth=10, spacing=3, decimals=2, show_weights=False)

Build a text report showing the rules of a decision tree.
Note that backwards compatibility may not be supported.

Parameters

- **decision_tree** [object] The decision tree estimator to be exported. It can be an instance of DecisionTreeClassifier or DecisionTreeRegressor.

- **feature_names** [list, optional (default=None)] A list of length n_features containing the feature names. If None generic names will be used (“feature_0”, “feature_1”, ...).

- **max_depth** [int, optional (default=10)] Only the first max_depth levels of the tree are exported. Truncated branches will be marked with “...”.

- **spacing** [int, optional (default=3)] Number of spaces between edges. The higher it is, the wider the result.

- **decimals** [int, optional (default=3)] Number of decimal digits to display.

- **show_weights** [bool, optional (default=False)] If true the classification weights will be exported on each leaf. The classification weights are the number of samples each class.

Returns

- **report** [string] Text summary of all the rules in the decision tree.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.tree import DecisionTreeClassifier
>>> from sklearn.tree import export_text
>>> iris = load_iris()
>>> X = iris['data']
>>> y = iris['target']
>>> decision_tree = DecisionTreeClassifier(random_state=0, max_depth=2)
>>> decision_tree = decision_tree.fit(X, y)
>>> r = export_text(decision_tree, feature_names=iris['feature_names'])
>>> print(r)
|--- petal width (cm) <= 0.80
 | |--- class: 0
 |--- petal width (cm) > 0.80
 | |--- petal width (cm) <= 1.75
 | | |--- class: 1
 | |--- petal width (cm) > 1.75
 | | |--- class: 2
```

7.37.7 Plotting

**tree.plot_tree**(decision_tree[, max_depth, ...])  Plot a decision tree.

```python
sklearn.tree.plot_tree
```

**sklearn.tree.plot_tree**(decision_tree, max_depth=None, feature_names=None, class_names=None, label='all', filled=False, impurity=True, node_ids=False, proportion=False, rotate=False, rounded=False, precision=3, ax=None, fontsize=None)

Plot a decision tree.
The sample counts that are shown are weighted with any sample_weights that might be present.
The visualization is fit automatically to the size of the axis. Use the figsize or dpi arguments of plt.figure to control the size of the rendering.
Read more in the User Guide.
New in version 0.21.

Parameters

decision_tree  [decision tree regressor or classifier] The decision tree to be plotted.

max_depth  [int, optional (default=None)] The maximum depth of the representation. If None, the tree is fully generated.

feature_names  [list of strings, optional (default=None)] Names of each of the features.

class_names  [list of strings, bool or None, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.

label  [‘all’, ‘root’, ‘none’], optional (default=’all’) Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.

filled  [bool, optional (default=False)] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

impurity  [bool, optional (default=True)] When set to True, show the impurity at each node.

node_ids  [bool, optional (default=False)] When set to True, show the ID number on each node.

proportion  [bool, optional (default=False)] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.

rotate  [bool, optional (default=False)] When set to True, orient tree left to right rather than top-down.

rounded  [bool, optional (default=False)] When set to True, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

precision  [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

ax  [matplotlib axis, optional (default=None)] Axes to plot to. If None, use current axis. Any previous content is cleared.

fontsize  [int, optional (default=None)] Size of text font. If None, determined automatically to fit figure.

Returns

annotations  [list of artists] List containing the artists for the annotation boxes making up the tree.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree
```
Examples using sklearn.tree.plot_tree

- Plot the decision surface of a decision tree on the iris dataset

7.38 sklearn.utils: Utilities

The sklearn.utils module includes various utilities.

Developer guide: See the Utilities for Developers page for further details.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>utils.arrayfuncs.min_pos()</td>
<td>Find the minimum value of an array over positive values</td>
</tr>
<tr>
<td>utils.as_float_array(X[, force_all_finite])</td>
<td>Converts an array-like to an array of floats.</td>
</tr>
<tr>
<td>utils.assert_all_finite(X[, allow_nan])</td>
<td>Throw a ValueError if X contains NaN or infinity.</td>
</tr>
<tr>
<td>utils.check_X_y(X, y[, accept_sparse, ...])</td>
<td>Input validation for standard estimators.</td>
</tr>
<tr>
<td>utils.check_array(array[, accept_sparse, ...])</td>

### 7.38.1 sklearn.utils.arrayfuncs.min_pos

`sklearn.utils.arrayfuncs.min_pos()`  
Find the minimum value of an array over positive values  
Returns a huge value if none of the values are positive
7.38.2 sklearn.utils.as_float_array

sklearn.utils.as_float_array(X, copy=True, force_all_finite=True)

Converts an array-like to an array of floats.

The new dtype will be np.float32 or np.float64, depending on the original type. The function can create a copy or modify the argument depending on the argument copy.

Parameters

- **X** ([array-like, sparse matrix])
- **copy** [bool, optional] If True, a copy of X will be created. If False, a copy may still be returned if X’s dtype is not a floating point type.
- **force_all_finite** [boolean or ‘allow-nan’, (default=True)] Whether to raise an error on np.inf and np.nan in X. The possibilities are:
  - True: Force all values of X to be finite.
  - False: accept both np.inf and np.nan in X.
  - ‘allow-nan’: accept only np.nan values in X. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.

Returns

- **XT** [{array, sparse matrix}] An array of type np.float

7.38.3 sklearn.utils.assert_all_finite

sklearn.utils.assert_all_finite(X, allow_nan=False)

Throw a ValueError if X contains NaN or infinity.

Parameters

- **X** [array or sparse matrix]
- **allow_nan** [bool]

7.38.4 sklearn.utils.check_X_y

sklearn.utils.check_X_y(X, y, accept_sparse=False, accept_large_sparse=True, dtype='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, multi_output=False, ensure_min_samples=1, ensure_min_features=1, y_numeric=False, warn_on_dtype=None, estimator=None)

Input validation for standard estimators.

Checks X and y for consistent length, enforces X to be 2D and y 1D. By default, X is checked to be non-empty and containing only finite values. Standard input checks are also applied to y, such as checking that y does not have np.nan or np.inf targets. For multi-label y, set multi_output=True to allow 2D and sparse y. If the dtype of X is object, attempt converting to float, raising on failure.

Parameters

- **X** [nd-array, list or sparse matrix] Input data.
- **y** [nd-array, list or sparse matrix] Labels.
accept_sparse  [string, boolean or list of string (default=False)] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

accept_large_sparse  [bool (default=True)] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept_sparse, accept_large_sparse will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

dtype  [string, type, list of types or None (default="numeric"))] Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order  ['F', 'C' or None (default=None)] Whether an array will be forced to be fortran or c-style.

copy  [boolean (default=False)] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite  [boolean or 'allow-nan', (default=True)] Whether to raise an error on np.inf and np.nan in X. This parameter does not influence whether y can have np.inf or np.nan values. The possibilities are:
- True: Force all values of X to be finite.
- False: accept both np.inf and np.nan in X.
- 'allow-nan': accept only np.nan values in X. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.

ensure_2d  [boolean (default=True)] Whether to raise a value error if X is not 2D.

allow_nd  [boolean (default=False)] Whether to allow X.ndim > 2.

multi_output  [boolean (default=False)] Whether to allow 2D y (array or sparse matrix). If false, y will be validated as a vector. y cannot have np.nan or np.inf values if multi_output=True.

ensure_min_samples  [int (default=1)] Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

ensure_min_features  [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.

y_numeric  [boolean (default=False)] Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to float64. Should only be used for regression algorithms.

warn_on_dtype  [boolean or None, optional (default=None)] Raise DataConversionWarning if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

Deprecated since version 0.21: warn_on_dtype is deprecated in version 0.21 and will be removed in 0.23.

estimator  [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

Returns
X_converted [object] The converted and validated X.

y_converted [object] The converted and validated y.

7.38.5 sklearn.utils.check_array

sklearn.utils.check_array(array, accept_sparse=False, accept_large_sparse=True, dtypes='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, ensure_min_samples=1, ensure_min_features=1, warn_on_dtype=None, estimator=None)

Input validation on an array, list, sparse matrix or similar.

By default, the input is checked to be a non-empty 2D array containing only finite values. If the dtype of the array is object, attempt converting to float, raising on failure.

Parameters

array [object] Input object to check / convert.

accept_sparse [string, boolean or list/tuple of strings (default=False)] String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

accept_large_sparse [bool (default=True)] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept_sparse, accept_large_sparse=False will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

dtype [string, type, list of types or None (default="numeric")] Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order ['F', 'C' or None (default=None)] Whether an array will be forced to be fortran or c-style. When order is None (default), then if copy=False, nothing is ensured about the memory layout of the output array; otherwise (copy=True) the memory layout of the returned array is kept as close as possible to the original array.

copy [boolean (default=False)] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite [boolean or ‘allow-nan’, (default=True)] Whether to raise an error on np.inf and np.nan in array. The possibilities are:

• True: Force all values of array to be finite.
• False: accept both np.inf and np.nan in array.
• ‘allow-nan’: accept only np.nan values in array. Values cannot be infinite.

For object dtyped data, only np.nan is checked and not np.inf.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.

ensure_2d [boolean (default=True)] Whether to raise a value error if array is not 2D.

allow_nd [boolean (default=False)] Whether to allow array.ndim > 2.

ensure_min_samples [int (default=1)] Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.
ensure_min_features [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input data has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.

warn_on_dtype [boolean or None, optional (default=None)] Raise DataConversionWarning if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

Deprecated since version 0.21: warn_on_dtype is deprecated in version 0.21 and will be removed in 0.23.

estimator [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

Returns

array_converted [object] The converted and validated array.

7.38.6 sklearn.utils.check_scalar

sklearn.utils.check_scalar (x, name, target_type, min_val=None, max_val=None)
Validate scalar parameters type and value.

Parameters

x [object] The scalar parameter to validate.

name [str] The name of the parameter to be printed in error messages.

target_type [type or tuple] Acceptable data types for the parameter.

min_val [float or int, optional (default=None)] The minimum valid value the parameter can take. If None (default) it is implied that the parameter does not have a lower bound.

max_val [float or int, optional (default=None)] The maximum valid value the parameter can take. If None (default) it is implied that the parameter does not have an upper bound.

Raises

TypeError If the parameter’s type does not match the desired type.

ValueError If the parameter’s value violates the given bounds.

7.38.7 sklearn.utils.check_consistent_length

sklearn.utils.check_consistent_length (*arrays)
Check that all arrays have consistent first dimensions.
Checks whether all objects in arrays have the same shape or length.

Parameters

*arrays [list or tuple of input objects.] Objects that will be checked for consistent length.

7.38.8 sklearn.utils.check_random_state

sklearn.utils.check_random_state (seed)
Turn seed into a np.random.RandomState instance
Parameters

  seed  [None l int l instance of RandomState] If seed is None, return the RandomState singleton used by np.random. If seed is an int, return a new RandomState instance seeded with seed. If seed is already a RandomState instance, return it. Otherwise raise ValueError.

Examples using sklearn.utils.check_random_state

- Isotonic Regression
- Face completion with a multi-output estimators
- Empirical evaluation of the impact of k-means initialization
- MNIST classification using multinomial logistic + L1
- Manifold Learning methods on a severed sphere
- Scaling the regularization parameter for SVCs

7.38.9 sklearn.utils.class_weight.compute_class_weight

sklearn.utils.class_weight.compute_class_weight(class_weight, classes, y)
Estimate class weights for unbalanced datasets.

Parameters

  class_weight  [dict, ‘balanced’ or None] If ‘balanced’, class weights will be given by \( \frac{n \_ samples}{(n \_ classes \times np \_ bincount(y))} \). If a dictionary is given, keys are classes and values are corresponding class weights. If None is given, the class weights will be uniform.

  classes  [ndarray] Array of the classes occurring in the data, as given by np.unique(y \_ org) with y \_ org the original class labels.

  y  [array-like, shape (n_samples,)] Array of original class labels per sample;

Returns

  class_weight_vect  [ndarray, shape (n_classes,)] Array with class_weight_vect[i] the weight for i-th class

References

The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

7.38.10 sklearn.utils.class_weight.compute_sample_weight

sklearn.utils.class_weight.compute_sample_weight(class_weight, y, indices=None)
Estimate sample weights by class for unbalanced datasets.

Parameters

  class_weight  [dict, list of dicts, “balanced”, or None, optional] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.
Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be 
\[
\{(0: 1, 1: 1), (0: 1, 1: 5), (0: 1, 1: 1), (0: 1, 1: 1)\}
\] instead of 
\[
\{(1:1), (2:5), (3:1), (4:1)\}.
\]

The “balanced” mode uses the values of \(y\) to automatically adjust weights inversely proportional to class frequencies in the input data: 
\[
\text{n_samples} / (\text{n_classes} * \text{np.bincount}(y)).
\]

For multi-output, the weights of each column of \(y\) will be multiplied.

\(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] Array of original class labels per sample.

\(\text{indices}\) [array-like, shape (n_subsample,), or None] Array of indices to be used in a subsample. Can be of length less than \(\text{n_samples}\) in the case of a subsample, or equal to \(\text{n_samples}\) in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only “balanced” is supported for class_weight if this is provided.

Returns

\(\text{sample_weight_vect}\) [ndarray, shape (n_samples,)] Array with sample weights as applied to the original \(y\)

### 7.38.11 sklearn.utils.deprecated

**sklearn.utils.deprecated**(extra="")

Decorator to mark a function or class as deprecated.

Issue a warning when the function is called/the class is instantiated and adds a warning to the docstring.

The optional extra argument will be appended to the deprecation message and the docstring. Note: to use this with the default value for extra, put in an empty of parentheses:

```python
>>> from sklearn.utils import deprecated
>>> deprecated()
<sklearn.utils.deprecation.deprecated object at ...>
```

```python
>>> @deprecated()  
... def some_function(): pass
```

**Parameters**

extra [string] to be added to the deprecation messages

### 7.38.12 sklearn.utils.estimator_checks.check_estimator

**sklearn.utils.estimator_checks.check_estimator**(Estimator, generate_only=False)

Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc. Additional tests for classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the corresponding mixin from sklearn.base.

This test can be applied to classes or instances. Classes currently have some additional tests that related to construction, while passing instances allows the testing of multiple options.
Read more in *Rolling your own estimator*.

**Parameters**

- **estimator** [estimator object or class] Estimator to check. Estimator is a class object or instance.
- **generate_only** [bool, optional (default=False)] When False, checks are evaluated when check_estimator is called. When True, check_estimator returns a generator that yields (estimator, check) tuples. The check is run by calling check(estimator).

New in version 0.22.

**Returns**

- **checks_generator** [generator] Generator that yields (estimator, check) tuples. Returned when generate_only=True.

### 7.38.13 sklearn.utils.estimator_checks.parametrize_with_checks

**sklearn.utils.estimator_checks.parametrize_with_checks(estimators)**

Pytest specific decorator for parametrizing estimator checks.

The id of each test is set to be a pprint version of the estimator and the name of the check with its keyword arguments.

Read more in the User Guide.

**Parameters**

- **estimators** [list of estimators objects or classes] Estimators to generated checks for.

**Returns**

- **decorator** [pytest.mark.parametrize]

**Examples using sklearn.utils.estimator_checks.parametrize_with_checks**

• *Release Highlights for scikit-learn 0.22*

### 7.38.14 sklearn.utils.extmath.safe_sparse_dot

**sklearn.utils.extmath.safe_sparse_dot(a, b, dense_output=False)**

Dot product that handle the sparse matrix case correctly

**Parameters**

- **a** [array or sparse matrix]
- **b** [array or sparse matrix]
- **dense_output** [boolean, (default=False)] When False, a and b both being sparse will yield sparse output. When True, output will always be a dense array.

**Returns**

- **dot_product** [array or sparse matrix] sparse if a and b are sparse and dense_output=False.
7.38.15 sklearn.utils.extmath.randomized_range_finder

sklearn.utils.extmath.randomized_range_finder(A, size, n_iter,
power_iteration_normalizer='auto',
random_state=None)

Computes an orthonormal matrix whose range approximates the range of A.

Parameters

- **A** [2D array] The input data matrix
- **size** [integer] Size of the return array
- **n_iter** [integer] Number of power iterations used to stabilize the result
- **power_iteration_normalizer** ['auto' (default), 'QR', 'LU', 'none'] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), 'none' (the fastest but numerically unstable when n_iter is large, e.g. typically 5 or larger), or 'LU' factorization (numerically stable but can lose slightly in accuracy). The 'auto' mode applies no normalization if n_iter <= 2 and switches to LU otherwise.

New in version 0.18.

- **random_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

- **Q** [2D array] A (size x size) projection matrix, the range of which approximates well the range of the input matrix A.

Notes

An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

7.38.16 sklearn.utils.extmath.randomized_svd

sklearn.utils.extmath.randomized_svd(M, n_components, n_oversamples=10, n_iter='auto',
power_iteration_normalizer='auto', transpose='auto',
flip_sign=True, random_state=0)

Computes a truncated randomized SVD

Parameters

- **M** [ndarray or sparse matrix] Matrix to decompose
- **n_components** [int] Number of singular values and vectors to extract.
- **n_oversamples** [int (default is 10)] Additional number of random vectors to sample the range of M so as to ensure proper conditioning. The total number of random vectors used to find the range of M is n_components + n_oversamples. Smaller number can improve speed but can negatively impact the quality of approximation of singular vectors and singular values.
n_iter [int or ‘auto’ (default is ‘auto’)] Number of power iterations. It can be used to deal with very noisy problems. When ‘auto’, it is set to 4, unless n_components is small (< .1 * min(X.shape)) n_iter in which case is set to 7. This improves precision with few components.

Changed in version 0.18.

power_iteration_normalizer ['auto' (default), ‘QR’, ‘LU’, ‘none’] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), ‘none’ (the fastest but numerically unstable when n_iter is large, e.g. typically 5 or larger), or ‘LU’ factorization (numerically stable but can lose slightly in accuracy). The ‘auto’ mode applies no normalization if n_iter <= 2 and switches to LU otherwise.

New in version 0.18.

transpose [True, False or ‘auto’ (default)] Whether the algorithm should be applied to M.T instead of M. The result should approximately be the same. The ‘auto’ mode will trigger the transposition if M.shape[1] > M.shape[0] since this implementation of randomized SVD tend to be a little faster in that case.

Changed in version 0.18.

flip_sign [boolean, (True by default)] The output of a singular value decomposition is only unique up to a permutation of the signs of the singular vectors. If flip_sign is set to True, the sign ambiguity is resolved by making the largest loadings for each component in the left singular vectors positive.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Notes

This algorithm finds a (usually very good) approximate truncated singular value decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components. In order to obtain further speed up, n_iter can be set <=2 (at the cost of loss of precision).

References

- A randomized algorithm for the decomposition of matrices Per-Gunnar Martinsson, Vladimir Rokhlin and Mark Tygert
- An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

7.38.17 sklearn.utils.extmath.fast_logdet

sklearn.utils.extmath.fast_logdet(A)
Compute log(det(A)) for A symmetric

Equivalent to : np.log(nl.det(A)) but more robust. It returns -Inf if det(A) is non positive or is not defined.
Parameters

A  [array_like] The matrix

7.38.18 sklearn.utils.extmath.density

sklearn.utils.extmath.density(w, **kwargs)
Compute density of a sparse vector

Parameters

w  [array_like] The sparse vector

Returns

float  The density of w, between 0 and 1

Examples using sklearn.utils.extmath.density

- Classification of text documents using sparse features

7.38.19 sklearn.utils.extmath.weighted_mode

sklearn.utils.extmath.weighted_mode(a, w, axis=0)
Returns an array of the weighted modal (most common) value in a
If there is more than one such value, only the first is returned. The bin-count for the modal bins is also returned.
This is an extension of the algorithm in scipy.stats.mode.

Parameters

a  [array_like] n-dimensional array of which to find mode(s).

w  [array_like] n-dimensional array of weights for each value

axis  [int, optional] Axis along which to operate. Default is 0, i.e. the first axis.

Returns

vals  [ndarray] Array of modal values.

score  [ndarray] Array of weighted counts for each mode.

See also:

scipy.stats.mode

Examples

```python
>>> from sklearn.utils.extmath import weighted_mode
>>> x = [4, 1, 4, 2, 4, 2]
>>> weights = [1, 1, 1, 1, 1, 1]
>>> weighted_mode(x, weights)
(array([4.]), array([3.]))
```

The value 4 appears three times: with uniform weights, the result is simply the mode of the distribution.
```python
>>> weights = [1, 3, 0.5, 1.5, 1, 2]  # deweight the 4's
>>> weighted_mode(x, weights)
(array([2]), array([3.5]))
```

The value 2 has the highest score: it appears twice with weights of 1.5 and 2: the sum of these is 3.5.

### 7.38.20 sklearn.utils.gen_even_slices

**sklearn.utils.gen_even_slices** *(n, n_packs, n_samples=None)*  
Generator to create *n_packs* slices going up to *n*.

**Parameters**

- **n** [int]
- **n_packs** [int] Number of slices to generate.
- **n_samples** [int or None (default = None)] Number of samples. Pass *n_samples* when the slices are to be used for sparse matrix indexing; slicing off-the-end raises an exception, while it works for NumPy arrays.

**Yields**

- slice

**Examples**

```python
>>> from sklearn.utils import gen_even_slices
>>> list(gen_even_slices(10, 1))
[slice(0, 10, None)]
>>> list(gen_even_slices(10, 10))
[slice(0, 1, None), slice(1, 2, None), ..., slice(9, 10, None)]
>>> list(gen_even_slices(10, 5))
[slice(0, 2, None), slice(2, 4, None), ..., slice(8, 10, None)]
>>> list(gen_even_slices(10, 3))
[slice(0, 4, None), slice(4, 7, None), slice(7, 10, None)]
```

### 7.38.21 sklearn.utils.graph.single_source_shortest_path_length

**sklearn.utils.graph.single_source_shortest_path_length** *(graph, source, cutoff=None)*  
Return the shortest path length from source to all reachable nodes.

Returns a dictionary of shortest path lengths keyed by target.

**Parameters**

- **graph** [sparse matrix or 2D array (preferably LIL matrix)] Adjacency matrix of the graph
- **source** [integer] Starting node for path
- **cutoff** [integer, optional] Depth to stop the search - only paths of length <= cutoff are returned.

Examples

```python
>>> from sklearn.utils.graph import single_source_shortest_path_length
>>> import numpy as np
>>> graph = np.array([[ 0, 1, 0, 0],
...                   [ 1, 0, 1, 0],
...                   [ 0, 1, 0, 1],
...                   [ 0, 0, 1, 0]])
>>> list(sorted(single_source_shortest_path_length(graph, 0).items()))
[(0, 0), (1, 1), (2, 2), (3, 3)]
>>> graph = np.ones((6, 6))
>>> list(sorted(single_source_shortest_path_length(graph, 2).items()))
[(0, 1), (1, 1), (2, 0), (3, 1), (4, 1), (5, 1)]
```

7.38.22 sklearn.utils.graph_shortest_path

**graph_shortest_path()**

Perform a shortest-path graph search on a positive directed or undirected graph.

**Parameters**

- **dist_matrix** [arraylike or sparse matrix, shape = (N,N)] Array of positive distances. If vertex i is connected to vertex j, then dist_matrix[i,j] gives the distance between the vertices. If vertex i is not connected to vertex j, then dist_matrix[i,j] = 0

- **directed** [boolean] if True, then find the shortest path on a directed graph: only progress from a point to its neighbors, not the other way around. if False, then find the shortest path on an undirected graph: the algorithm can progress from a point to its neighbors and vice versa.

- **method** [string ['auto'|'FW'|'D'] method to use. Options are ‘auto’: attempt to choose the best method for the current problem ‘FW’: Floyd-Warshall algorithm. O[N^3] ‘D’: Dijkstra’s algorithm with Fibonacci stacks. O[(k+log(N))N^2]

**Returns**

- **G** [np.ndarray, float, shape = [N,N]] G[i,j] gives the shortest distance from point i to point j along the graph.

**Notes**

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if dist_matrix[i,j] and dist_matrix[j,i] are not equal and both are nonzero, method='D' will not necessarily yield the correct result.

Also, these routines have not been tested for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms.

7.38.23 sklearn.utils.indexable

**indexable(*iterables)**

Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-interable objects to arrays.

**Parameters**
*iterables* [lists, dataframes, arrays, sparse matrices] List of objects to ensure sliceability.

## 7.38.24 sklearn.utils.metaestimators.if_delegate_has_method

**sklearn.utils.metaestimators.if_delegate_has_method**(delegate)

Create a decorator for methods that are delegated to a sub-estimator

This enables ducktyping by hasattr returning True according to the sub-estimator.

**Parameters**

- **delegate** [string, list of strings or tuple of strings] Name of the sub-estimator that can be accessed as an attribute of the base object. If a list or a tuple of names are provided, the first sub-estimator that is an attribute of the base object will be used.

**Examples using sklearn.utils.metaestimators.if_delegate_has_method**

- **Inductive Clustering**

## 7.38.25 sklearn.utils.multiclass.type_of_target

**sklearn.utils.multiclass.type_of_target**(y)

Determine the type of data indicated by the target.

Note that this type is the most specific type that can be inferred. For example:

- **binary** is more specific but compatible with **multiclass**.
- **multiclass** of integers is more specific but compatible with **continuous**.
- **multilabel-indicator** is more specific but compatible with **multiclass-multioutput**.

**Parameters**

- **y** [array-like]

**Returns**

- **target_type** [string] One of:
  - **continuous**: y is an array-like of floats that are not all integers, and is 1d or a column vector.
  - **continuous-multioutput**: y is a 2d array of floats that are not all integers, and both dimensions are of size > 1.
  - **binary**: y contains <= 2 discrete values and is 1d or a column vector.
  - **multiclass**: y contains more than two discrete values, is not a sequence of sequences, and is 1d or a column vector.
  - **multiclass-multioutput**: y is a 2d array that contains more than two discrete values, is not a sequence of sequences, and both dimensions are of size > 1.
  - **multilabel-indicator**: y is a label indicator matrix, an array of two dimensions with at least two columns, and at most 2 unique values.
  - **unknown**: y is array-like but none of the above, such as a 3d array, sequence of sequences, or an array of non-sequence objects.
Examples

```python
>>> import numpy as np
>>> type_of_target([0.1, 0.6])
'continuous'
>>> type_of_target([1, -1, -1, 1])
'binary'
>>> type_of_target(['a', 'b', 'a'])
'binary'
>>> type_of_target([1.0, 2.0])
'binary'
>>> type_of_target([1, 0, 2])
'multiclass'
>>> type_of_target([1.0, 0.0, 3.0])
'multiclass'
>>> type_of_target(['a', 'b', 'c'])
'multiclass'
>>> type_of_target(np.array([[1, 2], [3, 1]]))
'multiclass-multioutput'
>>> type_of_target([[1, 2]])
'multilabel-indicator'
>>> type_of_target(np.array([[1.5, 2.0], [3.0, 1.6]]))
'continuous-multioutput'
>>> type_of_target(np.array([[0, 1], [1, 1]]))
'multilabel-indicator'
```

### 7.38.26 sklearn.utils.multiclass.is_multilabel

**sklearn.utils.multiclass.is_multilabel(y)**

Check if y is in a multilabel format.

**Parameters**

- y [numpy array of shape [n_samples]] Target values.

**Returns**

- out [bool] Return True, if y is in a multilabel format, else `False`.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.utils.multiclass import is_multilabel
>>> is_multilabel([0, 1, 0, 1])
False
>>> is_multilabel([[1], [0, 2], []])
False
>>> is_multilabel(np.array([[1, 0], [0, 0]]))
True
>>> is_multilabel(np.array([[1], [0], [0]]))
False
>>> is_multilabel(np.array([[1, 0, 0]]))
True
```
7.38.27 sklearn.utils.multiclass.unique_labels

sklearn.utils.multiclass.unique_labels(*ys)
Extract an ordered array of unique labels

We don't allow:

- mix of multilabel and multiclass (single label) targets
- mix of label indicator matrix and anything else, because there are no explicit labels
- mix of label indicator matrices of different sizes
- mix of string and integer labels

At the moment, we also don't allow “multiclass-multioutput” input type.

Parameters

*ys [array-likes]

Returns

out [numpy array of shape [n_unique_labels]] An ordered array of unique labels.

Examples

```python
>>> from sklearn.utils.multiclass import unique_labels
>>> unique_labels([3, 5, 5, 5, 7, 7])
array([3, 5, 7])
>>> unique_labels([1, 2, 3, 4], [2, 2, 3, 4])
array([1, 2, 3, 4])
>>> unique_labels([1, 2, 10], [5, 11])
array([ 1,  2,  5, 10, 11])
```

7.38.28 sklearn.utils.murmurhash3_32

sklearn.utils.murmurhash3_32()
Compute the 32bit murmurhash3 of key at seed.

The underlying implementation is MurmurHash3_x86_32 generating low latency 32bits hash suitable for implementating lookup tables, Bloom filters, count min sketch or feature hashing.

Parameters

key [int32, bytes, unicode or ndarray with dtype int32] the physical object to hash
seed [int, optional default is 0] integer seed for the hashing algorithm.
positive [boolean, optional default is False]

True: the results is casted to an unsigned int from 0 to 2 ** 32 - 1
False: the results is casted to a signed int from -(2 ** 31) to 2 ** 31 - 1

7.38.29 sklearn.utils.resample

sklearn.utils.resample(*arrays, **options)
Resample arrays or sparse matrices in a consistent way
The default strategy implements one step of the bootstrapping procedure.

Parameters

*arrays* [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

Returns

resampled_arrays [sequence of indexable data-structures] Sequence of resampled copies of the collections. The original arrays are not impacted.

Other Parameters

replace [boolean, True by default] Implements resampling with replacement. If False, this will implement (sliced) random permutations.

n_samples [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. If replace is False it should not be larger than the length of arrays.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

stratify [array-like or None (default=None)] If not None, data is split in a stratified fashion, using this as the class labels.

See also:

sklearn.utils.shuffle

Examples

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import resample

>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)

>>> X
array([[1., 0.],
       [2., 1.],
       [1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
with 4 stored elements in Compressed Sparse Row format

>>> X_sparse.toarray()
aarray([[1., 0.],
        [2., 1.],
        [1., 0.]])
```

(continues on next page)
Example using stratification:

```python
>>> y = [0, 0, 1, 1, 1, 1, 1, 1, 1]
>>> resample(y, n_samples=5, replace=False, stratify=y,
...          random_state=0)
[1, 1, 1, 0, 1]
```

### 7.38.30 sklearn.utils._safe_indexing

`sklearn.utils._safe_indexing` is a utility documented, but private. This means that backward compatibility might be broken without any deprecation cycle.

**Warning:** This utility is documented, but private. This means that backward compatibility might be broken without any deprecation cycle.

**Parameters**

- **X** [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series] Data from which to sample rows, items or columns. list are only supported when axis=0.

- **indices** [bool, int, str, slice, array-like]
  - If `axis=0`, boolean and integer array-like, integer slice, and scalar integer are supported.
  - If `axis=1`:
    - to select a single column, `indices` can be of *int* type for all *X* types and *str* only for dataframe. The selected subset will be 1D, unless *X* is a sparse matrix in which case it will be 2D.
    - to select multiples columns, `indices` can be one of the following: list, array, slice. The type used in these containers can be one of the following: int, ‘bool’ and str. However, str is only supported when *X* is a dataframe. The selected subset will be 2D.

- **axis** [int, default=0] The axis along which *X* will be subsampled. `axis=0` will select rows while `axis=1` will select columns.

**Returns**

- subset Subset of *X* on axis 0 or 1.

**Notes**

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.
**7.38.31 sklearn.utils.safe_mask**

```python
sklearn.utils.safe_mask(X, mask)
```
Return a mask which is safe to use on X.

**Parameters**
- `X` [array-like, sparse matrix] Data on which to apply mask.
- `mask` [array] Mask to be used on X.

**Returns**
- `mask`

**7.38.32 sklearn.utils.safe_sqr**

```python
sklearn.utils.safe_sqr(X, copy=True)
```
Element wise squaring of array-likes and sparse matrices.

**Parameters**
- `X` [array like, matrix, sparse matrix]
- `copy` [boolean, optional, default True] Whether to create a copy of X and operate on it or to perform inplace computation (default behaviour).

**Returns**
- `X ** 2` [element wise square]

**7.38.33 sklearn.utils.shuffle**

```python
sklearn.utils.shuffle(*arrays, **options)
```
Shuffle arrays or sparse matrices in a consistent way.

This is a convenience alias to `resample(*arrays, replace=False)` to do random permutations of the collections.

**Parameters**
- `*arrays` [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

**Returns**
- `shuffled_arrays` [sequence of indexable data-structures] Sequence of shuffled copies of the collections. The original arrays are not impacted.

**Other Parameters**
- `random_state` [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

- `n_samples` [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays.

See also:
**Examples**

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import shuffle

>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)
>>> X
array([[0., 0.],
       [2., 1.],
       [1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
with 3 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[0., 0.],
       [2., 1.],
       [1., 0.]])

>>> y
array([2, 1, 0])

>>> shuffle(y, n_samples=2, random_state=0)
array([0, 1])
```

**Examples using `sklearn.utils.shuffle`**

- Approximate nearest neighbors in TSNE

**7.38.34 sklearn.utils.sparsefuncs.incr_mean_variance_axis**

`sklearn.utils.sparsefuncs.incr_mean_variance_axis`(X, axis, last_mean, last_var, last_n)

Compute incremental mean and variance along an axis on a CSR or CSC matrix.

last_mean, last_var are the statistics computed at the last step by this function. Both must be initialized to 0-arrays of the proper size, i.e. the number of features in X. last_n is the number of samples encountered until now.

**Parameters**

- **X** [CSR or CSC sparse matrix, shape (n_samples, n_features)] Input data.
- **axis** [int (either 0 or 1)] Axis along which the axis should be computed.
- **last_mean** [float array with shape (n_features,)] Array of feature-wise means to update with the new data X.
last_var  [float array with shape (n_features,)] Array of feature-wise var to update with the new data X.

last_n  [int with shape (n_features,)] Number of samples seen so far, excluded X.

Returns

means  [float array with shape (n_features,)] Updated feature-wise means.

variances  [float array with shape (n_features,)] Updated feature-wise variances.

n  [int with shape (n_features,)] Updated number of seen samples.

Notes

NaNs are ignored in the algorithm.

7.38.35 sklearn.utils.sparsefuncs.inplace_column_scale

sklearn.utils.sparsefuncs.inplace_column_scale(X, scale)

Inplace column scaling of a CSC/CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters

X  [CSC or CSR matrix with shape (n_samples, n_features)] Matrix to normalize using the variance of the features.

scale  [float array with shape (n_features,)] Array of precomputed feature-wise values to use for scaling.

7.38.36 sklearn.utils.sparsefuncs.inplace_row_scale

sklearn.utils.sparsefuncs.inplace_row_scale(X, scale)

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters

X  [CSR or CSC sparse matrix, shape (n_samples, n_features)] Matrix to be scaled.

scale  [float array with shape (n_features,)] Array of precomputed sample-wise values to use for scaling.

7.38.37 sklearn.utils.sparsefuncs.inplace_swap_row

sklearn.utils.sparsefuncs.inplace_swap_row(X, m, n)

Swaps two rows of a CSC/CSR matrix in-place.

Parameters

X  [CSR or CSC sparse matrix, shape=(n_samples, n_features)] Matrix whose two rows are to be swapped.

m  [int] Index of the row of X to be swapped.
n  [int] Index of the row of X to be swapped.

7.38.38 sklearn.utils.sparsefuncs.inplace_swap_column

sklearn.utils.sparsefuncs.inplace_swap_column(X, m, n)
Swaps two columns of a CSC/CSR matrix in-place.

Parameters:
X  [CSR or CSC sparse matrix, shape=(n_samples, n_features)] Matrix whose two columns are to be swapped.

m  [int] Index of the column of X to be swapped.

n  [int] Index of the column of X to be swapped.

7.38.39 sklearn.utils.sparsefuncs.mean_variance_axis

sklearn.utils.sparsefuncs.mean_variance_axis(X, axis)
Compute mean and variance along an axis on a CSR or CSC matrix

Parameters:
X  [CSR or CSC sparse matrix, shape (n_samples, n_features)] Input data.

axis  [int (either 0 or 1)] Axis along which the axis should be computed.

Returns:
means  [float array with shape (n_features,)] Feature-wise means

variances  [float array with shape (n_features,)] Feature-wise variances

7.38.40 sklearn.utils.sparsefuncs.inplace_csr_column_scale

sklearn.utils.sparsefuncs.inplace_csr_column_scale(X, scale)
Inplace column scaling of a CSR matrix.
Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters:
X  [CSR matrix with shape (n_samples, n_features)] Matrix to normalize using the variance of the features.

scale  [float array with shape (n_features,)] Array of precomputed feature-wise values to use for scaling.

7.38.41 sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1

sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1()
Inplace row normalize using the l1 norm
7.38.42 sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2

```
sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2()
```

Inplace row normalize using the l2 norm

7.38.43 sklearn.utils.random.sample_without Replacement

```
sklearn.utils.random.sample_without_replacement()
```

Sample integers without replacement.

Select n_samples integers from the set [0, n_population) without replacement.

**Parameters**

- **n_population** [int] The size of the set to sample from.
- **n_samples** [int] The number of integer to sample.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **method** ["auto", "tracking_selection", "reservoir_sampling" or "pool"] If method == “auto”, the ratio of n_samples / n_population is used to determine which algorithm to use: If ratio is between 0 and 0.01, tracking selection is used. If ratio is between 0.01 and 0.99, numpy.random.permutation is used. If ratio is greater than 0.99, reservoir sampling is used. The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method =="tracking_selection", a set based implementation is used which is suitable for n_samples << n_population.

If method == "reservoir_sampling", a reservoir sampling algorithm is used which is suitable for high memory constraint or when O(n_samples) ~ O(n_population). The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method == "pool", a pool based algorithm is particularly fast, even faster than the tracking selection method. However, a vector containing the entire population has to be initialized. If n_samples ~ n_population, the reservoir sampling method is faster.

**Returns**

- **out** [array of size (n_samples, )] The sampled subsets of integer. The subset of selected integer might not be randomized, see the method argument.

7.38.44 sklearn.utils.validation.check_is_fitted

```
sklearn.utils.validation.check_is_fitted(estimator, attributes=None, msg=None, all_or_any=<built-in function all>)
```

Perform is_fitted validation for estimator.

Checks if the estimator is fitted by verifying the presence of fitted attributes (ending with a trailing underscore) and otherwise raises a NotFittedError with the given message.

This utility is meant to be used internally by estimators themselves, typically in their own predict / transform methods.
Parameters

estimator [estimator instance.] estimator instance for which the check is performed.

attributes [str, list or tuple of str, default=None] Attribute name(s) given as string or a list/tuple of strings Eg: ["coef_", "estimator_", ...], "coef_"

If None, estimator is considered fitted if there exist an attribute that ends with a underscore and does not start with double underscore.

msg [string] The default error message is, “This %(name)s instance is not fitted yet. Call ‘fit’ with appropriate arguments before using this estimator.”

For custom messages if “%(name)s” is present in the message string, it is substituted for the estimator name.

Eg.: “Estimator, %(name)s, must be fitted before sparsifying”.

all_or_any [callable, {all, any}, default all] Specify whether all or any of the given attributes must exist.

Returns

None

Raises

NotFittedError If the attributes are not found.

7.38.45 sklearn.utils.validation.check_memory

sklearn.utils.validation.check_memory (memory)

Check that memory is joblib.Memory-like.

joblib.Memory-like means that memory can be converted into a joblib.Memory instance (typically a str denoting the location) or has the same interface (has a cache method).

Parameters

memory [None, str or object with the joblib.Memory interface]

Returns

memory [object with the joblib.Memory interface]

Raises

ValueError If memory is not joblib.Memory-like.

7.38.46 sklearn.utils.validation.check_symmetric

sklearn.utils.validation.check_symmetric (array, tol=1e-10, raise_warning=True, raise_exception=False)

Make sure that array is 2D, square and symmetric.

If the array is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

Parameters

array [nd-array or sparse matrix] Input object to check / convert. Must be two-dimensional and square, otherwise a ValueError will be raised.
**tol** [float] Absolute tolerance for equivalence of arrays. Default = 1E-10.

**raise_warning** [boolean (default=True)] If True then raise a warning if conversion is required.

**raise_exception** [boolean (default=False)] If True then raise an exception if array is not symmetric.

**Returns**

**array_sym** [ndarray or sparse matrix] Symmetrized version of the input array, i.e. the average of array and array.transpose(). If sparse, then duplicate entries are first summed and zeros are eliminated.

### 7.38.47 sklearn.utils.validation.column_or_1d

sklearn.utils.validation.column_or_1d(y, warn=False)

Ravel column or 1d numpy array, else raises an error

**Parameters**

- **y** [array-like]
- **warn** [boolean, default False] To control display of warnings.

**Returns**

- **y** [array]

### 7.38.48 sklearn.utils.validation.has_fit_parameter

sklearn.utils.validation.has_fit_parameter(estimator, parameter)

Checks whether the estimator’s fit method supports the given parameter.

**Parameters**

- **estimator** [object] An estimator to inspect.
- **parameter** [str] The searched parameter.

**Returns**

**is_parameter** [bool] Whether the parameter was found to be a named parameter of the estimator’s fit method.

**Examples**

```python
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```

### 7.38.49 sklearn.utils.all_estimators

sklearn.utils.all_estimators(include_meta_estimators=None, include_other=None, type_filter=None, include_dont_test=None)

Get a list of all estimators from sklearn.

This function crawls the module and gets all classes that inherit from BaseEstimator. Classes that are defined in test-modules are not included. By default meta_estimators such as GridSearchCV are also not included.
Parameters

- **include_meta_estimators** [boolean, default=False] Deprecated, ignored.
  
  Deprecated since version 0.21: `include_meta_estimators` has been deprecated and has no effect in 0.21 and will be removed in 0.23.

- **include_other** [boolean, default=False] Deprecated, ignored.
  
  Deprecated since version 0.21: `include_other` has been deprecated and has no effect in 0.21 and will be removed in 0.23.

- **type_filter** [string, list of string, or None, default=None] Which kind of estimators should be returned. If None, no filter is applied and all estimators are returned. Possible values are ‘classifier’, ‘regressor’, ‘cluster’ and ‘transformer’ to get estimators only of these specific types, or a list of these to get the estimators that fit at least one of the types.

- **include_dont_test** [boolean, default=False] Deprecated, ignored.
  
  Deprecated since version 0.21: `include_dont_test` has been deprecated and has no effect in 0.21 and will be removed in 0.23.

Returns

- **estimators** [list of tuples] List of (name, class), where name is the class name as string and class is the actual type of the class.

Utilities from joblib:

```python
utils.parallel_backend(backend[, n_jobs, ...])
```

Change the default backend used by Parallel inside a with block.

```python
utils.register_parallel_backend(name, factory)
```

Register a new Parallel backend factory.

### 7.38.50 sklearn.utils.parallel_backend

**sklearn.utils.parallel_backend** *(backend, n_jobs=-1, inner_max_num_threads=None, **backend_params)*

Change the default backend used by Parallel inside a with block.

If `backend` is a string it must match a previously registered implementation using the `register_parallel_backend` function.

By default the following backends are available:

- ‘loky’: single-host, process-based parallelism (used by default),
- ‘threading’: single-host, thread-based parallelism,
- ‘multiprocessing’: legacy single-host, process-based parallelism.

‘loky’ is recommended to run functions that manipulate Python objects. ‘threading’ is a low-overhead alternative that is most efficient for functions that release the Global Interpreter Lock: e.g. I/O-bound code or CPU-bound code in a few calls to native code that explicitly releases the GIL.

In addition, if the *dask* and *distributed* Python packages are installed, it is possible to use the ‘dask’ backend for better scheduling of nested parallel calls without over-subscription and potentially distribute parallel calls over a networked cluster of several hosts.

Alternatively the backend can be passed directly as an instance.
By default all available workers will be used (n_jobs=-1) unless the caller passes an explicit value for the n_jobs parameter.

This is an alternative to passing a backend='backend_name' argument to the Parallel class constructor. It is particularly useful when calling into library code that uses joblib internally but does not expose the backend argument in its own API.

```python
>>> from operator import neg
>>> with parallel_backend('threading'):
...    print(Parallel()(delayed(neg)(i + 1) for i in range(5)))
... [-1, -2, -3, -4, -5]
```

Warning: this function is experimental and subject to change in a future version of joblib.

Joblib also tries to limit the oversubscription by limiting the number of threads usable in some third-party library threadpools like OpenBLAS, MKL or OpenMP. The default limit in each worker is set to \( \max(\text{cpu_count}() // \text{effective_n_jobs}, 1) \) but this limit can be overwritten with the inner_max_num_threads argument which will be used to set this limit in the child processes.

New in version 0.10.

### 7.38.51 sklearn.utils.register_parallel_backend

`sklearn.utils.register_parallel_backend(name, factory, make_default=False)`

Register a new Parallel backend factory.

- The new backend can then be selected by passing its name as the backend argument to the Parallel class. Moreover, the default backend can be overwritten globally by setting make_default=True.
- The factory can be any callable that takes no argument and return an instance of `ParallelBackendBase`.
- Warning: this function is experimental and subject to change in a future version of joblib.

New in version 0.10.

### 7.39 Recently deprecated

#### 7.39.1 To be removed in 0.23

```python
utils.Memory(**kwargs)
```

**Attributes**

```python
utils.Parallel(**kwargs)
```

**Methods**
sklearn.utils.Memory

**Warning:** DEPRECATED

```python
class sklearn.utils.Memory(**kwargs)

Attributes
- cachedir

Methods

- `cache(self[, func, ignore, verbose, mmap_mode])`
  Decorates the given function `func` to only compute its return value for input arguments not cached on disk.

- `clear(self[, warn])`
  Erase the complete cache directory.

- `eval(self, func, *args, **kwargs)`
  Eval function `func` with arguments `*args` and `**kwargs`, in the context of the memory.

- `format(self, obj[, indent])`
  Return the formatted representation of the object.

- `reduce_size(self)`
  Remove cache elements to make cache size fit in `bytes_limit`.

___

- `__init__(*args, **kwargs)`
  DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: pip install joblib.

- `cache(self, func=None, ignore=None, verbose=None, mmap_mode=False)`
  Decorates the given function `func` to only compute its return value for input arguments not cached on disk.

  **Parameters**

  - `func`: callable, optional
    The function to be decorated

  - `ignore`: list of strings
    A list of arguments name to ignore in the hashing

  - `verbose`: integer, optional
    The verbosity mode of the function. By default that of the memory object is used.

  - `mmap_mode`: {None, ‘r+’, ‘r’, ‘w+’, ‘c’}, optional
    The memmapping mode used when loading from cache numpy arrays. See numpy.load for the meaning of the arguments. By default that of the memory object is used.

  **Returns**

  - `decorated_func`: MemorizedFunc object
    The returned object is a MemorizedFunc object, that is callable (behaves like a function), but offers extra methods for cache lookup and management. See the documentation for joblib.memory.MemorizedFunc.

- `clear(self, warn=True)`
  Erase the complete cache directory.
```
**eval** *(self, func, *args, **kwargs)*

Eval function `func` with arguments `*args` and `**kwargs`, in the context of the memory.

This method works similarly to the builtin `apply`, except that the function is called only if the cache is not up to date.

**format** *(self, obj, indent=0)*

Return the formatted representation of the object.

**reduce_size** *(self)*

Remove cache elements to make cache size fit in `bytes_limit`.

---

**sklearn.utils.Parallel**

---

**Warning:** DEPRECATED

---

**class** `sklearn.utils.Parallel(**kwargs)`

---

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>call</strong></td>
<td>Call self as a function.</td>
</tr>
<tr>
<td>dispatch_next</td>
<td>Dispatch more data for parallel processing</td>
</tr>
<tr>
<td>dispatch_one_batch</td>
<td>Prefetch the tasks for the next batch and dispatch them.</td>
</tr>
<tr>
<td>format</td>
<td>Return the formatted representation of the object.</td>
</tr>
<tr>
<td>print_progress</td>
<td>Display the process of the parallel execution only a fraction of time, controlled by self.verbose.</td>
</tr>
</tbody>
</table>

---

**__init__** *(*args, **kwargs)*

DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: pip install joblib.

**dispatch_next** *(self)*

Dispatch more data for parallel processing

This method is meant to be called concurrently by the multiprocessing callback. We rely on the thread-safety of `dispatch_one_batch` to protect against concurrent consumption of the unprotected iterator.

**dispatch_one_batch** *(self, iterator)*

Prefetch the tasks for the next batch and dispatch them.

The effective size of the batch is computed here. If there are no more jobs to dispatch, return False, else return True.

The iterator consumption and dispatching is protected by the same lock so calling this function should be thread safe.

**format** *(self, obj, indent=0)*

Return the formatted representation of the object.
print_progress(self)
   Display the process of the parallel execution only a fraction of time, controlled by self.verbose.

utils.cpu_count()
   DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23.

utils.delayed(function[, check_pickle])
   DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23.

metrics.calinski_harabaz_score(X, labels)
   DEPRECATED: Function `calinski_harabaz_score` has been renamed to `calinski_harabasz_score` and will be removed in version 0.23.

metrics.jaccard_similarity_score(y_true, y_pred)
   Jaccard similarity coefficient score

linear_model.logistic_regression_path(X, y)
   DEPRECATED: logistic_regression_path was deprecated in version 0.21 and will be removed in version 0.23.0

utils.safe_indexing(X, indices[, axis])
   DEPRECATED: safe_indexing is deprecated in version 0.22 and will be removed in version 0.24.

sklearn.utils.cpu_count

Warning: DEPRECATED

sklearn.utils.cpu_count()
   DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: pip install joblib.

   Return the number of CPUs.

sklearn.utils.delayed

Warning: DEPRECATED

sklearn.utils.delayed(function, check_pickle=None)
   DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: pip install joblib.

   Decorator used to capture the arguments of a function.

sklearn.metrics.calinski_harabaz_score

Warning: DEPRECATED

sklearn.metrics.calinski_harabaz_score(X, labels)
   DEPRECATED: Function `calinski_harabaz_score` has been renamed to `calinski_harabasz_score` and will be removed in version 0.23.
sklearn.metrics.jaccard_similarity_score

**Warning:** DEPRECATED

sklearn.metrics.jaccard_similarity_score(y_true, y_pred, normalize=True, sample_weight=None)

Jaccard similarity coefficient score

Deprecated since version 0.21: This is deprecated to be removed in 0.23, since its handling of binary and multiclass inputs was broken. jaccard_score has an API that is consistent with precision_score, f_score, etc.

Read more in the User Guide.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **normalize** [bool, optional (default=True)] If False, return the sum of the Jaccard similarity coefficient over the sample set. Otherwise, return the average of Jaccard similarity coefficient.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] If normalize == True, return the average Jaccard similarity coefficient, else it returns the sum of the Jaccard similarity coefficient over the sample set.

The best performance is 1 with normalize == True and the number of samples with normalize == False.

See also:

accuracy_score, hamming_loss, zero_one_loss

**Notes**

In binary and multiclass classification, this function is equivalent to the accuracy_score. It differs in the multilabel classification problem.

**References**

[1]

sklearn.linear_model.logistic_regression_path

**Warning:** DEPRECATED
Compute a Logistic Regression model for a list of regularization parameters.

This is an implementation that uses the result of the previous model to speed up computations along the set of solutions, making it faster than sequentially calling LogisticRegression for the different parameters. Note that there will be no speedup with liblinear solver, since it does not handle warm-starting.

Deprecated since version 0.21: `logistic_regression_path` was deprecated in version 0.21 and will be removed in version 0.23.

Read more in the User Guide.

Parameters

- **X** [array-like or sparse matrix, shape (n_samples, n_features)]
  Input data.

- **y** [array-like, shape (n_samples,) or (n_samples, n_targets)] Input data, target values.

- **pos_class** [int, None] The class with respect to which we perform a one-vs-all fit. If None, then it is assumed that the given problem is binary.

- **Cs** [int | array-like, shape (n_cs,)] List of values for the regularization parameter or integer specifying the number of regularization parameters that should be used. In this case, the parameters will be chosen in a logarithmic scale between 1e-4 and 1e4.

- **fit_intercept** [bool] Whether to fit an intercept for the model. In this case the shape of the returned array is (n_cs, n_features + 1).

- **max_iter** [int] Maximum number of iterations for the solver.

- **tol** [float] Stopping criterion. For the newton-cg and lbfgs solvers, the iteration will stop when \( \max |g_i|_i = 1, \ldots, n \leq \text{tol} \) where \( g_i \) is the i-th component of the gradient.

- **verbose** [int] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

- **solver** [{'lbfgs', 'newton-cg', 'liblinear', 'sag', 'saga'}] Numerical solver to use.

- **coef** [array-like, shape (n_features,), default None] Initialization value for coefficients of logistic regression. Useless for liblinear solver.

- **class_weight** [dict or ‘balanced’, optional] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

  The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as \( n_{samples} / (n_{classes} \times \text{np.bincount}(y)) \).
Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**dual** [bool] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

**penalty** [str, ‘l1’, ‘l2’, or ‘elasticnet’] Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only l2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver.

**intercept_scaling** [float, default 1.] Useful only when the solver ‘liblinear’ is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

**multi_class** [‘ovr’, ‘multinomial’, ‘auto’], default=’auto’] If the option chosen is ‘ovr’, then a binary problem is fit for each label. For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution, even when the data is binary. ‘multinomial’ is unavailable when solver=’liblinear’. ‘auto’ selects ‘ovr’ if the data is binary, or if solver=’liblinear’, and otherwise selects ‘multinomial’.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.

Changed in version 0.22: Default changed from ‘ovr’ to ‘auto’ in 0.22.

**random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘sag’ or ‘liblinear’.

**check_input** [bool, default True] If False, the input arrays X and y will not be checked.

**max_squared_sum** [float, default None] Maximum squared sum of X over samples. Used only in SAG solver. If None, it will be computed, going through all the samples. The value should be precomputed to speed up cross validation.

**sample_weight** [array-like, shape(n_samples,) optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**l1_ratio** [float or None, optional (default=None)] The Elastic-Net mixing parameter, with 0 <= l1_ratio <= 1. Only used if penalty=’elasticnet’. Setting l1_ratio=0 is equivalent to using penalty=’l2’, while setting l1_ratio=1 is equivalent to using penalty=’l1’. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

**Returns**

**coefs** [ndarray, shape (n_cs, n_features) or (n_cs, n_features + 1)]

List of coefficients for the Logistic Regression model. If fit_intercept is set to True then the second dimension will be n_features + 1, where the last item represents the intercept. For multinomial=’multinomial’, the shape is (n_classes, n_cs, n_features) or (n_classes, n_cs, n_features + 1).

**Cs** [ndarray] Grid of Cs used for cross-validation.

7.39. Recently deprecated
**n_iter**  [array, shape (n_cs,)] Actual number of iteration for each Cs.

**Notes**

You might get slightly different results with the solver liblinear than with the others since this uses LIBLINEAR which penalizes the intercept.

Changed in version 0.19: The “copy” parameter was removed.

**sklearn.utils.safe_indexing**

**Warning:** DEPRECATED

**sklearn.utils.safe_indexing**(*X, indices, axis=0*)  
DEPRECATED: safe_indexing is deprecated in version 0.22 and will be removed in version 0.24.

Return rows, items or columns of X using indices.

Deprecation since version 0.22: This function was deprecated in version 0.22 and will be removed in version 0.24.

**Parameters**

- **X**  [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series]  
  Data from which to sample rows, items or columns. list are only supported when axis=0.

- **indices**  bool, int, str, slice, array-like  
  • If axis=0, boolean and integer array-like, integer slice, and scalar integer are supported.
  • If axis=1:
    - to select a single column, indices can be of int type for all X types and str only for dataframe. The selected subset will be 1D, unless X is a sparse matrix in which case it will be 2D.
    - to select multiples columns, indices can be one of the following: list, array, slice. The type used in these containers can be one of the following: int, ‘bool’ and str. However, str is only supported when X is a dataframe. The selected subset will be 2D.

- **axis**  [int, default=0] The axis along which X will be subsampled. axis=0 will select rows while axis=1 will select columns.

**Returns**

- **subset**  Subset of X on axis 0 or 1.

**Notes**

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.
**ensemble.partial_dependence.partial_dependence**

DEPRECATED: The function ensemble.partial_dependence has been deprecated in favour of inspection.partial_dependence in 0.21 and will be removed in 0.23.

**sklearn.ensemble.partial_dependence.partial_dependence**

DEPRECATED: The function ensemble.partial_dependence has been deprecated in favour of sklearn.inspection.plot_partial_dependence in 0.21 and will be removed in 0.23.

Partial dependence of target_variables.

Partial dependence plots show the dependence between the joint values of the target_variables and the function represented by the gbrt.

Read more in the User Guide.

Deprecated since version 0.21: This function was deprecated in version 0.21 in favor of sklearn.inspection.partial_dependence and will be removed in 0.23.

**Parameters**

- **gbrr** [BaseGradientBoosting]
  A fitted gradient boosting model.

- **target_variables** [array-like, dtype=int] The target features for which the partial dependency should be computed (size should be smaller than 3 for visual renderings).

- **grid** [array-like of shape (n_points, n_target_variables)] The grid of target_variables values for which the partial dependency should be evaluated (either grid or X must be specified).

- **X** [array-like of shape (n_samples, n_features)] The data on which gbrt was trained. It is used to generate a grid for the target_variables. The grid comprises grid_resolution equally spaced points between the two percentiles.

- **percentiles** [(low, high), default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the grid. Only if X is not None.

- **grid_resolution** [int, default=100] The number of equally spaced points on the grid.

**Returns**

- **pdp** [array, shape=(n_classes, n_points)]

  The partial dependence function evaluated on the grid. For regression and binary classification n_classes==1.
axes [seq of ndarray or None] The axes with which the grid has been created or None if the grid has been given.

Examples

```python
>>> samples = [[0, 0, 2], [1, 0, 0]]
>>> labels = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(samples, labels)
>>> kwargs = dict(X=samples, percentiles=(0, 1), grid_resolution=2)
>>> partial_dependence(gb, [0], **kwargs) # doctest: +SKIP
(array([[-4.52..., 4.52...]]), [array([ 0., 1.])])
```

`sklearn.ensemble.partial_dependence.plot_partial_dependence`

`sklearn.ensemble.partial_dependence.plot_partial_dependence` *(gb, X, features, feature_names=None, label=None, n_cols=3, grid_resolution=100, percentiles=(0.05, 0.95), n_jobs=None, verbose=0, ax=None, line_kw=None, contour_kw=None, **fig_kw)*

DEPRECATED: The function ensemble.plot_partial_dependence has been deprecated in favor of sklearn.inspection.plot_partial_dependence in 0.21 and will be removed in 0.23.

Partial dependence plots for `features`.

The `len(features)` plots are arranged in a grid with `n_cols` columns. Two-way partial dependence plots are plotted as contour plots.

Read more in the User Guide.

Deprecated since version 0.21: This function was deprecated in version 0.21 in favor of `sklearn.inspection.plot_partial_dependence` and will be removed in 0.23.

Parameters

- `X` [array-like of shape (n_samples, n_features)] The data on which `gb` was trained.
- `features` [seq of ints, strings, or tuples of ints or strings] If `seq[i]` is an int or a tuple with one int value, a one-way PDP is created; if `seq[i]` is a tuple of two ints, a two-way PDP is created. If `feature_names` is specified and `seq[i]` is an int, `seq[i]` must be < `len(feature_names)`. If `seq[i]` is a string, `feature_names` must be specified, and `seq[i]` must be in `feature_names`.
- `feature_names` [seq of str] Name of each feature; `feature_names[i]` holds the name of the feature with index i.
label [object] The class label for which the PDPs should be computed. Only if gbrt is a multi-class model. Must be in gbrt.classes_.

n_cols [int] The number of columns in the grid plot (default: 3).

grid_resolution [int, default=100] The number of equally spaced points on the axes.

percentiles [(low, high), default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the PDP axes.

n_jobs [int or None, optional (default=None)] None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int] Verbose output during PD computations. Defaults to 0.

ax [Matplotlib axis object, default None] An axis object onto which the plots will be drawn.

line_kw [dict] Dict with keywords passed to the matplotlib.pyplot.plot call. For one-way partial dependence plots.

contour_kw [dict] Dict with keywords passed to the matplotlib.pyplot.plot call. For two-way partial dependence plots.

**fig_kw [dict] Dict with keywords passed to the figure() call. Note that all keywords not recognized above will be automatically included here.

Returns

fig [figure]

The Matplotlib Figure object.

axs [seq of Axis objects] A seq of Axis objects, one for each subplot.

Examples

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> X, y = make_friedman1()
>>> clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
>>> fig, axs = plot_partial_dependence(clf, X, [0, (0, 1)]) #doctest: +SKIP
...```
8.1 Contributing

This project is a community effort, and everyone is welcome to contribute.

The project is hosted on https://github.com/scikit-learn/scikit-learn

The decision making process and governance structure of scikit-learn is laid out in the governance document: Scikit-learn governance and decision-making.

Scikit-learn is somewhat selective when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See Issues for New Contributors to get started.

<table>
<thead>
<tr>
<th>Our community, our values</th>
</tr>
</thead>
<tbody>
<tr>
<td>We are a community based on openness and friendly, didactic, discussions.</td>
</tr>
<tr>
<td>We aspire to treat everybody equally, and value their contributions.</td>
</tr>
<tr>
<td>Decisions are made based on technical merit and consensus.</td>
</tr>
<tr>
<td>Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.</td>
</tr>
<tr>
<td>We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: <a href="https://www.python.org/psf/codeofconduct/">https://www.python.org/psf/codeofconduct/</a></td>
</tr>
</tbody>
</table>

In case you experience issues using this package, do not hesitate to submit a ticket to the GitHub issue tracker. You are also welcome to post feature requests or pull requests.

8.1.1 Ways to contribute

There are many ways to contribute to scikit-learn, with the most common ones being contribution of code or documentation to the project. Improving the documentation is no less important than improving the library itself. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request. Full documentation can be found under the doc/ directory.

But there are many other ways to help. In particular answering queries on the issue tracker, investigating bugs, and reviewing other developers’ pull requests are very valuable contributions that decrease the burden on the project maintainers.
Another way to contribute is to report issues you’re facing, and give a “thumbs up” on issues that others reported and that are relevant to you. It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply star to say “I use it”:

In case a contribution/issue involves changes to the API principles or changes to dependencies or supported versions, it must be backed by a Enhancement proposals (SLEPs), where a SLEP must be submitted as a pull-request to enhancement proposals using the SLEP template and follows the decision-making process outlined in Scikit-learn governance and decision-making.

 Contributing to related projects

Scikit-learn thrives in an ecosystem of several related projects, which also may have relevant issues to work on, including smaller projects such as:

- scikit-learn-contrib
- joblib
- sphinx-gallery
- numpydoc
- liac-arff

and larger projects:

- numpy
- scipy
- matplotlib
- and so on.

Look for issues marked “help wanted” or similar. Helping these projects may help Scikit-learn too. See also Related Projects.

8.1.2 Submitting a bug report or a feature request

We use GitHub issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

In case you experience issues using this package, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other issues or pull requests.
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our new algorithm requirements.
- If you are submitting a bug report, we strongly encourage you to follow the guidelines in How to make a good bug report.

How to make a good bug report

When you submit an issue to Github, please do your best to follow these guidelines! This will make it a lot easier to provide you with good feedback:
• The ideal bug report contains a **short reproducible code snippet**, this way anyone can try to reproduce the bug easily (see this for more details). If your snippet is longer than around 50 lines, please link to a gist or a github repo.

• If not feasible to include a reproducible snippet, please be specific about what **estimators and/or functions are involved and the shape of the data**.

• If an exception is raised, please **provide the full traceback**.

• Please include your **operating system type and version number**, as well as your **Python, scikit-learn, numpy, and scipy versions**. This information can be found by running the following code snippet:

```python
>>> import sklearn
>>> sklearn.show_versions()
```

**Note:** This utility function is only available in scikit-learn v0.20+. For previous versions, one has to explicitly run:

```python
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

• Please ensure all **code snippets and error messages are formatted in appropriate code blocks**. See Creating and highlighting code blocks for more details.

### 8.1.3 Contributing code

**Note:** To avoid duplicating work, it is highly advised that you search through the issue tracker and the PR list. If in doubt about duplicated work, or if you want to work on a non-trivial feature, it’s recommended to first open an issue in the issue tracker to get some feedbacks from core developers.

#### How to contribute

The preferred way to contribute to scikit-learn is to fork the main repository on GitHub, then submit a “pull request” (PR).

In the first few steps, we explain how to locally install scikit-learn, and how to set up your git repository:

1. **Create an account** on GitHub if you do not already have one.

2. Fork the **project repository**: click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub user account. For more details on how to fork a repository see this guide.

3. **Clone your fork of the scikit-learn repo** from your GitHub account to your local disk:

   ```bash
   $ git clone git@github.com:YourLogin/scikit-learn.git
   $ cd scikit-learn
   ```

4. Install the development dependencies:
$ pip install cython pytest pytest-cov flake8

5. Install scikit-learn in editable mode:

$ pip install --editable .

for more details about advanced installation, see the Building from source section.

6. Add the upstream remote. This saves a reference to the main scikit-learn repository, which you can use to keep your repository synchronized with the latest changes:

$ git remote add upstream https://github.com/scikit-learn/scikit-learn.git

You should now have a working installation of scikit-learn, and your git repository properly configured. The next steps now describe the process of modifying code and submitting a PR:

7. Synchronize your master branch with the upstream master branch:

$ git checkout master
$ git pull upstream master

8. Create a feature branch to hold your development changes:

$ git checkout -b my_feature

and start making changes. Always use a feature branch. It’s good practice to never work on the master branch!

9. Develop the feature on your feature branch on your computer, using Git to do the version control. When you’re done editing, add changed files using git add and then git commit:

$ git add modified_files
$ git commit

to record your changes in Git, then push the changes to your GitHub account with:

$ git push -u origin my_feature

10. Follow these instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

Note: If you are modifying a Cython module, you have to re-run step 5 after modifications and before testing them.

It is often helpful to keep your local feature branch synchronized with the latest changes of the main scikit-learn repository:

$ git fetch upstream
$ git merge upstream/master

Subsequently, you might need to solve the conflicts. You can refer to the Git documentation related to resolving merge conflict using the command line.

Learning git:

The Git documentation and http://try.github.io are excellent resources to get started with git, and understanding all of the commands shown here.
Pull request checklist

Before a PR can be merged, it needs to be approved by two core developers. Please prefix the title of your pull request with [MRG] if the contribution is complete and should be subjected to a detailed review. An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed [WIP] (to indicate a work in progress) and changed to [MRG] when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a task list in the PR description.

In order to ease the reviewing process, we recommend that your contribution complies with the following rules before marking a PR as [MRG]. The bolded ones are especially important:

1. **Give your pull request a helpful title** that summarises what your contribution does. This title will often become the commit message once merged so it should summarise your contribution for posterity. In some cases “Fix <ISSUE TITLE>” is enough. “Fix #<ISSUE NUMBER>” is never a good title.

2. **Make sure your code passes the tests.** The whole test suite can be run with pytest, but it is usually not recommended since it takes a long time. It is often enough to only run the test related to your changes: for example, if you changed something in sklearn/linear_model/logistic.py, running the following commands will usually be enough:
   - `pytest sklearn/linear_model/logistic.py` to make sure the doctest examples are correct
   - `pytest sklearn/linear_model/tests/test_logistic.py` to run the tests specific to the file
   - `pytest sklearn/linear_model` to test the whole `linear_model` module
   - `pytest doc/modules/linear_model.rst` to make sure the user guide examples are correct.
   - `pytest sklearn/tests/test_common.py -k LogisticRegression` to run all our estimator checks (specifically for LogisticRegression, if that’s the estimator you changed).

   There may be other failing tests, but they will be caught by the CI so you don’t need to run the whole test suite locally. For guidelines on how to use pytest efficiently, see the Useful pytest aliases and flags.

3. **Make sure your code is properly commented and documented**, and make sure the documentation renders properly. To build the documentation, please refer to our Documentation guidelines. The CI will also build the docs: please refer to Generated documentation on CircleCI.

4. **Tests are necessary for enhancements to be accepted.** Bug-fixes or new features should be provided with non-regression tests. These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. In the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.

5. **Make sure that your PR does not add PEP8 violations.** On a Unix-like system, you can run `make flake8-diff. flake8 path_to_file`, would work for any system, but please avoid reformatting parts of the file that your pull request doesn’t change, as it distracts from code review.

6. Follow the Coding guidelines.

7. When applicable, use the validation tools and scripts in the sklearn.utils submodule. A list of utility routines available for developers can be found in the Utilities for Developers page.

8. Often pull requests resolve one or more other issues (or pull requests). If merging your pull request means that some other issues/PRs should be closed, you should use keywords to create link to them (e.g., Fixes #1234; multiple issues/PRs are allowed as long as each one is preceded by a keyword). Upon merging, those issues/PRs will automatically be closed by GitHub. If your pull request is simply related to some other issues/PRs, create a link to them without using the keywords (e.g., See also #1234).

9. PRs should often substantiate the change, through benchmarks of performance and efficiency or through examples of usage. Examples also illustrate the features and intricacies of the library to users. Have a look at other
examples in the examples/ directory for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.

10. New features often need to be illustrated with narrative documentation in the user guide, with small code snippets. If relevant, please also add references in the literature, with PDF links when possible.

11. The user guide should also include expected time and space complexity of the algorithm and scalability, e.g. “this algorithm can scale to a large number of samples > 100000, but does not scale in dimensionality: n_features is expected to be lower than 100”.

You can also check our Code Review Guidelines to get an idea of what reviewers will expect.

You can check for common programming errors with the following tools:

- Code with a good unittest coverage (at least 80%, better 100%), check with:

  ```bash
  $ pip install pytest pytest-cov
  $ pytest --cov sklearn path/to/tests_for_package
  ```

  see also Testing and improving test coverage

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (please report on the mailing list or on the GitHub issue).

Also check out the How to optimize for speed guide for more details on profiling and Cython optimizations.

---

**Note:** The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

---

**Note:** For two very well documented and more detailed guides on development workflow, please pay a visit to the Scipy Development Workflow - and the Astropy Workflow for Developers sections.

---

**Continuous Integration (CI)**

- Azure pipelines are used for testing scikit-learn on Linux, Mac and Windows, with different dependencies and settings.
- CircleCI is used to build the docs for viewing, for linting with flake8, and for testing with PyPy on Linux

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

<table>
<thead>
<tr>
<th>Commit Marker</th>
<th>Message</th>
<th>Action Taken by CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>[scipy-dev]</td>
<td>Add a Travis build with our dependencies (numpy, scipy, etc ...) development builds</td>

Stalled pull requests

As contributing a feature can be a lengthy process, some pull requests appear inactive but unfinished. In such a case, taking them over is a great service for the project.

A good etiquette to take over is:

• **Determine if a PR is stalled**
  - A pull request may have the label “stalled” or “help wanted” if we have already identified it as a candidate for other contributors.
  - To decide whether an inactive PR is stalled, ask the contributor if she/he plans to continue working on the PR in the near future. Failure to respond within 2 weeks with an activity that moves the PR forward suggests that the PR is stalled and will result in tagging that PR with “help wanted”.
    
    Note that if a PR has received earlier comments on the contribution that have had no reply in a month, it is safe to assume that the PR is stalled and to shorten the wait time to one day.

    After a sprint, follow-up for un-merged PRs opened during sprint will be communicated to participants at the sprint, and those PRs will be tagged “sprint”. PRs tagged with “sprint” can be reassigned or declared stalled by sprint leaders.

• **Taking over a stalled PR**: To take over a PR, it is important to comment on the stalled PR that you are taking over and to link from the new PR to the old one. The new PR should be created by pulling from the old one.

Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle “easy” issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

---

**good first issue tag**

A great way to start contributing to scikit-learn is to pick an item from the list of good first issues in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. If you have already contributed to scikit-learn, you should look at Easy issues instead.

---

**Easy tag**

If you have already contributed to scikit-learn, another great way to contribute to scikit-learn is to pick an item from the list of Easy issues in the issue tracker. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

---

**help wanted tag**

We often use the help wanted tag to mark issues regardless of difficulty. Additionally, we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the help wanted tag can be found here.

Note that not all issues which need contributors will have this tag.
8.1.4 Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one),
tutorials, etc. reStructuredText documents live in the source code repository under the doc/ directory.

You can edit the documentation using any text editor, and then generate the HTML output by typing make from
the doc/ directory. Alternatively, make html may be used to generate the documentation with the example gallery
(which takes quite some time). The resulting HTML files will be placed in _build/html/stable and are viewable
in a web browser.

Building the documentation

First, make sure you have properly installed the development version.

Building the documentation requires installing some additional packages:

```
pip install sphinx sphinx-gallery numpydoc matplotlib Pillow pandas scikit-image packaging
```

To build the documentation, you need to be in the doc folder:

```
cd doc
```

In the vast majority of cases, you only need to generate the full web site, without the example gallery:

```
make
```

The documentation will be generated in the _build/html/stable directory. To also generate the example gallery
you can use:

```
make html
```

This will run all the examples, which takes a while. If you only want to generate a few examples, you can use:

```
EXAMPLES_PATTERN=your_regex_goes_here make html
```

This is particularly useful if you are modifying a few examples.

Set the environment variable NO_MATHJAX=1 if you intend to view the documentation in an offline setting.

To build the PDF manual, run:

```
make latexpdf
```

**Warning: Sphinx version**

While we do our best to have the documentation build under as many versions of Sphinx as possible, the different
versions tend to behave slightly differently. To get the best results, you should use the same version as the one we
used on CircleCI. Look at this github search to know the exact version.

**Guidelines for writing documentation**

It is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the
reader on what the algorithm does.
Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including "big O" \( \mathcal{O}(g(n)) \) complexities of the algorithm, as opposed to just rules of thumb, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works "under the hood".

Finally, follow the formatting rules below to make it consistently good:

- Add “See also” in docstrings for related classes/functions.
- “See also” in docstrings should be one line per reference, with a colon and an explanation, for example:

```python
See also
--------
SelectKBest : Select features based on the k highest scores.
SelectFpr : Select features based on a false positive rate test.
```

- When documenting the parameters and attributes, here is a list of some well-formatted examples:

```python
n_clusters : int, default=3
    The number of clusters detected by the algorithm.

some_param : {'hello', 'goodbye'}, bool or int, default=True
    The parameter description goes here, which can be either a string
    literal (either 'hello' or 'goodbye'), a bool, or an int. The default
    value is True.

array_parameter : (array-like, sparse matrix, dataframe) of shape (n_samples, n_
    features) or (n_samples,)
    This parameter accepts data in either of the mentioned forms, with one
    of the mentioned shapes. The default value is
    'np.ones(shape=(n_samples,))'.

list_param : list of int

typed_ndarray : ndarray of shape (n_samples,), dtype=np.int32

sample_weight : array-like of shape (n_samples,), default=None
```

In general have the following in mind:

1. Use Python basic types. (bool instead of boolean)
2. Use parenthesis for defining shapes: array-like of shape (n_samples,) or array-like of
   shape (n_samples, n_features)
3. For strings with multiple options, use brackets: input: {'log', 'squared', 'multinomial'}
4. 1D or 2D data can be a subset of (array-like, ndarray, sparse matrix, dataframe). Note
   that array-like can also be a list, while ndarray is explicitly only a numpy.ndarray.
5. When specifying the data type of a list, use of as a delimiter: list of int.
6. When specifying the dtype of an ndarray, use e.g. `dtype=np.int32` after defining the shape: `ndarray of shape (n_samples,)`, `dtype=np.int32`.

7. When the default is `None`, `None` only needs to be specified at the end with `default=None`. Be sure to include in the docstring, what it means for the parameter or attribute to be `None`.

- For unwritten formatting rules, try to follow existing good works:
  - For “References” in docstrings, see the Silhouette Coefficient (`sklearn.metrics.silhouette_score`).

- When editing reStructuredText (.rst) files, try to keep line length under 80 characters when possible (exceptions include links and tables).

- Before submitting you pull request check if your modifications have introduced new sphinx warnings and try to fix them.

**Generated documentation on CircleCI**

When you change the documentation in a pull request, CircleCI automatically builds it. To view the documentation generated by CircleCI:

- navigate to the bottom of your pull request page to see the CI statuses. You may need to click on “Show all checks” to see all the CI statuses.

- click on the CircleCI status with “doc” in the title.

- add `#artifacts` at the end of the URL. Note: you need to wait for the CircleCI build to finish before being able to look at the artifacts.

- once the artifacts are visible, navigate to `doc/_changed.html` to see a list of documentation pages that are likely to be affected by your pull request. Navigate to `doc/index.html` to see the full generated html documentation.

If you often need to look at the documentation generated by CircleCI, e.g. when reviewing pull requests, you may find this tip very handy.

### 8.1.5 Testing and improving test coverage

High-quality unit testing is a corner-stone of the scikit-learn development process. For this purpose, we use the `pytest` package. The tests are functions appropriately named, located in `tests` subdirectories, that check the validity of the algorithms and the different options of the code.

Running `pytest` in a folder will run all the tests of the corresponding subpackages. For a more detailed `pytest` workflow, please refer to the `Pull request checklist`.

We expect code coverage of new features to be at least around 90%.

**Writing matplotlib related tests**

Test fixtures ensure that a set of tests will be executing with the appropriate initialization and cleanup. The scikit-learn test suite implements a fixture which can be used with `matplotlib`.

The `pyplot` fixture should be used when a test function is dealing with `matplotlib`. `matplotlib` is a soft dependency and is not required. This fixture is in charge of skipping the tests if `matplotlib` is not installed. In addition, figures created during the tests will be automatically closed once the test function has been executed.

To use this fixture in a test function, one needs to pass it as an argument:
**Workflow to improve test coverage**

To test code coverage, you need to install the `coverage` package in addition to pytest.

1. Run `make test-coverage`. The output lists for each file the line numbers that are not tested.
2. Find a low hanging fruit, looking at which lines are not tested, write or adapt a test specifically for these lines.
3. Loop.

**8.1.6 Issue Tracker Tags**

All issues and pull requests on the GitHub issue tracker should have (at least) one of the following tags:

- **Bug / Crash**  Something is happening that clearly shouldn’t happen. Wrong results as well as unexpected errors from estimators go here.
- **Cleanup / Enhancement**  Improving performance, usability, consistency.
- **Documentation**  Missing, incorrect or sub-standard documentations and examples.
- **New Feature**  Feature requests and pull requests implementing a new feature.

There are four other tags to help new contributors:

- **good first issue**  This issue is ideal for a first contribution to scikit-learn. Ask for help if the formulation is unclear. If you have already contributed to scikit-learn, look at Easy issues instead.
- **Easy**  This issue can be tackled without much prior experience.
- **Moderate**  Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.
- **help wanted**  This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

**8.1.7 Maintaining backwards compatibility**

**Deprecation**

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function `zero_one` is renamed to `zero_one_loss`, we add the decorator `deprecated` (from `sklearn.utils`) to `zero_one_loss` and call `zero_one_loss` from that function:

```python
from ..utils import deprecated

def zero_one_loss(y_true, y_pred, normalize=True):
    # actual implementation
    pass
```

(continues on next page)
If an attribute is to be deprecated, use the decorator `deprecated` on a property. Please note that the `property` decorator should be placed before the `deprecated` decorator for the docstrings to be rendered properly. E.g., renaming an attribute `labels_` to `classes_` can be done as:

```python
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
           "will be removed in 0.15. Use 'classes_' instead")
@property
def labels_(self):
    return self.classes_
```

If a parameter has to be deprecated, a `FutureWarning` warning must be raised too. In the following example, `k` is deprecated and renamed to `n_clusters`:

```python
import warnings
def example_function(n_clusters=8, k='deprecated'):
    if k != 'deprecated':
        warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                      "will be removed in 0.15.",
                      FutureWarning)
    n_clusters = k
```

When the change is in a class, we validate and raise warning in `fit`:

```python
import warnings
class ExampleEstimator(BaseEstimator):
    def __init__(self, n_clusters=8, k='deprecated'):
        self.n_clusters = n_clusters
        self.k = k

    def fit(self, X, y):
        if self.k != 'deprecated':
            warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                          "will be removed in 0.15.",
                          FutureWarning)
            self._n_clusters = self.k
        else:
            self._n_clusters = self.n_clusters
```

As in these examples, the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed. If the deprecation happened in version 0.x-dev, the message should say deprecation occurred in version 0.x and the removal will be in 0.(x+2), so that users will have enough time to adapt their code to the new behaviour. For example, if the deprecation happened in version 0.18-dev, the message should say it happened in version 0.18 and the old behavior will be removed in version 0.20.

In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation warning as explained above. Use the `.. deprecated::` directive:
What’s more, a deprecation requires a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

**Change the default value of a parameter**

If the default value of a parameter needs to be changed, please replace the default value with a specific value (e.g., `warn`) and raise `FutureWarning` when users are using the default value. In the following example, we change the default value of `n_clusters` from 5 to 10 (current version is 0.20):

```python
import warnings

def example_function(n_clusters='warn'):
    if n_clusters == 'warn':
        warnings.warn("The default value of n_clusters will change from "
                      "5 to 10 in 0.22.", FutureWarning)
    n_clusters = 5
```

When the change is in a class, we validate and raise warning in `fit`:

```python
import warnings

class ExampleEstimator:
    def __init__(self, n_clusters='warn'):
        self.n_clusters = n_clusters

    def fit(self, X, y):
        if self.n_clusters == 'warn':
            warnings.warn("The default value of n_clusters will change from "
                          "5 to 10 in 0.22.", FutureWarning)
        self._n_clusters = 5
```

Similar to deprecations, the warning message should always give both the version in which the change happened and the version in which the old behavior will be removed. The docstring needs to be updated accordingly. We need a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

**8.1.8 Code Review Guidelines**

Reviewing code contributed to the project as PRs is a crucial component of scikit-learn development. We encourage anyone to start reviewing code of other developers. The code review process is often highly educational for everybody involved. This is particularly appropriate if it is a feature you would like to use, and so can respond critically about whether the PR meets your needs. While each pull request needs to be signed off by two core developers, you can speed up this process by providing your feedback.

Here are a few important aspects that need to be covered in any code review, from high-level questions to a more detailed check-list.

- Do we want this in the library? Is it likely to be used? Do you, as a scikit-learn user, like the change and intend to use it? Is it in the scope of scikit-learn? Will the cost of maintaining a new feature be worth its benefits?
• Is the code consistent with the API of scikit-learn? Are public functions/classes/parameters well named and intuitively designed?

• Are all public functions/classes and their parameters, return types, and stored attributes named according to scikit-learn conventions and documented clearly?

• Is any new functionality described in the user-guide and illustrated with examples?

• Is every public function/class tested? Are a reasonable set of parameters, their values, value types, and combinations tested? Do the tests validate that the code is correct, i.e. doing what the documentation says it does? If the change is a bug-fix, is a non-regression test included? Look at this to get started with testing in Python.

• Do the tests pass in the continuous integration build? If appropriate, help the contributor understand why tests failed.

• Do the tests cover every line of code (see the coverage report in the build log)? If not, are the lines missing coverage good exceptions?

• Is the code easy to read and low on redundancy? Should variable names be improved for clarity or consistency? Should comments be added? Should comments be removed as unhelpful or extraneous?

• Could the code easily be rewritten to run much more efficiently for relevant settings?

• Is the code backwards compatible with previous versions? (or is a deprecation cycle necessary?)

• Will the new code add any dependencies on other libraries? (this is unlikely to be accepted)

• Does the documentation render properly (see the Documentation section for more details), and are the plots instructive?

Standard replies for reviewing includes some frequent comments that reviewers may make.

8.1.9 Reading the existing code base

Reading and digesting an existing code base is always a difficult exercise that takes time and experience to master. Even though we try to write simple code in general, understanding the code can seem overwhelming at first, given the sheer size of the project. Here is a list of tips that may help make this task easier and faster (in no particular order).

• Get acquainted with the APIs of scikit-learn objects: understand what fit, predict, transform, etc. are used for.

• Before diving into reading the code of a function / class, go through the docstrings first and try to get an idea of what each parameter / attribute is doing. It may also help to stop a minute and think how would I do this myself if I had to?

• The trickiest thing is often to identify which portions of the code are relevant, and which are not. In scikit-learn a lot of input checking is performed, especially at the beginning of the fit methods. Sometimes, only a very small portion of the code is doing the actual job. For example looking at the fit() method of sklearn.linear_model.LinearRegression, what you’re looking for might just be the call the scipy.linalg.lstsq, but it is buried into multiple lines of input checking and the handling of different kinds of parameters.

• Due to the use of Inheritance, some methods may be implemented in parent classes. All estimators inherit at least from BaseEstimator, and from a Mixin class (e.g. ClassifierMixin) that enables default behaviour depending on the nature of the estimator (classifier, regressor, transformer, etc.).

• Sometimes, reading the tests for a given function will give you an idea of what its intended purpose is. You can use git grep (see below) to find all the tests written for a function. Most tests for a specific function/class are placed under the tests/ folder of the module

• You’ll often see code looking like this: out = Parallel(...) (delayed(some_function)(param) for param in some_iterable). This runs
some_function in parallel using Joblib. out is then an iterable containing the values returned by some_function for each call.

- We use Cython to write fast code. Cython code is located in .pyx and .pxd files. Cython code has a more C-like flavor: we use pointers, perform manual memory allocation, etc. Having some minimal experience in C / C++ is pretty much mandatory here.
- Master your tools.
  - With such a big project, being efficient with your favorite editor or IDE goes a long way towards digesting the code base. Being able to quickly jump (or peek) to a function/class/attribute definition helps a lot. So does being able to quickly see where a given name is used in a file.
  - git also has some built-in killer features. It is often useful to understand how a file changed over time, using e.g. git blame (manual). This can also be done directly on GitHub. git grep (examples) is also extremely useful to see every occurrence of a pattern (e.g. a function call or a variable) in the code base.

8.2 Developing scikit-learn estimators

Whether you are proposing an estimator for inclusion in scikit-learn, developing a separate package compatible with scikit-learn, or implementing custom components for your own projects, this chapter details how to develop objects that safely interact with scikit-learn Pipelines and model selection tools.

8.2.1 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.

Elements of the scikit-learn API are described more definitively in the Glossary of Common Terms and API Elements.

Different objects

The main objects in scikit-learn are (one class can implement multiple interfaces):

**Estimator** The base object, implements a fit method to learn from data, either:

```python
estimator = estimator.fit(data, targets)
```

or:

```python
estimator = estimator.fit(data)
```

**Predictor** For supervised learning, or some unsupervised problems, implements:

```python
prediction = predictor.predict(data)
```

Classification algorithms usually also offer a way to quantify certainty of a prediction, either using decision_function or predict_proba:

```python
probability = predictor.predict_proba(data)
```

**Transformer** For filtering or modifying the data, in a supervised or unsupervised way, implements:
When fitting and transforming can be performed much more efficiently together than separately, implements:

\[
\text{new_data} = \text{transformer.fit_transform(data)}
\]

**Model** A model that can give a goodness of fit measure or a likelihood of unseen data, implements (higher is better):

\[
\text{score} = \text{model.score(data)}
\]

### Estimators

The API has one predominant object: the estimator. A estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the fit method:

\[
\text{estimator.fit(X, y)}
\]

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`.

### Instantiation

This concerns the creation of an object. The object’s `__init__` method might accept constants as arguments that determine the estimator’s behavior (like the C constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:

\[
\text{clf2 = SVC(C=2.3)}
\]

\[
\text{clf3 = SVC([[1, 2], [2, 3]], [-1, 1]) \# WRONG!}
\]

The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the “Attributes” section, but rather under the “Parameters” section for that estimator.

In addition, **every keyword argument accepted by `__init__` should correspond to an attribute on the instance**. Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```python
def __init__(self, param1=1, param2=2):
    self.param1 = param1
    self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:
The reason for postponing the validation is that the same validation would have to be performed in set_params, which is used in algorithms like GridSearchCV.

### Fitting

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the fit() method.

The fit() method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using X and y, but the object holds no reference to X and y. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the predict method.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>array-like, shape (n_samples, n_features)</td>
</tr>
<tr>
<td>y</td>
<td>array, shape (n_samples,)</td>
</tr>
<tr>
<td>kwargs</td>
<td>optional data-dependent parameters.</td>
</tr>
</tbody>
</table>

X.shape[0] should be the same as y.shape[0]. If this requisite is not met, an exception of type ValueError should be raised.

y might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a y=None keyword argument in the second position that is just ignored by the estimator. For the same reason, fit_predict, fit_transform, score and partial_fit methods need to accept a y argument in the second place if they are implemented.

The method should return the object (self). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```python
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, fit can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an __init__ keyword argument. fit parameters should be restricted to directly data dependent variables. For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix X are data dependent. A tolerance stopping criterion tol is not directly data dependent (although the optimal value according to some scoring function probably is).

When fit is called, any previous call to fit should be ignored. In general, calling estimator.fit(X1) and then estimator.fit(X2) should be the same as only calling estimator.fit(X2). However, this may not be true in practice when fit depends on some random process, see random_state. Another exception to this rule is when the hyper-parameter warm_start is set to True for estimators that support it. warm_start=True means that the previous state of the trainable parameters of the estimator are reused instead of using the default initialization strategy.
Estimated Attributes

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a `coef_` attribute after `fit` has been called.

The estimated attributes are expected to be overridden when you call `fit` a second time.

Optional Arguments

In iterative algorithms, the number of iterations should be specified by an integer called `n_iter`.

Pairwise Attributes

An estimator that accept `X` of shape `(n_samples, n_samples)` and defines a `pairwise` property equal to True allows for cross-validation of the dataset, e.g. when `X` is a precomputed kernel matrix. Specifically, the `pairwise` property is used by `utils.metaestimators._safe_split` to slice rows and columns.

8.2.2 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running `utils.estimator_checks.check_estimator` on the class:

```python
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC
>>> check_estimator(LinearSVC)  # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as `model_selection.GridSearchCV` and `pipeline.Pipeline`.

Setting `generate_only=True` returns a generator that yields (estimator, check) tuples where the check can be called independently from each other, i.e. `check(estimator)`. This allows all checks to be run independently and report the checks that are failing. scikit-learn provides a pytest specific decorator, `parametrize_with_checks`, making it easier to test multiple estimators:

```python
from sklearn.utils.estimator_checks import parametrize_with_checks
from sklearn.linear_model import LogisticRegression
from sklearn.tree import DecisionTreeRegressor

@parametrize_with_checks([LogisticRegression, DecisionTreeRegressor])
def test_sklearn_compatible_estimator(estimator, check):
    check(estimator)
```

This decorator sets the `id` keyword in `pytest.mark.parametrize` exposing the name of the underlying estimator and check in the test name. This allows `pytest -k` to be used to specify which tests to run.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.
Project template:

We provide a project template which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of check_estimator
- directory structures and scripts to compile documentation and example galleries
- scripts to manage continuous integration (testing on Linux and Windows)
- instructions from getting started to publishing on PyPi

BaseEstimator and mixins:

We tend to use “duck typing”, so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from BaseEstimator and optionally the mixin classes in sklearn.base. For example, below is a custom classifier, with more examples included in the scikit-learn-contrib project template.

```python
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances

>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...     ...
...     def __init__(self, demo_param='demo'):
...         self.demo_param = demo_param
...     ...
...     def fit(self, X, y):
...         ...
...         # Check that X and y have correct shape
...         X, y = check_X_y(X, y)
...         # Store the classes seen during fit
...         self.classes_ = unique_labels(y)
...         ...
...         self.X_ = X
...         self.y_ = y
...         # Return the classifier
...         return self
...     ...
...     def predict(self, X):
...         ...
...         # Check is fit had been called
...         check_is_fitted(self)
...         # Input validation
...         X = check_array(X)
...         closest = np.argmin(euclidean_distances(X, self.X_), axis=1)
...         return self.y_[closest]
```
get_params and set_params

All scikit-learn estimators have get_params and set_params functions. The get_params function takes no arguments and returns a dict of the __init__ parameters of the estimator, together with their values. It must take one keyword argument, deep, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for deep should be true.

The set_params on the other hand takes as input a dict of the form 'parameter': value and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the get_params mechanism is not essential (see Cloning below), the set_params function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible __repr__ method, is to inherit from sklearn.base.BaseEstimator. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```python
def get_params(self, deep=True):
    # suppose this estimator has parameters "alpha" and "recursive"
    return {"alpha": self.alpha, "recursive": self.recursive}

def set_params(self, **parameters):
    for parameter, value in parameters.items():
        setattr(self, parameter, value)
    return self
```

Parameters and init

As model_selection.GridSearchCV uses set_params to apply parameter setting to estimators, it is essential that calling set_params has the same effect as setting parameters using the __init__ method. The easiest and recommended way to accomplish this is to not do any parameter validation in __init__. All logic behind estimator parameters, like translating string arguments into functions, should be done in fit.

Also it is expected that parameters with trailing _ are not to be set inside the __init__ method. All and only the public attributes set by fit have a trailing _. As a result the existence of parameters with trailing _ is used to check if the estimator has been fitted.

Cloning

For use with the model_selection module, an estimator must support the base.clone function to replicate an estimator. This can be done by providing a get_params method. If get_params is present, then clone(estimator) will be an instance of type(estimator) on which set_params has been called with clones of the result of estimator.get_params().

Objects that do not provide this method will be deep-copied (using the Python standard function copy.deepcopy) if safe=False is passed to clone.

Pipeline compatibility

For an estimator to be usable together with pipeline.Pipeline in any but the last step, it needs to provide a fit or fit_transform function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a transform function. There are no special requirements for the last step in a pipeline, except that it has a fit function. All fit and fit_transform functions must take arguments X, y, even if y is not used. Similarly, for score to be usable, the last step of the pipeline needs to have a score function that accepts an optional y.
Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in `model_selection.GridSearchCV` and `model_selection.cross_val_score` defaults to being stratified when used on a classifier, but not otherwise. Similarly, scorers for average precision that take a continuous prediction need to call `decision_function` for classifiers, but `predict` for regressors. This distinction between classifiers and regressors is implemented using the `_estimator_type` attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from `ClassifierMixin`, `RegressorMixin` or `ClusterMixin` will set the attribute automatically. When a meta-estimator needs to distinguish among estimator types, instead of checking `_estimator_type` directly, helpers like `base.is_classifier` should be used.

Specific models

Classifiers should accept `y` (target) arguments to `fit` that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of classes in a `classes_` attribute or property. The order of class labels in this attribute should match the order in which `predict_proba`, `predict_log_proba` and `decision_function` return their values. The easiest way to achieve this is to put:

```python
self.classes_, y = np.unique(y, return_inverse=True)
```

in `fit`. This returns a new `y` that contains class indexes, rather than labels, in the range [0, n_classes).

A classifier's `predict` method should return arrays containing class labels from `classes_`. In a classifier that implements `decision_function`, this can be achieved with:

```python
def predict(self, X):
    D = self.decision_function(X)
    return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called `coef_`, and the independent term is stored in `intercept_`. `sklearn.linear_model._base` contains a few base classes and mixins that implement common linear model patterns.

The `sklearn.utils.multiclass` module contains useful functions for working with multiclass and multilabel problems.

Estimator Tags

**Warning:** The estimator tags are experimental and the API is subject to change.

Scikit-learn introduced estimator tags in version 0.21. These are annotations of estimators that allow programmatic inspection of their capabilities, such as sparse matrix support, supported output types and supported methods. The estimator tags are a dictionary returned by the method `_get_tags()`. These tags are used by the common tests and the `sklearn.utils.estimator_checks.check_estimator` function to decide what tests to run and what input data is appropriate. Tags can depend on estimator parameters or even system architecture and can in general only be determined at runtime.

The default value of all tags except for `X_types` and `requires_fit` is `False`. These are defined in the `BaseEstimator` class.

The current set of estimator tags are:
**non_deterministic** whether the estimator is not deterministic given a fixed `random_state`

**requires_positive_X** whether the estimator requires positive X.

**requires_positive_y** whether the estimator requires a positive y (only applicable for regression).

**no_validation** whether the estimator skips input-validation. This is only meant for stateless and dummy transformers!

**multioutput - unused for now** whether a regressor supports multi-target outputs or a classifier supports multi-class multi-output.

**multilabel** whether the estimator supports multilabel output

**stateless** whether the estimator needs access to data for fitting. Even though an estimator is stateless, it might still need a call to `fit` for initialization.

**requires_fit** whether the estimator requires to be fitted before calling one of `transform`, `predict`, `predict_proba`, or `decision_function`.

**allow_nan** whether the estimator supports data with missing values encoded as `np.NaN`

**poor_score** whether the estimator fails to provide a “reasonable” test-set score, which currently for regression is an R2 of 0.5 on a subset of the boston housing dataset, and for classification an accuracy of 0.83 on `make_blobs(n_samples=300, random_state=0)`. These datasets and values are based on current estimators in sklearn and might be replaced by something more systematic.

**multioutput_only** whether estimator supports only multi-output classification or regression.

**binary_only** whether estimator supports binary classification but lacks multi-class classification support.

**_skip_test** whether to skip common tests entirely. Don’t use this unless you have a very good reason.

**X_types** Supported input types for X as list of strings. Tests are currently only run if ‘2darray’ is contained in the list, signifying that the estimator takes continuous 2d numpy arrays as input. The default value is ['2darray']. Other possible types are 'string', 'sparse', 'categorical', 'dict', '1dlabels' and '2dlabels'. The goal is that in the future the supported input type will determine the data used during testing, in particular for 'string', 'sparse' and 'categorical' data. For now, the test for sparse data do not make use of the 'sparse' tag.

To override the tags of a child class, one must define the `_more_tags()` method and return a dict with the desired tags, e.g:

```python
class MyMultiOutputEstimator(BaseEstimator):
    def _more_tags(self):
        return {'multioutput_only': True,
                'non_deterministic': True}
```

In addition to the tags, estimators also need to declare any non-optional parameters to `__init__` in the `_required_parameters` class attribute, which is a list or tuple. If `_required_parameters` is only ['"estimator"'] or ['"base_estimator"'], then the estimator will be instantiated with an instance of `LinearDiscriminantAnalysis` (or `RidgeRegression` if the estimator is a regressor) in the tests. The choice of these two models is somewhat idiosyncratic but both should provide robust closed-form solutions.

### 8.2.3 Coding guidelines

The following are some guidelines on how new code should be written for inclusion in scikit-learn, and which may be appropriate to adopt in external projects. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.
Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in PEP8 that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: n_samples rather than nsamples.
- Avoid multiple statements on one line. Prefer a line return after a control flow statement (if/for).
- Use relative imports for references inside scikit-learn.
- Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if sklearn.foo exports a class or function that is implemented in sklearn.foo.bar.baz, the test should import it from sklearn.foo.
- Please don’t use import * in any case. It is considered harmful by the official Python recommendations. It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like pyflakes to automatically find bugs in scikit-learn.
- Use the numpy docstring standard in all your docstrings.

A good example of code that we like can be found here.

Input validation

The module sklearn.utils contains various functions for doing input validation and conversion. Sometimes, np.asarray suffices for validation; do not use np.asanyarray or np.atleast_2d, since those let NumPy’s np.matrix through, which has a different API (e.g., * means dot product on np.matrix, but Hadamard product on np.ndarray).

In other cases, be sure to call check_array on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which scipy.sparse matrices must be accepted.

For more information, refer to the Utilities for Developers page.

Random Numbers

If your code depends on a random number generator, do not use numpy.random.random() or similar routines. To ensure repeatability in error checking, the routine should accept a keyword random_state and use this to construct a numpy.random.RandomState object. See sklearn.utils.check_random_state in Utilities for Developers.

Here’s a simple example of code using some of the above guidelines:

```python
from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
    """
    Choose a random point from X
    """
    Parameters
    ----------
    X : array-like, shape (n_samples, n_features)
        array representing the data
    random_state : RandomState or an int seed (0 by default)
        A random number generator instance to define the state of the random permutations generator.
```

(continues on next page)
Returns
------
x : numpy array, shape (n_features,)
   A random point selected from X
   
X = check_array(X)
random_state = check_random_state(random_state)
i = random_state.randint(X.shape[0])
return X[i]

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.

First off, the estimator should take a random_state argument to its __init__ with a default value of None. It should store that argument's value, unmodified, in an attribute random_state. fit can call check_random_state on that attribute to get an actual random number generator. If, for some reason, randomness is needed after fit, the RNG should be stored in an attribute random_state_. The following example should make this clear:

```python
class GaussianNoise(BaseEstimator, TransformerMixin):
    """This estimator ignores its input and returns random Gaussian noise.
    It also does not adhere to all scikit-learn conventions,
    but showcases how to handle randomness."
    
    def __init__(self, n_components=100, random_state=None):
        self.random_state = random_state

        # the arguments are ignored anyway, so we make them optional
        def fit(self, X=None, y=None):
            self.random_state_ = check_random_state(self.random_state)

        def transform(self, X):
            n_samples = X.shape[0]
            return self.random_state_.randn(n_samples, n_components)
```

The reason for this setup is reproducibility: when an estimator is fit twice to the same data, it should produce an identical model both times, hence the validation in fit, not __init__.

8.3 Developers’ Tips and Tricks

8.3.1 Productivity and sanity-preserving tips

In this section we gather some useful advice and tools that may increase your quality-of-life when reviewing pull requests, running unit tests, and so forth. Some of these tricks consist of userscripts that require a browser extension such as TamperMonkey or GreaseMonkey; to set up userscripts you must have one of these extensions installed, enabled and running. We provide userscripts as GitHub gists; to install them, click on the “Raw” button on the gist page.

Viewing the rendered HTML documentation for a pull request

We use CircleCI to build the HTML documentation for every pull request. To access that documentation, instructions are provided in the documentation section of the contributor guide. To save you a few clicks, we provide a userscript
that adds a button to every PR. After installing the userscript, navigate to any GitHub PR; a new button labeled “See CircleCI doc for this PR” should appear in the top-right area.

**Folding and unfolding outdated diffs on pull requests**

GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while. This userscript provides a shortcut (Control-Alt-P at the time of writing but look at the code to be sure) to unfold all such hidden discussions at once, so you can catch up.

**Checking out pull requests as remote-tracking branches**

In your local fork, add to your `.git/config`, under the `[remote "upstream"]` heading, the line:

```
fetch = +refs/pull/*/head:refs/remotes/upstream/pr/*
```

You may then use `git checkout pr/PR_NUMBER` to navigate to the code of the pull-request with the given number. (Read more in this gist.)

**Display code coverage in pull requests**

To overlay the code coverage reports generated by the CodeCov continuous integration, consider this browser extension. The coverage of each line will be displayed as a color background behind the line number.

**Useful pytest aliases and flags**

The full test suite takes fairly long to run. For faster iterations, it is possibly to select a subset of tests using pytest selectors. In particular, one can run a single test based on its node ID:

```
pytest -v sklearn/linear_model/tests/test_logistic.py::test_sparsify
```

or use the `-k pytest` parameter to select tests based on their name. For instance,:`

```
pytest sklearn/tests/test_common.py -v -k LogisticRegression
```

will run all *common tests* for the *LogisticRegression* estimator.

When a unit test fails, the following tricks can make debugging easier:

1. The command line argument `pytest -l` instructs pytest to print the local variables when a failure occurs.
2. The argument `pytest --pdb` drops into the Python debugger on failure. To instead drop into the rich IPython debugger `ipdb`, you may set up a shell alias to:

```
pytest --pdbcls=IPython.terminal.debugger:TerminalPdb --capture no
```

Other `pytest` options that may become useful include:

- `-x` which exits on the first failed test
- `--lf` to rerun the tests that failed on the previous run
- `--ff` to rerun all previous tests, running the ones that failed first
- `-s` so that pytest does not capture the output of `print()` statements
- `--tb=short` or `--tb=line` to control the length of the logs

8.3. Developers' Tips and Tricks
Since our continuous integration tests will error if `FutureWarning` isn’t properly caught, it is also recommended to run `pytest` along with the `-Werror::FutureWarning` flag.

## Standard replies for reviewing

It may be helpful to store some of these in GitHub’s saved replies for reviewing:

**Issue: Usage questions**

You’re asking a usage question. The issue tracker is mainly for bugs and new features. For usage questions, it is recommended to try [Stack Overflow](https://stackoverflow.com/questions/tagged/scikit-learn) or [the Mailing List](https://mail.python.org/mailman/listinfo/scikit-learn).

**Issue: You’re welcome to update the docs**

Please feel free to offer a pull request updating the documentation if you feel it could be improved.

**Issue: Self-contained example for bug**

Please provide [self-contained example code](https://stackoverflow.com/help/mcve), including imports and data (if possible), so that other contributors can just run it and reproduce your issue. Ideally your example code should be minimal.

**Issue: Software versions**

To help diagnose your issue, please paste the output of:

```
import sklearn; sklearn.show_versions()
```

Thanks.

**Issue: Code blocks**

Readability can be greatly improved if you [format](https://help.github.com/articles/creating-and-highlighting-code-blocks/) your code snippets and complete error messages appropriately. For example:

```
```
print(something)
```

 generates:
```
```
print(something)
```

And:

```
```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```

 generates:
```
```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
```
ImportError: No module named 'hello'
```
You can edit your issue descriptions and comments at any time to improve readability. This helps maintainers a lot. Thanks!
```

**Issue/Comment: Linking to code**

Friendly advice: for clarity's sake, you can link to code like [this](https://help.github.com/articles/creating-a-permanent-link-to-a-code-snippet/).

**Issue/Comment: Linking to comments**

Please use links to comments, which make it a lot easier to see what you are referring to, rather than just linking to the issue. See [this](https://stackoverflow.com/questions/25163598/how-do-i-reference-a-specific-issue-comment-on-github) for more details.

**PR-NEW: Better description and title**

Thanks for the pull request! Please make the title of the PR more descriptive. The title will become the commit message when this is merged. You should state what issue (or PR) it fixes/resolves in the description using the syntax described [here](http://scikit-learn.org/dev/developers/contributing.html#contributing-pull-requests).

**PR-NEW: Fix #**

Please use "Fix #issueNumber" in your PR description (and you can do it more than once). This way the associated issue gets closed automatically when the PR is merged. For more details, look at [this](https://github.com/blog/1506-closing-issues-via-pull-requests).

**PR-NEW or Issue: Maintenance cost**

Every feature we include has a [maintenance cost](http://scikit-learn.org/dev/faq.html#why-are-you-so-selective-on-what-algorithms-you-include-in-scikit-learn). Our maintainers are mostly volunteers. For a new feature to be included, we need evidence that it is often useful and, ideally, [well-established](http://scikit-learn.org/dev/faq.html#what-are-the-inclusion-criteria-for-new-algorithms) in the literature or in practice. That doesn't stop you implementing it for yourself and publishing it in a separate repository, or even [scikit-learn-contrib](https://scikit-learn-contrib.github.io).

**PR-WIP: What’s needed before merge?**

Please clarify (perhaps as a TODO list in the PR description) what work you believe still needs to be done before it can be reviewed for merge. When it is ready, please prefix the PR title with `[MRG]`.

**PR-WIP: Regression test needed**

Please add a [non-regression test](https://en.wikipedia.org/wiki/Non-regression_testing) that would fail at master but pass in this PR.

**PR-WIP: PEP8**
You have some [PEP8](https://www.python.org/dev/peps/pep-0008/) violations, whose details you can see in the Circle CI `lint` job. It might be worth configuring your code editor to check for such errors on the fly, so you can catch them before committing.

**PR-MRG: Patience**

Before merging, we generally require two core developers to agree that your pull request is desirable and ready. [Please be patient](http://scikit-learn.org/dev/faq.html#why-is-my-pull-request-not-getting-any-attention), as we mostly rely on volunteered time from busy core developers. (You are also welcome to help us out with [reviewing other PRs](http://scikit-learn.org/dev/developers/contributing.html#code-review-guidelines).)

**PR-MRG: Add to what’s new**

Please add an entry to the change log at `doc/whats_new/v*.rst`. Like the other entries there, please reference this pull request with `:pr:` and credit yourself (and other contributors if applicable) with `:user:`.

**PR: Don’t change unrelated**

Please do not change unrelated lines. It makes your contribution harder to review and may introduce merge conflicts to other pull requests.

### 8.3.2 Debugging memory errors in Cython with valgrind

While python/numpy’s built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn is written in cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is valgrind.

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install valgrind on your system.
2. Download the python valgrind suppression file: [valgrind-python.supp](http).
3. Follow the directions in the README.valgrind file to customize your python suppressions. If you don’t, you will have spurious output coming related to the python interpreter instead of your own code.
4. Run valgrind as follows:

   ```bash
test> valgrind -v --suppressions=valgrind-python.supp python my_test_script.py
   ```

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the valgrind web site.
8.4 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in *sklearn.utils*, and include tools in a number of categories. All the following functions and classes are in the module *sklearn.utils*.

**Warning:** These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.

### 8.4.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- **assert_all_finite:** Throw an error if array contains NaNs or Infs.
- **as_float_array:** convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- **check_array:** check that input is a 2D array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1D or N-dimensional arrays. Calls *assert_all_finite* by default.
- **check_X_y:** check that X and y have consistent length, calls check_array on X, and column_or_1d on y. For multilabel classification or multitarget regression, specify multi_output=True, in which case check_array will be called on y.
- **indexable:** check that all input arrays have consistent length and can be sliced or indexed using safe_index. This is used to validate input for cross-validation.
- **validation.check_memory** checks that input is *joblib.Memory*-like, which means that it can be converted into a *sklearn.utils.Memory* instance (typically a str denoting the cachedir) or has the same interface.

If your code relies on a random number generator, it should never use functions like *numpy.random.random* or *numpy.random.normal*. This approach can lead to repeatability issues in unit tests. Instead, a *numpy.random.RandomState* object should be used, which is built from a *random_state* argument passed to the class or function. The function *check_random_state*, below, can then be used to create a random number generator object.

- **check_random_state:** create a *numpy.random.RandomState* object from a parameter *random_state*.
  - If *random_state* is *None* or *np.random*, then a randomly-initialized *RandomState* object is returned.
  - If *random_state* is an integer, then it is used to seed a new *RandomState* object.
  - If *random_state* is a *RandomState* object, then it is passed through.

For example:

```python
>>> from sklearn.utils import check_random_state
>>> random_state = 0
>>> random_state = check_random_state(random_state)
>>> random_state.rand(4)
array([0.5488135 , 0.71518937, 0.60276338, 0.54488318])
```

When developing your own scikit-learn compatible estimator, the following helpers are available.
8.4.2 Efficient Linear Algebra & Array Operations

- `extmath.randomized_range_finder`: construct an orthonormal matrix whose range approximates the range of the input. This is used in `extmath.randomized_svd`, below.

- `extmath.randomized_svd`: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.

- `arrayfuncs.cholesky_delete`: (used in `sklearn.linear_model.lars_path`) Remove an item from a cholesky factorization.

- `arrayfuncs.min_pos`: (used in `sklearn.linear_model.least_angle`) Find the minimum of the positive values within an array.

- `extmath.fast_logdet`: efficiently compute the log of the determinant of a matrix.

- `extmath.density`: efficiently compute the density of a sparse vector.

- `extmath.safe_sparse_dot`: dot product which will correctly handle `scipy.sparse` inputs. If the inputs are dense, it is equivalent to `numpy.dot`.

- `extmath.weighted_mode`: an extension of `scipy.stats.mode` which allows each item to have a real-valued weight.

- `resample`: Resample arrays or sparse matrices in a consistent way. used in `shuffle`, below.

- `shuffle`: Shuffle arrays or sparse matrices in a consistent way. Used in `sklearn.cluster.k_means`.

8.4.3 Efficient Random Sampling

- `random.sample_without_replacement`: implements efficient algorithms for sampling n_samples integers from a population of size n_population without replacement.

8.4.4 Efficient Routines for Sparse Matrices

The `sklearn.utils.sparsefuncs` cython module hosts compiled extensions to efficiently process `scipy.sparse` data.

- `sparsefuncs.mean_variance_axis`: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in `sklearn.cluster.KMeans`.

- `sparsefuncs_fast.inplace_csr_row_normalize_l1` and `sparsefuncs_fast.inplace_csr_row_normalize_l2`: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in `sklearn.preprocessing.Normalizer`.

- `sparsefuncs.inplace_csr_column_scale`: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in `sklearn.preprocessing.StandardScaler`.
8.4.5 Graph Routines

- `graph.single_source_shortest_path_length`: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from networkx. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra’s algorithm from `graph_shortest_path`.

- `graph_shortest_path.graph_shortest_path`: (used in sklearn.manifold.Isomap) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra’s algorithm are available. The algorithm is most efficient when the connectivity matrix is a `scipy.sparse.csr_matrix`.

8.4.6 Testing Functions

- `all_estimators`: returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

8.4.7 Multiclass and multilabel utility function

- `multiclass.is_multilabel`: Helper function to check if the task is a multi-label classification one.

- `multiclass.unique_labels`: Helper function to extract an ordered array of unique labels from different formats of target.

8.4.8 Helper Functions

- `gen_even_slices`: generator to create n-packs of slices going up to n. Used in sklearn.decomposition.dict_learning and sklearn.cluster.k_means.

- `safe_mask`: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).

- `safe_sqr`: Helper function for unified squaring (**2) of array-likes, matrices and sparse matrices.

8.4.9 Hash Functions

- `murmurhash3_32` provides a python wrapper for the MurmurHash3_x86_32 C++ non cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```python
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True
>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```

The sklearn.utils.murmurhash module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.
8.4.10 Warnings and Exceptions

- **deprecated**: Decorator to mark a function or class as deprecated.
- **`sklearn.exceptions.ConvergenceWarning`**: Custom warning to catch convergence problems. Used in `sklearn.covariance.graphical_lasso`.

8.5 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

**Note:** While it is always useful to profile your code so as to check performance assumptions, it is also highly recommended to review the literature to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple algorithmic tricks, or by using another algorithm altogether that is better suited to the problem.

The section *A simple algorithmic trick: warm restarts* gives an example of such a trick.

8.5.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the readability of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to start implementing it in Python using Numpy and Scipy by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to replace any nested for loops by calls to equivalent Numpy array methods. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It’s generally a good idea to consider NumPy and SciPy performance tips: [https://scipy.github.io/old-wiki/pages/PerformanceTips](https://scipy.github.io/old-wiki/pages/PerformanceTips)

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. **Profile** the Python implementation to find the main bottleneck and isolate it in a dedicated module level function. This function will be reimplemented as a compiled extension module.

2. If there exists a well maintained BSD or MIT C/C++ implementation of the same algorithm that is not too big, you can write a Cython wrapper for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes `svm.LinearSVC`, `svm.SVC` and `linear_model.LogisticRegression` (wrappers for liblinear and libsvm).

3. Otherwise, write an optimized version of your Python function using Cython directly. This strategy is used for the `linear_model.ElasticNet` and `linear_model.SGDClassifier` classes for instance.

4. **Move the Python version of the function in the tests** and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.

5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have coarse grained parallelism that is amenable to multi-processing by using the `joblib.Parallel` class.

When using Cython, use either

```
$ python setup.py build_ext -i $ python setup.py install
```
to generate C files. You are responsible for adding .c/.cpp extensions along with build parameters in each submodule `setup.py`.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, Scipy and C/C++ compiler.

### 8.5.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of scikit-learn. Let us setup a new IPython session and load the digits dataset and as in the Recognizing hand-written digits example:

```python
In [1]: from sklearn.decomposition import NMF
In [2]: from sklearn.datasets import load_digits
In [3]: X, _ = load_digits(return_X_y=True)
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```python
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the `%prun` magic command:

```python
In [5]: %prun -l nmf.py NMF(n_components=16, tol=1e-2).fit(X)
14496 function calls in 1.682 CPU seconds
```

The `tottime` column is the most interesting: it gives to total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the `cumtime` column.

Note the use of the `-l nmf.py` that restricts the output to lines that contains the “nmf.py” string. This is useful to have a quick look at the hotspot of the nmf Python module it-self ignoring anything else.

Here is the beginning of the output of the same command without the `-l nmf.py` filter:

```python
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)
16159 function calls in 1.840 CPU seconds
```
Ordered by: internal time

<table>
<thead>
<tr>
<th>ncalls</th>
<th>tottime</th>
<th>percall</th>
<th>cumtime</th>
<th>percall</th>
<th>filename:lineno(function)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2833</td>
<td>0.653</td>
<td>0.000</td>
<td>0.653</td>
<td>0.000</td>
<td>{numpy.core._dotblas.dot}</td>
</tr>
<tr>
<td>46</td>
<td>0.651</td>
<td>0.014</td>
<td>1.636</td>
<td>0.036</td>
<td>nmf.py:151(_nls_subproblem)</td>
</tr>
<tr>
<td>1397</td>
<td>0.171</td>
<td>0.000</td>
<td>0.171</td>
<td>0.000</td>
<td>nmf.py:18(_Pos)</td>
</tr>
<tr>
<td>2780</td>
<td>0.167</td>
<td>0.000</td>
<td>0.167</td>
<td>0.000</td>
<td>(method 'sum' of 'numpy.ndarray')</td>
</tr>
<tr>
<td>1</td>
<td>0.064</td>
<td>0.064</td>
<td>1.840</td>
<td>1.840</td>
<td>nmf.py:352(fit_transform)</td>
</tr>
<tr>
<td>1542</td>
<td>0.043</td>
<td>0.000</td>
<td>0.043</td>
<td>0.000</td>
<td>(method 'flatten' of 'numpy.ndarray')</td>
</tr>
<tr>
<td>337</td>
<td>0.019</td>
<td>0.000</td>
<td>0.019</td>
<td>0.000</td>
<td>(method 'all' of 'numpy.ndarray')</td>
</tr>
<tr>
<td>2734</td>
<td>0.011</td>
<td>0.000</td>
<td>0.181</td>
<td>0.000</td>
<td>fromnumeric.py:1185(sum)</td>
</tr>
<tr>
<td>2</td>
<td>0.010</td>
<td>0.005</td>
<td>0.010</td>
<td>0.005</td>
<td>{numpy.linalg.lapack_lite.dgesdd}</td>
</tr>
<tr>
<td>748</td>
<td>0.009</td>
<td>0.000</td>
<td>0.065</td>
<td>0.000</td>
<td>nmf.py:28(norm)</td>
</tr>
</tbody>
</table>

The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably no huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by algorithmic improvements in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation).

It is however still interesting to check what’s happening inside the _nls_subproblem function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install line_profiler and wire it to IPython:

```
$ pip install line_profiler
```

- **Under IPython 0.13+**, first create a configuration profile:

```
$ ipython profile create
```

Then register the line_profiler extension in ~/.ipython/profile_default/ipython_config.py:

```
c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')
```

This will register the %lprun magic command in the IPython terminal application and the other frontends such as qtconsole and notebook.

Now restart IPython and let us use this new toy:

```
In [1]: from sklearn.datasets import load_digits

In [2]: from sklearn.decomposition import NMF
   ...: from sklearn.decomposition._nmf import _nls_subproblem

In [3]: X, _ = load_digits(return_X_y=True)

In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)
```

(continues on next page)
By looking at the top values of the % Time column it is really easy to pin-point the most expensive expressions that would deserve additional care.

### 8.5.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of memory_profiler. First, install the latest version:

```
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to line_profiler.

---

8.5. How to optimize for speed 2599
• Under IPython 0.11+, first create a configuration profile:

```
$ ipython profile create
```

Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:

```
c.TerminalIPythonApp.extensions.append('memory_profiler')
c.InteractiveShellApp.extensions.append('memory_profiler')
```

This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as qtconsole and notebook.

`%mprun` is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to `%lprun`, discussed in the previous section. For example, from the `memory_profiler` examples directory:

```
In [1]: from example import my_func
In [2]: %mprun -f my_func my_func()
Filename: example.py
Line #  Mem usage  Increment  Line Contents
-----------------------------------------------
3  @profile
4   5.97 MB   0.00 MB  def my_func():
5   13.61 MB   7.64 MB  a = [1] * (10 ** 6)
6   166.20 MB  152.59 MB  b = [2] * (2 * 10 ** 7)
7   13.61 MB  -152.59 MB  del b
8   13.61 MB   0.00 MB  return a
```

Another useful magic that `memory_profiler` defines is `%memit`, which is analogous to `%timeit`. It can be used as follows:

```
In [1]: import numpy as np
In [2]: %memit np.zeros(1e7)
```

maximum of 3: 76.402344 MB per loop

For more details, see the docstrings of the magics, using `%memit?` and `%mprun?`.

### 8.5.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation (e.g. for loops over vector components, nested evaluation of conditional expression, scalar arithmetic...), it is probably adequate to extract the hotspot portion of the code as a standalone function in a `.pyx` file, add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module.

The official documentation available at [http://docs.cython.org/](http://docs.cython.org/) contains a tutorial and reference guide for developing such a module. In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls...

- [https://www.youtube.com/watch?v=gMvkiQ-gOW8](https://www.youtube.com/watch?v=gMvkiQ-gOW8)
### Using OpenMP

Since scikit-learn can be built without OpenMP, it’s necessary to protect each direct call to OpenMP. This can be done using the following syntax:

```python
# importing OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
    cimport openmp

# calling OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
    max_threads = openmp.omp_get_max_threads()
ELSE:
    max_threads = 1
```

**Note:** Protecting the parallel loop, `prange`, is already done by cython.

### 8.5.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default Python profiler is useless: we need a dedicated tool to introspect what’s happening inside the compiled extension itself.

#### Using yep and gperftools

Easy profiling without special compilation options use yep:

- [https://pypi.org/project/yep/](https://pypi.org/project/yep/)
- [http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions](http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions)

#### Using gprof

In order to profile compiled Python extensions one could use `gprof` after having recompiled the project with `gcc -pg` and using the `python-dbg` variant of the interpreter on debian / ubuntu: however this approach requires to also have `numpy` and `scipy` recompiled with `-pg` which is rather complicated to get working.

Fortunately there exist two alternative profilers that don’t require you to recompile everything.

#### Using valgrind / callgrind / kcachegrind

**kcachegrind**

`yep` can be used to create a profiling report. `kcachegrind` provides a graphical environment to visualize this report:

```bash
# Run yep to profile some python script
python -m yep -c my_file.py

# open my_file.py.callgrind with kcachegrind
kcachegrind my_file.py.prof
```
8.5.6 Multi-core parallelism using joblib.Parallel

See joblib documentation

8.5.7 A simple algorithmic trick: warm restarts

See the glossary entry for warm_start

8.6 Installing the development version of scikit-learn

This section introduces how to install the master branch of scikit-learn. This can be done by either installing a nightly build or building from source.

8.6.1 Installing nightly builds

The continuous integration servers of the scikit-learn project build, test and upload wheel packages for the most recent Python version on a nightly basis.

Installing a nightly build is the quickest way to:

- try a new feature that will be shipped in the next release (that is, a feature from a pull-request that was recently merged to the master branch);
- check whether a bug you encountered has been fixed since the last release.

```
pip install --pre -f https://sklearn-nightly.scdn8.secure.raxcdn.com scikit-learn
```

8.6.2 Building from source

Building from source is required to work on a contribution (bug fix, new feature, code or documentation improvement).

1. Use Git to check out the latest source from the scikit-learn repository on Github:

```
git clone git://github.com/scikit-learn/scikit-learn.git
cd scikit-learn
```

If you plan on submitting a pull-request, you should clone from your fork instead.

2. Install a compiler with OpenMP support for your platform. See instructions for Windows, macOS, Linux and FreeBSD.

3. Optional (but recommended): create and activate a dedicated virtualenv or conda environment.

4. Install Cython and build the project with pip in Editable mode:

```
pip install cython
pip install --verbose --editable .
```

5. Check that the installed scikit-learn has a version number ending with .dev0:
6. Please refer to the Developer’s Guide and Useful pytest aliases and flags to run the tests on the module of your choice.

**Note:** You will have to re-run the `pip install --editable .` command every time the source code of a Cython file is updated (ending in `.pyx` or `.pxd`).

**Dependencies**

**Runtime dependencies**

Scikit-learn requires the following dependencies both at build time and at runtime:

- Python (>= 3.5),
- NumPy (>= 1.11),
- SciPy (>= 0.17),
- Joblib (>= 0.11).

Those dependencies are **automatically installed by pip** if they were missing when building scikit-learn from source.

**Note:** For running on PyPy, PyPy3-v5.10+, Numpy 1.14.0+, and scipy 1.1.0+ are required. For PyPy, only installation instructions with pip apply.

**Build dependencies**

Building Scikit-learn also requires:

- Cython >= 0.28.5
- A C/C++ compiler and a matching OpenMP runtime library. See the platform system specific instructions for more details.

**Note:** If OpenMP is not supported by the compiler, the build will be done with OpenMP functionalities disabled. This is not recommended since it will force some estimators to run in sequential mode instead of leveraging thread-based parallelism. Setting the `SKLEARN_FAIL_NO_OPENMP` environment variable (before cythonization) will force the build to fail if OpenMP is not supported.

Since version 0.21, scikit-learn automatically detects and use the linear algebra library used by SciPy at runtime. Scikit-learn has therefore no build dependency on BLAS/LAPACK implementations such as OpenBlas, Atlas, Blis or MKL.

**Test dependencies**

Running tests requires:

- `pytest` >=4.6.2
Some tests also require pandas.

**Building a specific version from a tag**

If you want to build a stable version, you can `git checkout <VERSION>` to get the code for that particular version, or download an zip archive of the version from github.

**Editable mode**

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. Therefore it is recommended that you install in with the `pip install --editable .` command, which allows you to edit the code in-place. This builds the extension in place and creates a link to the development directory (see the pip docs).

This is fundamentally similar to using the command `python setup.py develop` (see the setuptools docs). It is however preferred to use pip.

On Unix-like systems, you can equivalently type `make` in from the top-level folder. Have a look at the [Makefile](https://github.com/scikit-learn/scikit-learn/blob/master/setup.py) for additional utilities.

**8.6.3 Platform-specific instructions**

Here are instructions to install a working C/C++ compiler with OpenMP support to build scikit-learn Cython extensions for each supported platform.

**Windows**

Secondly, find out if you are running 64-bit or 32-bit Python. The building command depends on the architecture of the Python interpreter. You can check the architecture by running the following in `cmd` or `powershell` console:

```
python -c "import struct; print(struct.calcsize('P') * 8)"
```

For 64-bit Python, configure the build environment with:

```
SET DISTUTILS_USE_SDK=1
"C:\Program Files (x86)\Microsoft Visual_\2019\BuildTools\VC\Auxiliary\Build\vcvarsall.bat" x64
```

Replace `x64` by `x86` to build for 32-bit Python.

Please be aware that the path above might be different from user to user. The aim is to point to the “vcvarsall.bat” file that will set the necessary environment variables in the current command prompt.

Finally, build scikit-learn from this command prompt:

```
pip install --verbose --editable .
```
macOS

The default C compiler on macOS, Apple clang (confusingly aliased as /usr/bin/gcc), does not directly support OpenMP. We present two alternatives to enable OpenMP support:

- either install conda-forge::compilers with conda;
- or install libomp with Homebrew to extend the default Apple clang compiler.

macOS compilers from conda-forge

If you use the conda package manager (version >= 4.7), you can install the compilers meta-package from the conda-forge channel, which provides OpenMP-enabled C/C++ compilers based on the llvm toolchain.

First install the macOS command line tools:

```
xcode-select --install
```

It is recommended to use a dedicated conda environment to build scikit-learn from source:

```
conda create -n sklearn-dev python numpy scipy cython joblib pytest \
    conda-forge::compilers conda-forge::llvm-openmp
conda activate sklearn-dev
make clean
pip install --verbose --editable .
```

**Note:** If you get any conflicting dependency error message, try commenting out any custom conda configuration in the $HOME/.condarc file. In particular the channel_priority: strict directive is known to cause problems for this setup.

You can check that the custom compilers are properly installed from conda forge using the following command:

```
conda list compilers llvm-openmp
```

The compilers meta-package will automatically set custom environment variables:

```
echo $CC
echo $CXX
echo $CFLAGS
echo $CXXFLAGS
echo $LDFLAGS
```

They point to files and folders from your sklearn-dev conda environment (in particular in the bin/, include/ and lib/subfolders). For instance -L/path/to/conda/envs/sklearn-dev/lib should appear in LDFLAGS.

In the log, you should see the compiled extension being built with the clang and clang++ compilers installed by conda with the -fopenmp command line flag.

macOS compilers from Homebrew

Another solution is to enable OpenMP support for the clang compiler shipped by default on macOS.

First install the macOS command line tools:
xcode-select --install

Install the Homebrew package manager for macOS.
Install the LLVM OpenMP library:

brew install libomp

Set the following environment variables:

```
export CC=/usr/bin/clang
export CXX=/usr/bin/clang++
export CPPFLAGS="$CPPFLAGS -Xpreprocessor -fopenmp"
export CFLAGS="$CFLAGS -I/usr/local/opt/libomp/include"
export CXXFLAGS="$CXXFLAGS -I/usr/local/opt/libomp/include"
export LDFLAGS="$LDFLAGS -Wl,-rpath,/usr/local/opt/libomp/lib -L/usr/local/opt/libomp/
  -lomp"
```

Finally, build scikit-learn in verbose mode (to check for the presence of the -fopenmp flag in the compiler commands):

```
make clean
pip install --verbose --editable .
```

### Linux

**Linux compilers from the system**

Installing scikit-learn from source without using conda requires you to have installed the scikit-learn Python development headers and a working C/C++ compiler with OpenMP support (typically the GCC toolchain).

Install build dependencies for Debian-based operating systems, e.g. Ubuntu:

```
sudo apt-get install build-essential python3-dev python3-pip
```

then proceed as usual:

```
pip3 install cython
pip3 install --verbose --editable .
```

Cython and the pre-compiled wheels for the runtime dependencies (numpy, scipy and joblib) should automatically be installed in `$HOME/.local/lib/pythonX.Y/site-packages`. Alternatively you can run the above commands from a `virtualenv` or a `conda environment` to get full isolation from the Python packages installed via the system packager. When using an isolated environment, `pip3` should be replaced by `pip` in the above commands.

When precompiled wheels of the runtime dependencies are not available for your architecture (e.g. ARM), you can install the system versions:

```
sudo apt-get install cython3 python3-numpy python3-scipy
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```
sudo yum -y install gcc gcc-c++ python3-devel numpy scipy
```
Linux compilers from conda-forge

Alternatively, install a recent version of the GNU C Compiler toolchain (GCC) in the user folder using conda:

```
conda create -n sklearn-dev numpy scipy joblib cython conda-forge::compilers
conda activate sklearn-dev
pip install --verbose --editable .
```

FreeBSD

The clang compiler included in FreeBSD 12.0 and 11.2 base systems does not include OpenMP support. You need to install the openmp library from packages (or ports):

```
sudo pkg install openmp
```

This will install header files in `/usr/local/include` and libs in `/usr/local/lib`. Since these directories are not searched by default, you can set the environment variables to these locations:

```
export CFLAGS="$CFLAGS -I/usr/local/include"
export CXXFLAGS="$CXXFLAGS -I/usr/local/include"
export LDFLAGS="$LDFLAGS -L/usr/local/lib -lomp"
```

Finally, build the package using the standard command:

```
pip install --verbose --editable .
```

For the upcoming FreeBSD 12.1 and 11.3 versions, OpenMP will be included in the base system and these steps will not be necessary.

8.7 Maintainer / core-developer information

8.7.1 Before a release

1. Update authors table:

```
$ cd build_tools; make authors; cd ..
```

and commit.

2. Confirm any blockers tagged for the milestone are resolved, and that other issues tagged for the milestone can be postponed.

3. Ensure the change log and commits correspond (within reason!), and that the change log is reasonably well curated. Some tools for these tasks include:

   - `maint_tools/sort_whats_new.py` can put what’s new entries into sections.
   - The `maint_tools/whats_missing.sh` script may be used to identify pull requests that were merged but likely missing from What’s New.
Preparing a bug-fix-release

Since any commits to a released branch (e.g. 0.999.X) will automatically update the web site documentation, it is best to develop a bug-fix release with a pull request in which 0.999.X is the base. It also allows you to keep track of any tasks towards release with a TO DO list.

Most development of the bug fix release, and its documentation, should happen in master to avoid asynchrony. To select commits from master for use in the bug fix (version 0.999.3), you can use:

```
$ git checkout -b release-0.999.3 master
$ git rebase -i 0.999.X
```

Then pick the commits for release and resolve any issues, and create a pull request with 0.999.X as base. Add a commit updating `sklearn.__version__`. Additional commits can be cherry-picked into the `release-0.999.3` branch while preparing the release.

8.7.2 Making a release

1. Update docs:
   - Edit the `doc/whats_new.rst` file to add release title and commit statistics. You can retrieve commit statistics with:
     ```
     $ git shortlog -s 0.99.33.. | cut -f2- | sort --ignore-case | tr \n 'i' \n | sed 's/;\n/;/g;s/, $/\n'
     ```
   - Update the release date in `whats_new.rst`
   - Edit the `doc/index.rst` to change the ‘News’ entry of the front page.
   - Note that these changes should be made in master and cherry-picked into the release branch.

2. On the branch for releasing, update the version number in `sklearn/__init__.py`, the `__version__` variable by removing `dev*` only when ready to release. On master, increment the version in the same place (when branching for release).

3. Create the tag and push it:
   ```
   $ git tag -a 0.999
   $ git push git@github.com:scikit-learn/scikit-learn.git --tags
   ```

4. Create the source tarball:
   - Wipe clean your repo:
     ```
     $ git clean -xfd
     ```
   - Generate the tarball:
     ```
     $ python setup.py sdist
     ```
   The result should be in the `dist/` folder. We will upload it later with the wheels. Check that you can install it in a new virtualenv and that the tests pass.

5. Update the dependency versions and set `BUILD_COMMIT` variable to the release tag at:
   ```
   https://github.com/MacPython/scikit-learn-wheels
   ```
Once the CI has completed successfully, collect the generated binary wheel packages and upload them to PyPI by running the following commands in the scikit-learn source folder (checked out at the release tag):

```
$ rm -r dist
$ pip install -U wheelhouse_uploader twine
$ python setup.py fetch_artifacts
```

6. Check the content of the `dist/` folder: it should contain all the wheels along with the source tarball (“scikit-learn-XXX.tar.gz”).

Make sure that you do not have developer versions or older versions of the scikit-learn package in that folder.

Upload everything at once to https://pypi.org:

```
$ twine upload dist/*
```

7. For major/minor (not bug-fix release), update the symlink for stable and the latestStable variable in https://github.com/scikit-learn/scikit-learn.github.io:

```
$ cd /tmp
$ git clone --depth 1 --no-checkout git@github.com:scikit-learn/scikit-learn.github.io
$ cd scikit-learn.github.io
$ echo stable > .git/info/sparse-checkout
$ git checkout master
$ rm stable
$ ln -s 0.999 stable
$ sed -i "s/latestStable = '.*/latestStable = '0.999';" versionwarning.js
$ git commit -m "Update stable to point to 0.999" stable
$ git push origin master
```

The following GitHub checklist might be helpful in a release PR:

- [ ] update news and what's new date in master and release branch
- [ ] create tag
- [ ] update dependencies and release tag at https://github.com/MacPython/scikit-learn-wheels
- [ ] twine the wheels to PyPI when that's green
- [ ] https://github.com/scikit-learn/scikit-learn/releases draft
- [ ] confirm bot detected at https://github.com/conda-forge/scikit-learn-feedstock
- [ ] https://github.com/scikit-learn/scikit-learn/releases publish
- [ ] announce on mailing list
- [ ] (regenerate Dash docs: https://github.com/Kapeli/Dash-User-Contributions/tree/master/docsets/Scikit)

### 8.7.3 The scikit-learn.org web site

The scikit-learn web site (http://scikit-learn.org) is hosted at GitHub, but should rarely be updated manually by pushing to the https://github.com/scikit-learn/scikit-learn.github.io repository. Most updates can be made by pushing to master (for /dev) or a release branch like 0.99.X, from which Circle CI builds and uploads the documentation automatically.

### 8.7.4 Travis Cron jobs

From https://docs.travis-ci.com/user/cron-jobs: Travis CI cron jobs work similarly to the cron utility, they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository. Cron jobs always
fetch the most recent commit on a particular branch and build the project at that state. Cron jobs can run daily, weekly or monthly, which in practice means up to an hour after the selected time span, and you cannot set them to run at a specific time.

For scikit-learn, Cron jobs are used for builds that we do not want to run in each PR. As an example the build with the dev versions of numpy and scipy is run as a Cron job. Most of the time when this numpy-dev build fail, it is related to a numpy change and not a scikit-learn one, so it would not make sense to blame the PR author for the Travis failure.

The definition of what gets run in the Cron job is done in the .travis.yml config file, exactly the same way as the other Travis jobs. We use a `if: type = cron` filter in order for the build to be run only in Cron jobs.

The branch targeted by the Cron job and the frequency of the Cron job is set via the web UI at https://www.travis-ci.org/scikit-learn/scikit-learn/settings.

### 8.7.5 Experimental features

The `sklearn.experimental` module was introduced in 0.21 and contains experimental features / estimators that are subject to change without deprecation cycle.

To create an experimental module, you can just copy and modify the content of `enable_hist_gradient_boosting.py`, or `enable_iterative_imputer.py`.

Note that the public import path must be to a public subpackage (like `sklearn/ensemble` or `sklearn/impute`), not just a `.py` module. Also, the (private) experimental features that are imported must be in a submodule/subpackage of the public subpackage, e.g. `sklearn/ensemble/_hist_gradient_boosting/` or `sklearn/impute/_iterative.py`. This is needed so that pickles still work in the future when the features aren’t experimental anymore.

Please also write basic tests following those in `test_enable_hist_gradient_boosting.py`.

Make sure every user-facing code you write explicitly mentions that the feature is experimental, and add a `# noqa` comment to avoid pep8-related warnings:

```python
# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
```

For the docs to render properly, please also import `enable_my_experimental_feature` in `doc/conf.py`, else sphinx won’t be able to import the corresponding modules. Note that using from `sklearn.experimental` import * does not work.

Note that some experimental classes / functions are not included in the `sklearn.experimental` module: `sklearn.datasets.fetch_openml`.

### 8.8 Developing with the Plotting API

Scikit-learn defines a simple API for creating visualizations for machine learning. The key features of this API is to run calculations once and to have the flexibility to adjust the visualizations after the fact. This section is intended for developers who wish to develop or maintain plotting tools. For usage, users should refer to the `User Guide <visualizations>`.

#### 8.8.1 Plotting API Overview

This logic is encapsulated into a display object where the computed data is stored and the plotting is done in a `plot` method. The display object’s `__init__` method contains only the data needed to create the visualization. The `plot`
method takes in parameters that only have to do with visualization, such as a matplotlib axes. The plot method will store the matplotlib artists as attributes allowing for style adjustments through the display object. A plot_* helper function accepts parameters to do the computation and the parameters used for plotting. After the helper function creates the display object with the computed values, it calls the display’s plot method. Note that the plot method defines attributes related to matplotlib, such as the line artist. This allows for customizations after calling the plot method.

For example, the RocCurveDisplay defines the following methods and attributes:

```python
class RocCurveDisplay:
    def __init__(self, fpr, tpr, roc_auc, estimator_name):
        ...
        self.fpr = fpr
        self.tpr = tpr
        self.roc_auc = roc_auc
        self.estimator_name = estimator_name

    def plot(self, ax=None, name=None, **kwargs):
        ...
        self.line_ = ...
        self.ax_ = ax
        self.figure_ = ax.figure

    def plot_roc_curve(self, estimator, X, y, pos_label=None, sample_weight=None, drop_intermediate=True, response_method="auto", name=None, ax=None, **kwargs):
        # do computation
        viz = RocCurveDisplay(fpr, tpr, roc_auc, estimator.__class__.__name__)
        return viz.plot(ax=ax, name=name, **kwargs)
```

Read more in ROC Curve with Visualization API and the User Guide.

### 8.8.2 Plotting with Multiple Axes

Some of the plotting tools like `plot_partial_dependence` and `PartialDependenceDisplay` support plotting on multiple axes. Two different scenarios are supported:

1. If a list of axes is passed in, `plot` will check if the number of axes is consistent with the number of axes it expects and then draws on those axes. 2. If a single axes is passed in, that axes defines a space for multiple axes to be placed. In this case, we suggest using matplotlib’s `GridSpecFromSubplotSpec` to split up the space:

```python
import matplotlib.pyplot as plt
from matplotlib.gridspec import GridSpecFromSubplotSpec

fig, ax = plt.subplots()
gs = GridSpecFromSubplotSpec(2, 2, subplot_spec=ax.get_subplotspec())
ax_top_left = fig.add_subplot(gs[0, 0])
ax_top_right = fig.add_subplot(gs[0, 1])
ax_bottom = fig.add_subplot(gs[1, :])
```

By default, the `ax` keyword in `plot` is `None`. In this case, the single axes is created and the gridspec api is used to create the regions to plot in.

See for example, `plot_partial_dependence` which plots multiple lines and contours using this API. The axes defining the bounding box is saved in a `bounding_ax` attribute. The individual axes created are stored in an `axes_`
ndarray, corresponding to the axes position on the grid. Positions that are not used are set to None. Furthermore, the matplotlib Artists are stored in lines_ and contours_ where the key is the position on the grid. When a list of axes is passed in, the axes_, lines_, and contours_ is a 1d ndarray corresponding to the list of axes passed in.
